A Monster.—A human monster, a female child with two heads, was born a few days ago at Zerbst. A careful examination has shown that the spinal column divided into two at the first of the true vertebræ, and that from this point two perfectly developed necks and head proceed. The breast is half as broad again as is usual, the limbs simple and well formed. We have not yet heard in how far the internal construction of the breast is simple or complex. It appears that the child died in the course of birth, from the pressure of the two heads against each other.—*Galignani.*

Royal Hospital for Diseases of the Chest.—The annual meeting was held last week at the hospital, City-road. The Secretary read the report, which stated that during the year 142 in-patients and 3,772 out-patients had been relieved. Mr. J. G. Glyn, M.P., had resigned the office of treasurer, on his important appointment in the House of Commons, which had been subsequently filled by the late treasurer's brother, Mr. Pascoe C. Glyn. The receipts from all sources had been 2,090*l.*, while the expenditure had amounted to 2,413*l.*, showing a balance due to the treasurer of 323*l.* The report having been received and adopted it was announced that H.R.H. Duke of Cambridge had consented to take the chair at the forthcoming annual dinner.

The Great Northern Hospital.—The triennial festival in aid of the funds of the Great Northern Hospital, Caledonian road, was celebrated last week, when about 150 gentlemen sat down to dinner under the presidency of Lord Houghton. From the annual report of the institution it appears that this hospital on account of its proximity to two of the large metropolitan railway stations and the cattle market, is peculiarly subject to the influx of dangerous casualties and the pressure on the accommodation is very great. The hospital has recently entered upon enlarged premises, and it possesses a large out-patients' department, which is daily frequented by a large number of sick poor. An average of 400 new patients are admitted each week. For the new premises the committee have paid 6,000*l.*, leaving a debt of 3,000*l.* still to be removed. During the twelve months ending on the 30th June last 56,045 out-patients were relived, and 297 in-patients, a total number of 590,093 patients having been relieved since the hospital opened in 1856. In the course of the evening, Lord Houghton in an appropriate speech urged the claims of the institution upon the support of the benevolent so successfully that the sum of 667*l.* 1s. was announced as having been contributed to the funds of the hospital in the course of the evening.

Medical Society of London.—The ninety-sixth anniversary dinner of this Society was celebrated at the Albion Tavern, on Monday, the 8th inst., under the presidency of Dr. Richardson. Amongst the distinguished guests, were Sir Wm. Fergusson, Bart., the President of the Clinical Society Mr. Paget), the President of the Obstetrical Society (Dr. Graily Hewett) ,Mr. Hepworth Dixon, &c. &c. Nearly 70 Fellows of the Society were present, and the evening passed off with *eclat*, previous to the dinner, Sir Duncan Gibb delivered the Annual Oration after which, the President, with a few appropriate remarks, presented the Silver Medals for the year—one to the retiring Secretary Mr. Francis Mason, the other to Dr. Henry Day of Stafford, and the Diploma of the honorary Fellowship to Dr. C. J. Hare, one of the past Presidents. The following is a list of the newly elected Officers and Council for the ensuing session. *List of Officers and Council for* 1869-70.—President:—Peter Marshall, Esq.; Vice Presidents:—John Gay, Esq; George Buchanan, M.D.; Andrew Clark, M.D.; William Adams, Esq.; Treasurer: C. H. Rogers-Harrison, Esq; Librarian:—S. Day-Goss, M.D.; Secretaries in Ordinary:—A. Ernest Sansom, M.D., J. Wickham Barnes, Esq.; Secretary for foreign correspondence:—J. Althaus, M.D.; Councillors:—W. Cholmeley, M.D., C. Cogswell, M.D., Victor de Méric, Esq., R. W. Dunn, Esq., W. Tilbury Fox, M.D., E. Head, M.D., Abbotts Smith, M.D., E. Symes Thompson, M.D., W. Spencer Watson, Esq, F. E. Anstie, M.D., Henry Day, M.D. (Stafford), William Harvey, Esq., James Hinton Esq., Thomas Hunt, Esq., Hughlings Jackson, M.D., B. W. Richardson, M.D., H. Hyde Salter, M.D., Frederick Simms, M.B., Gregory Smith, Esq., J. L. W. Thudichum, M.D.; Orator:—Francis Mason, Esq.

NOTICES TO CORRESPONDENTS.

Mr. W. S. Whatford, Brighton.—In an early number.

Notes on a visit to some of the Skin Hospitals of Great Britain, by H. S. Purdon, M.D., Physician to the Belfast Skin Hospital, received.

J. Lamprey, M.D., Portsmouth, is thanked for the following papers to hand:—"Three Cases of Aneurism of the Aorta, with Rupture into the Pericardium," and "On a New Method of Making the Interrupted Suture by means of fine Sewing Needles." Dr. Lamprey shall receive a private note when the cost of illustrating his papers has been ascertained.

Dr. George Down will please received our best thanks.

SHIP APPOINTMENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Would you be so kind as to inform me, through the columns of your Journal, what the best mode of procedure would be in order to secure an appointment as surgeon to one of the steam ships plying between this country and America. I have applied more than once to some of those so-called "agents," but without success. Also the remuneration given to a surgeon for his services, or whether there be a fixed stipend for the voyage? By doing so you will greatly oblige,

Yours faithfully,

A Subscriber.

⁂ "*Apropos* of ship appointments, they are mostly secured by private interest; those under the Commissioners of Emigration are subject to great competition; the Peninsular and Oriental Company's appointments are still more eagerly sought, and are, therefore, more difficult to secure; next, perhaps, in order, might be placed some of the private firms, and the American packets. The Royal Mail service is more accessible, because all the new appointments are made to the West India stations, from which the medical officers are promoted to other and more eligible stations. Some very respectable agents give their special attention to such appointments."

We are not aware of the remuneration given to surgeons on board these ships. See "Students Number" of this Journal for 1868.

Wild.—On the 15th March, George Wild, M.R.C.S., &c., Cowley road, Brixton.

NOTICE TO ADVERTISERS.

The Medical Press and Circular
OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales, and Transfers of Practices, Surgical Instruments Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under..............	£0	3s.	6d.
Per line afterwards..................	0	0s.	6d.
One-quarter page.....................	1	5s.	0d.
Half ,, ...	2	5s.	0d.
One ,, ...	4	0s.	0d.

The average of words per line is twelve.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the Office, on Saturday, by Two o'Clock.

ANATOMICAL, SURGICAL, AND ORTHOPŒDIC MECHANICIAN,

29 Leicester square, W.C.

SIR,

Having succeeded to the Business carried on for so long a period at the above address, and to which I have been Managing Assistant for thirty years, I beg to solicit a continuance of those favours which have hitherto been so liberally bestowed.

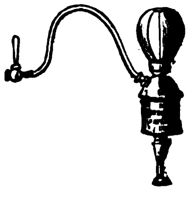
I take this opportunity of informing you that my great experience in the Military and other Hospitals, together with private cases of a very numerous kind, render me fully competent to undertake and carry out any instructions entrusted to me.

Should my services at any time be required, I shall be at your commands.

I beg to remain, Sir,

Your obedient servant,

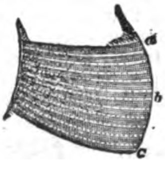
WILLIAM MILLER.



TWINBERROW'S PATENT DOUBLE-ACTION SYPHON SYRINGE, with Additional Pipes for all purposes, possesses these advantages:—1. It is without a piston; therefore, There is no exertion required in its use. As the stream flows uninterruptedly, double the Quantity is discharged in half the usual time, with double effect.

From J. ERICHSEN, Esq., Professor of Surgery at University College: "Twinberrow's double-action syphon syringe is the most generally useful Instrument of the kind with which I am acquainted, being compact, portable, and not liable to get out of order. It may be rendered available as an Eye Douche, an Ear Syringe, and for washing out the bladder. For these purposes it is peculiarly well adapted, being continuous in its action."—From Sir W. FERGUSSON, Bart., Professor of Surgery at King's College: "I have seen and made use of your Double-Action Syringe, and think very highly of it."

TWINBERROW & SON, Dispensing Chemists, Sole Patentees.
2, Edwards-st., Portman-square, and 45, Westbourne-grove, London.

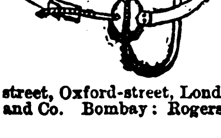


HUXLEY'S SPIRAL ABDOMINAL BELTS, for Pregnancy, Obesity, Ovarian Disease, and Air-pads for Hernia. Made on principles approved by the first Physician-Accoucheurs and Surgeons. Directions for measurements: circumference, at *a*, *b*, *c*; depth, from *a* to *c*. Discount to the profession, 20 per cent.

HUXLEY'S OBSTETRIC BINDER, 3s. 6d. Illustrated and Priced Circulars on application to

ED. HUXLEY, 12, Old Cavendish street, Oxford street, London.

(NO STEEL BAND.)



HUXLEY'S PATENT MOC-MAIN TRUSS, in which the troublesome lever spring is entirely dispensed with, is acknowledged by hundreds of wearers to be the most comfortable and efficacious Truss yet devised.

Prices, to the Profession only: Single, 9s. and 12s. Double, 14s. 3d. and 17s.,—nett.

ED. HUXLEY, 12, Old Cavendish-street, Oxford-street, London. Agents for Calcutta: Messrs. Bathgate and Co. Bombay: Rogers and Co. Montreal: R. Birks.

ON STRICTURE OF THE RECTUM.

By Holmes Coote, F.R.C.S.,

Surgeon to St. Bartholomew's Hospital.

Contractions of the rectum may proceed from inflammatory effusion and from thickening of the walls of the gut, or from cancerous deposit. According to my experience the latter is the more common, especially when the patient has passed the middle period of life.

The following remarks refer only to the non-malignant variety of stricture of the rectum.

Now the œsophagus and the rectum, the two extremities of the alimentary canal, are, though both exposed to causes inducing contraction, placed in a somewhat different physiological condition. The food, properly masticated and softened, passes rapidly down the former passage. But in the rectum, the fæces, often hard and accumulated in abnormal amount, may be allowed to remain, giving rise to local disturbance, and occasionally to a state of general illness. I have not seen many cases of stricture of the œsophagus that were not associated with cancer. In one case the cause was the contraction of a large cicatrix covering an ulcer made by the action of strong nitric acid on the mucous membrane, the patient having made an attempt to commit suicide. In another case the canal of the œsophagus, just below the level of the cricoid cartilage, was reduced to a quarter of an inch in diameter, and was flattened from before backwards. The tissues around were thickened, indurated, and consolidated. Above the stricture there was the ulcerated aperture of an abscess. Below the stricture the mucous membrane was healthy. Patients have also presented themselves with symptoms of spasmodic stricture, which were relieved by general treatment and the careful use of the bougie.

The museum of the hospital gives the following illustration of non-malignant strictures of the rectum. Series xvi No. 31. Portion of a rectum, the cavity of which, at its upper part, is contracted to a quarter of an inch in diameter without any visible change of structure. The contraction includes about an inch of the length of the intestine, and was probably occasioned by the action of the muscular fibres. No. 32 shows a case of general thickening and induration of the coats of the rectum, and a close annular stricture from two to three inches from the anus. Above the stricture the intestine is dilated, and the muscular coat is thick and strong; below it, there is diffuse superficial ulceration of the mucous membrane. Another specimen shows annular contraction, with thickening induration and superficial ulceration of its coats in the line of junction of the colon with the rectum. It was so close and firm that a finger could not be passed through it: except at this spot the rectum was healthy. Several specimens show contraction of large portions of the canal. In one specimen, just above the anus, numerous ulcerated apertures, with smooth edges, led through the walls of the rectum into short fistulous canals in the surrounding indurated tissue. One of the canals extended through the coats of the bladder into the cavity. The whole tube of the rectum is narrowed. A middle-aged woman suffered many years from stricture of the rectum. After death it was found that the mucous membrane had been completely removed by ulceration to the extent of several inches above the anus. Abscesses had formed around and burst into the tube, and all the tissues were indurated and contracted. I have met with several cases of a thickened and tuberculated condition of the mucous membrane of the rectum in young girls, most of whom, however, had been leading a life of prostitution; indeed, I have at the present time a girl so affected under my care. The early stage of this disease may be illustrated by the following specimen. No. 64. The rectum of a girl, aged twenty-five. The mucous membrane is entirely removed by ulceration for several inches above the anus, and above the ulcerated part it is slightly thickened. In the more advanced stage we find the coats of the intestine generally thickened and of very dense texture, the mucous membrane in some situations tuberculated, and in others ulcerated, and the cellular and adipose tissue around indurated. After a time the coats of the bladder may undergo the same change of structure.

Beside this we meet with yet another change. The cavity of the rectum may be contracted from two inches above the anus upwards for three to five inches. The coats become thickened and indurated; the divided edges exhibit white bands intersecting a very firm substance. The cellular tissues about the rectum are also thickened and converted into a hard brawny substance, in which the posterior surfaces of the uterus vagina and broad ligaments are often involved.

Thus we are justified in asserting that stricture of the rectum may be induced by prolonged irritation, leading to inflammatory induration, and to ulceration; the mucous membrane may become tuberculated; the surrounding tissues similarly changed, and, finally, adjacent organs also become involved and adherent. Of all causes, habitual constipation is the most frequent, and it is remarkable to what an extent in some persons fæcal accumulations are allowed to proceed. Some short time ago, being in a large country mansion to see professionally a lady somewhat advanced in years, I was surprised to find the only water-closet on the ground floor, at the end of some long and intricate passages. When commenting on the slight inconvenience of such an arrangement to the inmates, I was informed that the lady of the house rarely had an action of the bowels more than once a week.

Both Mr. Travers and Mr. Ashton mention cases, in one of which an excessive growth of fat, and in the second a "large mass, very dense, and having the appearance of fat, but in reality composed of fibrous tissue alone," were the causes of stricture.

(To be continued.)

◆

ON THE MODE OF ACTION OF THE CHOLERA POISON.

By Arthur Ernest Sansom, M.D. Lond., M.R.C.P.,

Physician to the Royal Hospital for Diseases of the Chest, City Road.

(Continued from page 201.)

We have now to consider the probable mode by which the germs of cholera produce the flux from the intestinal canal. We may divide the duration of the flux into two periods—the one in which there is such evacuation as obtains in ordinary diarrhœa, *i. e.*, a looseness without any specific character; the other in which is the condition known as "rice-water evacuation." If we agree that the cholera poison is directly transmitted to the surface of the gastro-intestinal tract, we may, with much *prima facie* probability, assign these effects to its irritant action upon the structures—an irritation which differs in degree, and so produces the diarrhœal (pre-choleraic) or the true choleraic flow.

Pathological anatomy teaches that in greater or less degree the whole alimentary tract presents signs of morbid action in cases of cholera. The pharynx and œsophagus have, in some cases, presented their mucous lining covered with soft pulpy detritus. The stomach has been found thickened as to its lining membrane, its solitary glands enlarged, and tenacious mucus and exfoliated epithelium free within its cavity. The intestines have shown signs of denudation of their epithelium; from patches of the mucous surface villi have been found completely detached; the glands of the intestines have been found enlarged. In the interior of the intestines have been found the shed epithelium and the detached villi, together with stringy and laminated mucus, hæmatin mingled with many organised bodies, evidently derived from the vegetable world, and vibriones and other infusoria in myriads. All these signs are consistent with the hypothesis of a cause which is a direct and violent irritant of the lining structures of the alimentary tract. So, also, is the evidence afforded by the examination of the evacuations themselves. It has been argued that the rice-water stools owe the peculiar flocculent appearance which they possess to the presence of epithelium; that, therefore, there must be, during the choleraic attack, not only a falling-off of the epithelial particles lining the intestinal canal, but also a rapid formation, growth, decay, and decadence of successive generations of epithelium. Further investigation has shown that this view is not tenable: the greater part of the denuded epithelium passes away in the stage of simple diarrhœa; that which gives the flocculent character to the rice-water stools is not epithelium, but *fibrillated mucus* carried down by the albumino-saline liquid excretion.

The signs, however, do not admit the hypothesis of an irritant cause acting in a definite manner upon definite portions of the canal, as an inorganic irritant would act. It would seem that there are *foci* and *loci* in which the disease-producing molecules manifest their morbid activity; and this is just what, according to our own theory of causation by organised particles, we should expect. The cholera-genic molecules, swallowed under circumstances which permit of their active vitality, become irritants of the whole mucous tract. They find amid the epithelial cells of the alimentary canal a soil in which they can multiply with great rapidity; and, just as fungi of a larger growth will in a single night lift up by their development a heavy stone, so these increasing within and around the individual epithelial cells detach such cells from the subjacent tissues. Hence the irritation which excites the action of the bowels, and induces the diarrhœal flow; thus, the epithelial cells, with some of the countless germs which have induced this exfoliation, become carried away from the organism, while others remain behind to continue their fatal work; thus, also, are produced (the epithelium being stripped from their surface) the eroded portions of the intestinal tract.

Such are the views of those observers who hold to the fungous origin of cholera. It has seemed to me that the theory accounts for the symptoms with a great amount of plausibility, although, as I said before, I wholly demur to any conclusion which avers of such or such organised particle, "this is the efficient agent in producing cholera." I hold that whatever is observed may be but the index of what is not observed, and that, though certain bodies may be concomitants of the proliferation of organised bodies which are the disease producers, we are not justified in concluding that they are themselves the *veræ causæ*.

I have not observed, however, that in this question any analogical experimentation has been adopted. One of the first questions which I conceive to arise is—Have we any evidence that fermentation (growth of living vegetable particles) can take place within the living body, and can produce, *proprio motu*, morbid symptoms? Of course, it is known that in circumstances in which aliment is retained in the stomach, fermentation with the development of torulæ and of sarcinæ can and does take place; but I do not know of any synthetic researches on this question. I have myself put the matter to a practical test, and I think the lessons cannot fail to be of much value.

Fermentation within the living body.—In September, 1868, I was engaged in microscopic observations upon fermentation, the growth of yeast torulæ, and the effects of the sulphites upon the process. I determined to try whether the phenomena could take place within the stomach of an animal. I therefore mixed together German yeast and rice powder, and gave them as food to a healthy white mouse. The mixture was readily eaten by the animal, but twenty-four hours afterwards it was found panting and dying. Having given chloroform vapour to kill, I immediately examined the body. I found the *stomach* filled with a brownish red substance, which, on examination, proved to consist of stomach tubes detached from the walls of the viscus, a mass of cells of shed epithelium, together with vegetable spores and fragments of torulæ. Portions of the stomach wall were completely denuded, the exposed membrane presenting the appearance of thin parchment. The *intestines*, small and large, were also filled with shed epithelium and vegetable germs in active reproduction. Numerous entozoa were also found; larvæ of tænia were found in abundance, especially in the appendix vermiformis, and a large tænia crassicollis was found in the liver. The *excrement* contained branching torulæ.

I repeated this experiment with similar results. Then, from observation of the German yeast, I thought it might be contaminated with ova and germs other than vegetable. I determined to try the effects simply of brewers' yeast and sugar. Accordingly, I supplied three mice merely with this pabulum. At the end of forty-nine hours they were all found dying. I killed them with chloroform, and immediately examined them. The appearances now were still more striking. The stomach contained a mass consisting of torulæ (arrived at a far higher stage of development than those obtained by fermentation for a like period outside the body), intertwined among masses of epithelial cells. In every case the posterior part of the stomach wall was completely denuded. In every part of the *intestines*, also, was there desquamation of epithelium, and actively growing torulæ were observed.

I consider that these observations afford experimental proof—

1. That vegetable organisms can grow and multiply within the living body.
2. That by their growth and multiplication they can produce lesions of the intestinal canal.
3. That the lesions thus produced by fermenting matter in the case of the mouse bear a striking similarity to those observed in cholera in the case of man.

(To be continued.)

◆

ON INFANTICIDE AND ABORTION AS *SUGGESTED* INSTITUTIONS.

By Ewing Whittle, M.D., M.R.I.A.,
Lecturer on Medical Jurisprudence and Toxicology to the Liverpool Royal Infirmary School of Medicine.

Our profession has recently been startled by a suggestion publicly made, and apparently emanating from high authority, that its members should lend themselves to some scheme of limiting the numbers of children born into families. I allude to the proceedings of a London society called the "Dialectical," who, not long since, in a discussion on the "Happiness of the community as affected by large families," boldly started the assumptions that large families were an unquestionable evil, that population increased too fast for the means of subsistence, that the indispensable remedy lay in the limiting of the number of births; and the medical profession was appealed to by this society of political economists to devise some scheme by which this purpose could be effected without injury to the health of the married couples who might be induced to enter upon this struggle with nature to keep down the natural growth of our species.

The experience of mankind has ever held in honour the fathers of large families. Even now in healthy society they are ever looked up to with honour and respect. The holy writings teach that large families are a special blessing from heaven. "Lo, children and the fruit of the womb are an heritage and gift that cometh of the Lord. Like as arrows in the hand of a giant, even so are young children. Happy is the man that has his quiver full of them." And, again, "Thy wife shall be as the fruitful vine, thy children like the olive branches, round about thy table. Lo, thus shall the man be blessed that feareth the Lord."

But our political economists of to-day, greater in their wisdom than either Solomon or David, reject with equal scorn the dictates of Revelation and the results of human experience, and boldly affirm that nature must be wrestled with, that the natural increase of births must be prevented, and have even the audacity to challenge the medical profession to become their accomplices in this wicked and base attempt to stay the course of God's providential government of the world.

The gauntlet being, as it were, thus thrown down to us, must be my apology for bringing this subject before you. You are aware the chairman of the society in question, Lord Amberly, has been severely criticised by the press for the remarks he is reported to have made on the occasion of the discussion. His lordship has since, it is true, repudiated to some extent the sentiments attributed to him; but the fact, nevertheless, remains that he identifies himself with the doctrines of Malthus; that he assumes an axiom "that we are tending to over-population, and that large families are an evil." He also compliments the ladies of America, as being in advance of us, by being in the habit of keeping back their families, though he does express disapprobation of their manner of effecting this purpose; this disapprobation, however, being rather directed against the injury to health, and not to morals.

In the course of this paper I shall bring under your notice a work, emanating from the same school of political economy, in which the practice of infanticide was openly recommended. This work was published in 1838, when Lord Russell was a Cabinet Minister, and no prosecution was instituted on the part of the Government against the publishers of this scandalous and infamous libel.

In our mind, the idea of making a legitimate practice of infanticide and artificial abortion, excite at once a feeling of disgust and horror, the more that it is not unfrequently a part of our duty to assist, by evidence, in bringing to punishment the authors of these crimes against society and against nature; indeed, these are not the feelings of medical men alone, but of all whose minds have not been contaminated by the specious sophisms of this pseudo-philosophy of which Malthus was the founder. To him pre-eminently belongs either the glory or the shame of such teaching. In the beginning of this century, and for some time afterwards, this theory of Malthus was accepted by political economists as the true theory of population, and anyone who thought of questioning it was regarded as a heretic among political economists. This slavish subjection to the monstrous propositions of Malthus continued without question and without reaction, until the growth of the doctrine culminated, in 1838, in the publication of the book that I have already referred to. As this book was very speedily suppressed, I am sure most of my younger readers have never seen it —possibly many of them have never heard of it. The title of this work was—*On the Possibility of Limiting Populousness.* By Marcus. It was issued in the form of a one-and-sixpenny pamphlet, the paper good, and the type elegant; it was evidently intended to circulate amongst the select, and was by no means intended for the enlightenment of the million. The author commences by glorifying Malthus as a great discoverer, and adds that he shrunk back appalled at the inevitable results to which his theory led. He then lays down four maxims, the substance of which were as follow:—

Maxim 1.—Excess of population is at once the main evil and the main cause of all the other evils that affect human society.

Maxim 2.—Every superfluous portion of population is not merely doomed itself to degradation and suffering, but is an agent force, ultimately deteriorating the whole social body in general.

Maxim 3.—Whenever society, by favour of a casual clearance of population, makes some progress, the return of the excess carries it back again.

Maxim 4.—The steps by which these effects take place are—the deterioration of morals, the cheapness of men, misery, and the discouragement to the efforts of the benevolent caused by the prospect of a fruitless enterprise, and a mortifying failure.

The author then moralizes on what he calls ideas hitherto entertained, foremost among which he places the phrase, "The strength of a country is the people." This self-evident truth he treats as an assumption, hardly worth the trouble of a refutation, and goes on to compare what he calls the great *ulcer of modern nations*, a proletarian population, with the *servile state* of antiquity. "The slaves of antiquity were cattle. Without much difficulty the sexes might be kept effectually separated, or, if the offspring came to be more than was wanted, it was destroyed as a matter of course. But, further, the practice of infanticide, rendered familiar by its frequency, was in no wise shocking when applied to the other part of the population—to the favoured slaves, to the freed men, and to the citizens themselves. Only being optional and not enforced, it did not reach the point we had in view; *the preventing the existence of persons for whom there were no places.* Still, this partial relief broke the force and importunity of the complaint."

The author then goes on to state that, "as slavery was abolished, the greatest of all disorders, procreation without rule or limit, would pass unprohibited and unheeded. The truth is, this great change came about surreptitiously. It never was deliberated or accorded by any law giver or law giving body. Up to this day, then, the omission has been rectified. The condition in the bargain of liberty remains still to be imposed and enforced, the means of enforcing it are to be invented, and the delicate task of introducing a new practice is yet to be performed."

In the brief quotations that I have instanced from the first two chapters of this daring publication, there is not a shadow of an attempt even to prove the first maxim, that an excess of population is the main cause of the evils that afflict society. Are people more happy in a thinly inhabited country? Was the country too populous in the time of the Russian War, when we could with difficulty get enough of soldiers to keep up our forces in the field; but, if this were even conceded, is the remedy to be found in all mankind becoming murderers? With what a shudder do we sometimes hear of shipwrecked mariners, in the frenzy of starvation, agreeing that one of their number should be sacrificed to furnish food to his fellows! But this writer, sitting in his study, in the name of political economy, coolly suggests that one half of mankind should stifle the other half, and from the sordid motive that they may get more comfortably through the world from having fewer competitors in the battle of life. Then, his statements as to the practice of infanticide among the ancients, and their management of their slaves, are mere asumptions, put forward to bolster up his argument without a shadow of authority, and some of them manifestly absurd. The next chapter professes to treat of the remedy for this evil of over-population, the proposed remedy being that families should be limited to three; that marriage should be delayed to about the age of twenty-five; that about eight years should intervene between the births of each child: that this should be carried out at first by a system of permitted association, and in time, as the world becomes sufficiently enlightened, be made general, and enforced by penal regulations, as openly suggested in the following:—

"Thus determined, let us make regulations, such that the possession of children, beyond the due number, be no longer a matter of gain nor even one of impunity.

"We may, at most, place the third child as a *terminus* not quite to be reached and never to be exceeded.

"We must make up the account by delaying the day of procreation, or by refusing to rear the infant inopportunely born.

"It will be made matter of vow and rigid law that all the progeny intervening during the consecrated years be rejected and considered as null.

"We shall be driven, as to a last resource, to deal out with a still more sparing hand the permission for rearing the third child; and to visit transgressions, if we cannot with penal severity, yet with all possible discouragement and restraint."

(*To be continued.*)

A CASE OF PYÆMIA WITH PNEUMOTHORAX. —DEATH BY COMA.

By Richard Barwell, F.R.C.S.,

Surgeon and Lecturer on Anatomy to Charing-Cross Hospital, &c.*

To this case Mr. Barwell was called in consultation with Sir Thomas Watson and Dr. Thistelton Dyer, the latter gentlemen wishing to give up attendance.

Three weeks previously the patient, aged thirty-four, felt, in using some gymnastic exercise, a severe pain in the right axilla. Some days after a swelling appeared at the spot, and at the same time the young man's temper became so morose and aggressive as to be all but unbearable. The swelling soon fluctuated and was punctured; and a few days after, Sir T. Watson being consulted, found extensive pneumothorax on the right side. After a few days more, the left knee became painful, tender, and swollen.

Mr. Barwell found the patient emaciated, of a dusky yellow hue; the abscess in the axilla discharging from a small opening high up; the knee very tender, and containing fluid. He diagnosed the condition as pyæmia. Sir T. Watson pointed out the extent of pneumothorax.

In the progress of the case the axillary abscess, that in the knee and two others, were opened. Under the influence of stimulants, strong food, and tonic medicines the patient's strength improved; but there somewhat suddenly arose a loss of command over the muscles of pronunciation and of the hands, which was followed by coma and death.

The particular interest in the case lies in two points; the singular change of temper, and the mode of death. On the first subject Mr. Barwell stated that he has in many cases of pyæmia which he described, observed similar sudden variation, and submitted that after injury or operation, such should be considered as the first symptom or prodroma of pyæmia. This symptom, it is true, is not always present; but when it occurs, it is pathognomic, and is the very earliest herald of the disease. In two cases he was able to predict the condition three and five days before any secondary abscess appeared.

On the mode of death, he observed that most cases of exhaustive disease (except chest disease) which had been kept alive by high feeding, end in coma from serous effusion. This is generally ushered in by a vagueness of action and a want of distinct will in the movements of the body. If strabismus come on, the coma is close at hand. On the subject of treatment, Mr. Barwell did not wish to enter, although the question of diminishing the stimulus might well be entertained.

MEDICAL EDUCATION IN FRANCE.

By T. Oppert, M.D.

The following is a brief sketch of the system of medical instruction followed at the present time by our neighbours across the Channel:—

There is a minister of public instruction and a council of public instruction, of which he is president. The "conseil supérieur" is composed of 32 members, three being senators, three conseillers d'état, three catholic archbishops or bishops, three belong to other creeds, three members of the "cour de cassation," five of the Institute, eight inspectors-general, two free teachers. One of the inspectors-general has charge of the inspection of the schools of pharmacy, the preparatory schools of medicine, &c., &c.

The council makes the programme of the lectures in the lycées and schools, selects the handbooks, and is consulted as to the whole public education in France. The superior instruction consists of the faculties and of certain Institutes, such as the College de France, the Museum of Natural History, where lectures are given on chemistry, mineralogy, zoology, &c. The French universities consist of *five* faculties, one being that of medicine. There are three medical faculties in France, viz:—Paris, Montpelier and Strasbourg. The university teachers are professors, assistant professors, and "agrégés libres." Paris has 25 ordinary professors, and a great number of supernumerary professors and lecturers. The dean is at the head of the faculty. The professors discuss at their meetings the budget, educational matters, &c. There is a permanent committee of five. Each of the university towns has a superior school of pharmacy, and there are 21 preparatory schools or academies of medicine and pharmacy, viz.:—At Amiens, Angers, Arras, Besançon, Bordeaux, Caën, Clermont-Ferrand, Dijon, Grenoble, Lille, Limoges, Lyon-Marseilles, Nancy, Nantes, Poitiers, Reims, Rennes, Rones, Toulouse, Tours, Chambéry and Algiers are designated to become seats of learning. A military school is connected with the Val de Grâce hospital, and military naval schools with some naval military hospitals, for instance, that of Brest.

---

* A paper read before the Clinical Society, a brief abstract of which appeared in our last.

There are lycées for secondary education, where the pupils are prepared for the examination for the baccalauréat ès sciences. This is in writing and *viva voce*, and corresponds to the English grade of B.A.

Having obtained the certificate the student may get matriculated at a faculty. He follows his studies for four years in accordance with a programme sanctioned by authority, at least if he wishes to become a graduated doctor. There are two classes of medical men in France, the M.D.'s and the "officers de santé." The latter study only three years, their examien is easier* and less expensive, but they have only the right to settle in their own department, and not to undertake certain difficult operations. They do not practice pharmacy, but may occasionally be obliged to dispense their own medicines ; they are, however, dying out.

The higher class of students have to devote two years to the natural sciences, anatomy, physiology, and the theory of medicine and surgery, and two more years to the practice of medicine, surgery and midwifery. Formerly the clinical instruction was postponed to the fourth year, but a recent law of June 16th, 1860, makes it obligatory to devote *two* years to the "stage" of the cliniques.

Externes and Internes.—The externes are hospital-assistants living outside the walls, the internes live in it. Those who wish to become externes must be 18 years old, and inscribed in the faculty, but one inscription is sufficient. The externes are, however, chosen from the pupils, who pass a competitive examination according to merit. They attend the visits of the professors to whom they are alloted, and assist the internes in keeping the books. It is a rule to become externe to a suburban hospital before being admitted to a central one. There are "*feuilles de présence*" kept, wherein they have to inscribe their names to control their regular attendance, but this rule has often been evaded by others putting down the names of their friends. No one is entitled to be externe for more than three years. The "internes" are choosen out of the externes who pass with most credit at the next competitive examinations, they are appointed for two years, generally after the four years of study are over. They then live in the hospital, receiving small salaries and board, and perform the duties of house physicians or surgeons. After the professional visit, they fill up from their notes three books, one for the diet, another for prescriptions, a third one for transference of patients or discharges.

The students pass examinations at the end of each year (*examen de fin d'année.*) The first year's is on physics and chemistry, the second on anatomy and physiology, the third on pathology. Those who distinguish themselves at the examen of the fourth year, generally become internes at once. The examination for the licence is in writing and *viva voce*, includes questioning at the bedside and operations on the dead body. The doctorate is the last and least stringent act of the state examinations. The *thesis* which is read before the representative of the faculty is generally written in French and defended in the same language, and it must be admitted that the first instalments of many excellent scientific works are produced during an academic year. As soon as an interne has obtained the degree of M.D., he has to give up his appointment. They often remain internes for three or four years, and even longer.

After this they often become military surgeons, or poor-law officers, or get other appointments.

The Concours.—Most appointments are obtained by passing competitive examinations. The concours are open for the externes and internes, those foreigners not being excluded who have taken their domicile in France. The Concours date from the year 1802. There are public meetings at the end of the academical year before juries. The members of the juries are nominated by lot; no jury contains more than two members belonging to the same establishment. The concours of the "externate" is confided to the medical affairs of the "bureau central." They take into account the testimonials of the clinical professors. The jury for the election of medical officers of the bureau central are hospital physicians and surgeons, five in number. For a surgical appointment, four of the members are surgeons, and one a physician; for a medical one, four are physicians, and one a surgeon.

The juries for the appointment of hospital physicians includes the leading members of the profession. The nomination is by the minister.

There is no apprenticeship in France as in this country, but a sort of pupilage to a medical practitioner. Pupils who had no medical education assisted practitioners in the country in visiting, went afterwards to the provincial schools of medicine and became "*officiers de santé.*"

There is no particular state examination for medical officers of health. Medical inspectors are appointed by government and they have usually been in office before. There is a class of special inspectors for mineral baths, and for stations in the East.

Hospital Reports.

METROPOLITAN FREE HOSPITAL AND FARRINGDON DISPENSARY.

CASES OF SYPHILIS TREATED WITHOUT MERCURY.

By Charles R. Drysdale, M.D., M.R.C.P., F.R.C.S.,

AND

Robert W. Dunn, Esq., M.R.C.S.,

A part of which was read at the Harveian Society on March 18, 1869.

Case 1.—Charlotte D., aged sixteen, seen by Dr. Drysdale August 2nd, 1863, with roseola, alopecia, and enlarged posterior cervical glands. Had felt a small sore on the vulva a month or so before, which healed of itself. Patient complained of pains in the head. To take the following mixture of chlorate of potash :—℞ Potassœ chloratis, gr. v. ; acidi hydrochlorici diluti, ♏ v. ; aquæ, ℥j. ; ft. haustus ter diesumendus. Under this treatment the disease progressed favourably. She had slight angina, which was treated by a chlorate of potash gargle. By the month of October, 1863, the roseola had disappeared, and she was in very good health. The patient was pregnant at the time.

Case 2.—T. P., a young man, aged twenty, father of Charlotte D.'s child, and subsequently her husband, came soon after the appearance of Charlotte. He was suffering from gonorrhœa and a scaly syphilitic eruption, sore throat, enlarged posterior cervical glands and inguinal glands. Treated by the chlorate of potash mixture, he lost all of his symptoms in about two months. The child with which Charlotte D. was pregnant was born at full time, but only lived seven weeks. It was said to have died of convulsions. Charlotte D., in the year 1865, then in excellent

---

[*] It is, however, public, before the professors in the provinces, who examine them in the elements of medicine, surgery, and pharmacy.

health, brought her second child to be seen by Dr. Drysdale, then five months old. No trace of syphilis was seen on this child, and although it, as well as both of its parents, have been under observation since that date, no further traces of the disease have been remarked in any of them. Such cases are, of course, of themselves sufficient to demonstrate that, contrary to the doctrine of John Hunter and his school, syphilis tends to wear itself out in many constitutions in about a year and a half or two years.

CASE 3.—Mary B., aged thirteen, came under the care of Mr. R. W. Dunn, July 10th, 1865. When first seen, she complained of painful micturition, discharge, and pain in the labia majora, which, on inspection, were observed to be much swollen and enlarged. August 17th. She had a discharging bubo in the left groin; labia much swollen and painful micturition continued, appetite bad; pulse 110; poultices to bubo; ammonia and bark, fomentations to labia. August 24th. Groin still discharging; pulse 110; roseola over the body; bark and nitric acid; poultices to groin. August 31st. Angina and roseola; gargarisina potassae; riss-medicinam. September 7th. Rash paler; throat better. 14th. Psoriasis syphilitica on face, legs, and arms; repeat same medicine. 21st. Cervical glands greatly enlarged; ℞. Tincturae ferri perchlorid, ♏v., aquae, ℥ij, t.d. 26th. Complained of pain in right arm and elbow joint; glands in the neck enlarged and painful; rash fading, repeat. Oct. 25th. Cervical glands still much enlarged, repeat. November 10th. Skin hot and dry; pulse 120; pains in the limbs; ℞ Liquoris ammoniae acetates ℥ij; ammoniae sesqui-carbonates, gr x ij; ætheris chloric ʒij; aquae, ℥vj. ℥j t.d.s November 30th. Much better; only a few spots on face; cervical glandular enlargements nearly gone; to take cod-liver oil and venum ferri. January 5th, 1866. Complained of pains in limbs; a few spots still seen on the face; to have change of air and live well. April, 1866, looked quite well, indeed, the picture of health, and said she had not felt so well for years; a few cervical glands still enlarged. In 1867, she was quite well, with no relapse; and in 1868, continued quite well, without any relapse. In this case the space of one year was sufficient to remove all symptoms in what at first seemed a severe case, and apparently without any probability of a relapse taking place.

CASE 4.—Emma P., aged twenty-four; was seen first by Dr. Drysdale, February 10th, 1864, with ulcers and mucous tubercles on the soft palate, and roseola on the trunk and limbs. This was a very slight case. She was treated by means of gargles of chlorate of potash, and a mixture containing the same ingredients, until the month of April, 1864, when, all symptoms having left her, she came no more for a time. She has repeatedly been seen since that time, but without any symptoms of specific nature being remarked. In January, 1868, she attended with toothache, and at that time was free from all symptoms of syphilis. This patient had been married for some years, but had no children, nor had had any miscarriages.

CASE 5.—Catherine C., aged twenty-four. April 25th, 1864, with stains of *café-au-lait* colour on face and breast, and spots of psoriasis on thighs. Was under treatment for these symptoms for a space of four and a half months. The treatment consisted of gargle and mixture of chlorate of potash. The eruption, though far more tedious than that of Case 4, gradually disappeared. The patient was seen in 1866 in excellent health by Dr. Drysdale, no relapse having occurred.

CASE 6.—John L., aged seventeen; seen first by Mr. Dunn, on the 24th June, 1864, with sore on the penis, very slightly, if at all, indurated; but with multiple enlargement of the inguinal glands. Treated by means of a mixture of chlorate of potash, the sore soon healed up, and he left for a time. September 8th, 1864. He returned, with a scaly syphilitic eruption over the body, face, and extremities. Treated by chlorate of potash mixture. September 29th. Sore throat; ulceration of the tongue. *Repete medicinam*, and use an astringent gargle. October 24th. Discharged without any further symptoms. No relapse since that date.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

(Continued from page 249.)

THE Society held a meeting on Friday evening, March 5th, in the Albert Hall, Royal College of Surgeons,

Mr. PORTER, President of the College, in the chair.

Members present:—B. Wills Richardson, Hon. Sec.; Drs. W. Moore, Morrogh, Willis, Roe, Murdock, T. Stoker, Purcell, Jameson, Henry Gray Croly, R. Fennell, Robinson, Stewart, Brassington, Wharton, Henry Kennedy, J. Hawtrey Benson, Charles Benson, Hon. Sec.; Shannon, White, Buchannon, Mapother, O'Grady, Colles, Jacob, Guinness Beatty, R. Daniel, Hewitt, Churchill, jun., Brady, C. Fleming, Stapleton, Stokes, jun., and Henry Croly.

COMPOUND DISLOCATION OF THE RIGHT ANKLE-JOINT.

Mr. RICHARDSON read the following case, sent to the Society by Dr. NOLAN, of Wicklow:—

On Christmas Eve, 1867, about nine o'clock, a young man, aged twenty-one, driving a bread cart rapidly down a steep hill at Newtown Mount Kennedy, was upset and violently thrown out of the cart, by which he sustained a compound dislocation of the right ankle-joint. He was immediately seen by Dr. McClelland, and brought into his dispensary. Dr. McC. washed a quantity of gutter from the wound and attempted to reduce the dislocation; but, failing to do so, he sent him to Wicklow Infirmary, a distance of eight miles, where he arrived about half-past three in the morning. I saw him immediately, and found the tibia driven down through a transverse slit below, the ankle being laid bare for about four inches, its extremity being on a level with the sole of the foot, which was partially drawn aside, and the end of the fibula broken off. My first consideration was, whether to amputate at once, or try to save the foot, or, if necessary, to have recourse to secondary amputation. Seeing that the patient (though of a very fair complexion and light hair) was a healthy well nourished young man, I decided on the latter course, and applied the pulleys and placed the patient under chloroform; but before making extension I found it necessary, as the bone was *tightly* clasped by the lips of the wound, to make an incision downwards from the under lip, which was turned in, so as to admit of the more easy return of the tibia. I then made considerable traction with the pulleys, but from the contracted state of the gastrocnemii, &c., I was unable to effect reduction without employing more force than I thought safe. I then sawed off about an inch and a quarter of the end of the bone, and at once replaced it without any difficulty, applied a pledget of lint, and laid the limb on the side. The patient fell asleep almost immediately, Dr. McClelland having judiciously given him a large dose of Battley on sending him in.

Next day I found him cheerful, and not complaining much; and, considering the nature of the injury, less inflammation followed than might have been expected, and never extending above the knee. A blush of redness appeared on the outside of the foot, reaching from the ankle to the toes, and which I attributed to the pressure of the bandage used in the pulling of the foot, but which I found afterwards proceeded from the small fragment of the fibula, which was unfortunately overlooked by me in replacing the bone, and which caused a great deal of trouble afterwards, producing a good deal of inflammation and suppuration, requiring opening, and not healing till it was extracted. However, it must be recollected I was alone, with only the assistance of a very intelligent hospital man to attend to the chloroform, &c. I need not enter into a detail of the progress of the case, which must be obvious to the members of the Society. I had, however, to contend with much suppuration and hectic, and at one time was most anxious and dubious of the result; but, thanks to a good constitution, as the event proved, and to abundance of support, the young man was able to leave the hospital on the 17th of May (four months and a half from the accident), with a useful limb, about one inch shorter than the other.

I may mention that this was the *fourth* case of bad compound dislocation of the ankle, attended with much injury to the soft parts, which I had successfully treated without amputation, experience of which influenced me in my decision to give the patient the chance of saving the foot.

Mr. Richardson observed that Dr. Benson received a letter from Dr. Nolan, on Tuesday last, stating that he had seen the young man on Monday, and that the foot is now slightly turned out, the leg being barely an inch shorter than the opposite one. There is also a considerable degree of motion at the instep.

POTTS' FRACTURE.

Mr. H. G. Croly said he wished to bring under the notice of the Society the subject of fracture of the fibula in the vicinity of the ankle-joint, known as Potts' fracture. His object in bringing the matter forward was to elicit discussion as to Dupuytren's apparatus. He also wished to draw particular attention to a plan which he had adopted with the greatest satisfaction—the very simple mode of strapping the splint and the pad on the limb with adhesive plaister, instead of bandage. Mr. Croly then read the following:—

Case 1.—M. M., aged fifty-seven years, was admitted into the female accident ward of the City of Dublin Hospital, under my care. *History.*—She was running down stairs, and turned her right foot violently inwards. She suffered intense pain in the ankle-joint; could not attempt to put her foot under her. *Symptoms on admission.*—Foot everted; ankle-joint increased in width; internal malleolus prominent; *intense pain* produced by making pressure over the lower part of the fibula, which was found to be fractured about two and a half inches above the malleolar tip.

Reduction effected in following manner:—Leg flexed upon the thigh and the thigh upon the abdomen, to relax the muscles; knee-joint grasped by an assistant to keep the limb in the flexed position; foot was grasped and inverted, and the tibia pressed outwards on the astragulus. Dupuytren's apparatus applied and fixed by *means of soap plaster* in the following manner:—The conical pad was placed on the side of the limb, its base extending as far as the internal malleolus; the splint was then adjusted. Broad strips of soap plaster were applied evenly around the leg, for about a hand's breadth, below the knee-joint to fix the upper end of the appliance. The foot was then approximated to the end of the splint, and retained in the inverted position by means of strips of plaister applied in a figure-of-eight form, embracing alternately the dorsum of the foot, the end of the splint, and the heel; the limb was then flexed and placed upon a pillow, lying on its fibular side. The apparatus was kept on for a month, and was then removed, and the joint supported by strapping with plaster covered with a woollen bandage. The patient was discharged from hospital in nine weeks from the date of admission, with complete union of the fracture, and without deformity.

Case 2.—L. McE., aged twenty-seven years, a labourer, was admitted into the male accident ward. *History.*—In jumping off a height he turned his foot under him, and suffered great pain. Does not know whether his foot turned *inwards* or *outwards*. *Symptoms.*—Foot *slightly everted;* inner malleolus projecting; considerable tension produced by effusion into the ankle-joint; ecchymosis of leg and over the base of the internal lateral ligament; great suffering caused by pressure applied over the lower end of the fibula, which was fractured about one inch and a half above the tip of the malleolus. Reduction effected as in Case 1, and Dupuytren's apparatus applied with plaister; cold evaporating lotion to the joint. Patient discharged in six weeks, the foot and ankle being previously well-strapped and bandaged.

Case 3.—P. M., engine-driver of the train to which the accident occurred near Bray Head, was admitted into the hospital suffering from fracture of the fibula, two inches above the end of bone. Patient said he jumped off the engine, and fell a considerable height, and turned his right foot under him. On admission, there was very great effusion into the joint, and extreme tenderness over the fibula.

Dupuytren's apparatus applied as in previous cases; iced lotion to joint. Patient discharged in one month, with starched bandage applied. He was a considerable time in recovering the free use of the leg, as he was a very heavy man.

Case 4.—P. N., aged twenty-three years, a coal porter, had been drinking, and turned his right foot under him; suffered much pain; admitted almost immediately into the hospital.

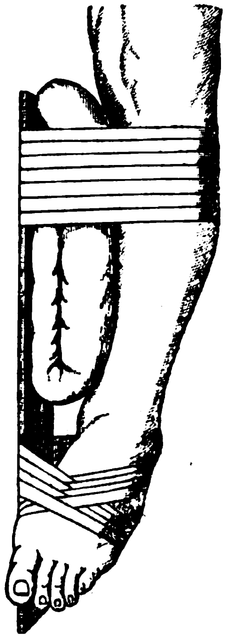
Symptoms.—Inability to walk; ankle-joint swollen; severe pain on pressure over the lower end of the fibula, two inches above the end of the bone; foot *slightly* everted; yielding of fragments on pressure being applied over seat of fracture; internal ankle prominent, and integument tense; effusion into joint. Dupuytren's apparatus applied as in preceding cases. Patient discharged in a month; starched bandage applied.

Case 5.—J. D., an in-door servant, slipped coming down stairs, and turned his left foot under him; felt something snap. *Symptoms.*—Inability to walk; pain in lower end of fibula; effusion into joint.

Case 6.—Mr. ——, aged thirty-eight years, residing near the hospital, slipped off the foot-path one dark night, and turned his left foot violently under him; he fainted from the pain, and was carried by his own request to the hospital.

Symptoms.—Left foot *everted;* a depression was observed about two inches and a half above the end of the external malleolus. The internal ankle was very prominent, and threatened to burst through the integument, which was tightly stretched over it; effusion into the joint and entire leg.

Patient complained of most excruciating pain. Reduction effected as in other cases, and Dupuytren's apparatus applied, from which the accompanying drawing was taken. Cold lotions were applied; large bullæ formed along the leg. Patient discharged in a month.



Case 7.—M. T., a female, aged sixty years, turned her left foot inwards; fibula fractured two inches and a half above malleolar tip; marked eversion of foot. Dupuytren's apparatus applied as in previous cases; *never required a second dressing.* Patient discharged in a month cured.

Case 8.—M. M., a man, aged thirty-four years, turned his right foot violently; fibula fractured one inch and a half above tip of malleolus. Dupuytren's apparatus applied with plaister. Result satisfactory.

Fracture of fibula two inches and a half above end of malleolus, with fracture of lower end of tibia, and displacement backwards of the foot.

Case 9.—J. F., aged thirty years, a policeman, was lifting a heavy cask of porter, and his left foot turned under him; he felt his ankle snap, and suffered much pain in the part; admitted at once into hospital.

Symptoms.—Left foot *slightly* everted and displaced backwards; enormous effusion into the ankle-joint; leg swollen. Internal malleolus remains attached to the astragulus; lower end of upper fragment protruding forwards on the neck of the astragulus; tendo-Achilles arched; heel unnaturally prominent.

Treatment.—Foot flexed upon the leg, the leg upon the thigh, and the thigh upon the abdomen. Reduction was then easily effected by pressing the tibia backwards, and inverting the foot. Dupuytren's apparatus was applied to the *back* of the limb in the following manner:—The wedge end of the pad was placed in the hollow above the heel, the splint underneath it; broad straps of plaister were then applied around the limb, a hand's breadth below the knee, and also above the ankle-joint (a compress of lint being placed on the front of the tibia low down to bear off the pressure of the plaister). The limb was then placed in a fracture-box, carefully padded and elevated, so as to keep the limb flexed.

Fracture of the fibula, two inches and a half above the ankle-joint, with rupture of the deltoid ligament; partial luxation of the tibia forwards and foot backwards.

Case 10.—E. H., a female, aged forty-six years, was walking down the street, her foot slipped, and she cried out that her leg was broken, as she felt a snap; she was admitted into the hospital. *Symptoms.*—Foot foreshortened; fibula fractured two inches above its malleolar end; no *eversion* or *inversion* of the foot; the malleolar end of the tibia was felt and seen projecting on the neck of the astragulus. Reduction was effected and apparatus applied as in Case 9. Patient recovered perfect use of joint.

Mr. Croly continued to say that, during the two years and a half he had resided as House Surgeon in the City of Dublin Hospital, he had seen all the cases of Potts' fracture immediately on their entering into the house. He believed the marked eversion of the foot as pictured by Pott was the exception, and not the rule. He thought the fracture was generally not so high up as pictured by Pott, and that the deltoid ligament was frequently ruptured. He had, however, seen instances in which the foot presented the exact appearance represented by Pott. Generally his experience was, that the fracture was closer to the ankle-joint, the deltoid ligament ruptured, a blue line visible corresponding to the torn ligament, and there was extreme tenderness over the seat of the fracture of the fibula. He thought the rule that guided most surgeons was, if there was extreme tenderness in the lower end of the fibula with crepitus, to treat the injury as a fracture. He thought it was an exception to get crepitus in a fracture of the lower end of the fibula. In the other case of fracture to which Dupuytren called attention, and on which Mr. Adams had written so admirably, Dupuytren recommended that a pad should be laid behind the heel, and he did not say anything of putting the limb into a box splint. He should like to hear the opinions of the members of the Society on these points:—The distance of the fracture from the ankle-joint, the adaptability of Dupuytren's apparatus, and the use of the sticking plaister, instead of the bandage, which had been very successful in his hands. It had been remarked that if this splint was kept on too long it caused eversion of the limb, and it had been suggested to change it to the outside of the limb to prevent the deformity. He had never seen any bad result from Dupuytren's apparatus when properly applied.

The **Chairman** observed that Mr. Croly's paper was an interesting one, and the adoption of sticking plaister instead of the bandage was its essence.

Mr. **Stapleton** said he had always been in the habit of putting up children's fractured thighs with sticking plaister, and he found it to answer very well. As to Dupuytren's apparatus, everyone of large experience knew that it was about one of the worst apparatus as regards the comfort of the patient and convenience of the surgeon, because it was always slipping. For several years he had not tried that splint, but always used the box, with which his cases had a great deal of comfort. Dupuytren's apparatus had been modified by English surgeons, and notched to keep it in its place; but the simple apparatus itself was objectionable on the ground he had mentioned. As to the rupture of the deltoid ligament, it was exceedingly rare; so much so, that in his long experience he had never seen rupture of the deltoid ligament without a portion of the internal malleolus being carried away; and, in compound fracture, it was frequently demonstrated that the tip of the internal malleolus was more frequently broken than the rupture of the ligament alone.

Mr. **White** said he had opportunities in Jervis street Hospital, during the last couple of years, of seeing a number of these cases immediately after the occurrence of the injury, and in all of them there was proof that the lower end of the internal malleolus was torn off with the ligament. As to the situation of the injury, he believed that the fracture of the fibula was rather higher up than Mr. Croly had described it to be. It was in the space where the latter fracture occurred, between two and three inches above the ankle, that the displacement was greatest. No doubt, however, that fracture of the fibula occurred in every situation, from an inch or less up to three inches above the ankle. He believed that Dupuytren's apparatus was generally abandoned at the present day. The box splint was far more successful, and indeed the success which he had seen follow the use of it was most satisfactory.

Mr. **William Stokes** said he could not agree with what Mr. Stapleton had said of the difficulty of keeping Dupuytren's splint in its place. His experience was extremely small compared to that of Mr. Stapleton, but he had endeavoured to carry out the treatment of these accidents as described by Dupuytren, and had never found extreme difficulty in keeping on the splint. At the same time, the treatment by the box splint was a good one, and was one adopted by his esteemed and honoured friend, the late Mr. Hutton, in the Richmond Hospital. He had not tried the mode of keeping the splint in its place by sticking plaister. In cases where there was a fracture of the fibula with fracture of the lower end of the tibia, and a tendency to displacement forward, it was extremely difficult to keep the bones in their places. He had a case of that kind, but until he had followed the plan recommended by Dupuytren of putting the splint along the posterior surface of the limb, that he was enabled to keep the fragments in their places, and the result was an excellent one.

Mr. **Wharton** could fully corroborate what Mr. Stokes had said. He had never found the extreme difficulty spoken of by Mr. Stapleton in using the apparatus of Dupuytren. It appeared to him Mr. Croly's drawing was not well delineated, for it represented the foot as too much extended. He mentioned this because Mr. Croly said if the apparatus was kept on too long there was a fear of talipes varus taking place. Now, if the foot were kept up, as represented in Mr. Croly's drawing, he thought talipes varus a very likely consequence.

Dr. **Grimshaw** said that when he was a student of Steevens' Hospital he always used sticking plaister, by the direction of Mr. Cusack, in attaching Dupuytren's splints. He indeed thought that he also put up with sticking plaister most of the ordinary fractures which came into the hospital.

Dr. **Henry Kennedy** thought the seat of the fracture of the fibula would be affected by the height of the patient. If a man were five feet six inches the fracture would be nearer the malleolus than if he were six feet.

Mr. **Fleming** recollected the case alluded to by Mr. Stokes. He thought the position in which they placed the individual in the first instance was on his back, and in which position he had treated these cases of fracture of the fibula. He accidentally saw the man a fortnight ago, and he certainly seemed to have made a better recovery than could have been anticipated from the nature of the injury, although at present he laboured under a difficulty of moving the joint, and there was a good deal of displacement of the anterior portion of the fracture. The case was a very complicated one, very difficult to deal with, and the patient not very tolerant of treatment. As regards Dupuytren's apparatus, all surgeons were aware that there was a modification of it suggested by Mr. Fergusson which resembled much in its construction the ordinary Liston splint for fracture of the femur. In treating Potts' fracture, he had used the apparatus delineated by Dupuytren, and he must acknowledge there was often extreme difficulty in keeping the limb in a position that would secure the perfect adaptation of the bones. In cases where the tibia was thrown forward he derived great assistance from the application of a compress, but there was great difficulty in compressing it with a box apparatus—he alluded to the apparatus where the box splint was formed with hinged side splints. He attached great importance to the position in which the foot was placed. Further injury was likely to arise from inattention to this point.

Mr. **Stapleton** said the box splint used in Jervis street Hospital was one with a back board, having hinged sides, and also having a foot board. Whenever there was displacement forward, all the surgeon had to do was to place a pad in front and keep it in its place with a buckle bandage. In treating fractures, the worst thing possible were bandages. If the surgeon could keep the limb in a box splint without constricting it by a bandage, he would gain a great deal. By putting a pad here and there, and securing the limb in a proper place, it was fixed, and not at all constricted.

Mr. **B. Wills Richardson** said there was often in these cases difficulty in making an exact diagnosis as to the exact seat of the fracture of the fibula, for if the bone is broken obliquely, the everted foot may tilt the lower fragment upwards, and thereby lead to overlapping, the most tender spot corresponding to the end of whichever fragment is nearest the skin. Thus, for instance, should the lower end of the upper fragment overlap the upper end of the lower fragment, the surgeon might be erroneously induced to think the fracture nearer the malleolus than it is in reality.

The **Chairman** observed that in the last number of the

Dublin Journal there is a very interesting description of a splint by Mr. Swan.

Mr. Croly, in reply, said he did not profess to be the first who used sticking plaister; he only meant to say that he had found the sticking plaister an excellent mode of treatment. No matter how well the bandage was applied, he always found it slipping, and that suggested the use of the sticking plaister, which he found to answer the required purpose. With regard to the rupture of the deltoid ligament, he thought they need not pass Mr. Pott. He said it was frequently torn through. Mr. White said that the end of the malleolus was generally broken off, instead of the ligament being ruptured; but it so happened that in the cases which he (Mr. Croly) had seen such was not the case. With regard to the drawing, to which Mr. Wharton had called attention, the peculiar appearance it presented was owing to the point of view from which it had been taken. He found that in "Miller's Surgery," a very good book in many respects, Dupuytren's splint was described as a forked splint with a bandage running from the knee down. When such an error could be made in such a work he thought he was justified in bringing the matter before the Society. He had treated ten or twelve cases with this apparatus, and with the sticking plaister, as described; and he was so well satisfied with the result that he would continue the practice.

SIMULTANEOUS DISLOCATION OF BOTH PATELLÆ OUTWARDS.

Dr. Mapother said that his former pupil, Assistant-Surgeon Conry, of H.M.S. "Doris," sent to him the description of a case of simultaneous dislocation of both patellæ, which he thought worthy of record. A midshipman, aged seventeen, while shooting in Jamaica, aimed at a bird flying directly over his head, and in doing so, lowered his body by flexing both knees considerably. The instant he fired he fell with both patellæ dislocated outwards, and when raised both bones were replaced by pressure, the knees being extended. This occurred nearly two years ago, and since then the right patella has been twice thrown out, but the left has retained its normal place. The dislocation outwards is rendered likely by the fact that an angle inwards is formed by the rectus muscle with its tendon, the ligament of the patella; and is for the same reason more apt to occur in persons whose knees approach each other more closely than usual. It is, however, prevented by the greater projection of the outer condyle. In such cases the best mode of reduction seems to be, to place the heel on the surgeon's shoulder, the patient being horizontal and the bone can be then readily pressed inwards. A patient of mine has often expressed to me his fears that in going upstairs "his knees would give way;" and this is just the position in which a dislocation outwards of the patella would be probable. When the foot is landed on one step the knee is fixed, but on raising the next it is extended, and if this extension be performed too vigorously or suddenly, the quadriceps may jerk the patella outwards, notwithstanding the projection of the outer condyle of the femur.

The meeting adjourned until the 19th March.

DUBLIN PATHOLOGICAL SOCIETY.

February 20.

Mr. Barton exhibited a

SPECIMEN OF CARIES OF THE BONES OF THE FOOT.

The young women who was the subject of this disease was of a remarkably strumous disposition. She suffered from lupus of the nose, and had other strumous symptoms. The part of the foot affected was originally the outside of the os calcis. She had been submitted to various forms of treatment, and when she came under his care, last October, it appeared to him that the disease was limited to the os calcis, and that therefore he could perform an operation for the removal of the diseased bone without sacrificing the foot. The operation checked the further progess of the disease in the os calcis, but after the lapse of some time, further symptoms occurred, leaving the inference unavoidable, that ther bones were engaged. It became necessary, therefore, to amputate the foot, which was done after the modified method of Mr. Syme. Cutting off the bones a little above the ankle-joint, and getting the covering from the inner and lower part of the heel, the astragulus was found in the first stage of strumous disease. It was yellowish, vascular, and soft. The portion of the bone where the first operation was performed presented some interesting pathological changes at the bottom of the cavity formed by the gauge. Caries existed to a certain extent, but a further change had taken place. The bone surrounding this was harder than natural; there was no caries, beyond this indurated loose tissue. The extension of the disease was due to the original cause which predisposed this patient to this form of disease, and which still existing, disposed her to farther disease in the bone rather than the extension of the disease from the point in which it first appeared. The case was one of interest from the well marked hardening which existed round the calcis, whilst the astragulus itself was the seat of the disease which had rendered necessary the amputation of the foot.

ENCEPHALOID CANCER OF THE LIVER—ATROPHY OF THE HEART.

Dr. Cryan said that James W———, a wool-packer, aged 52, was admitted into St. Vincent's Hospital, under his care, on the 19th December, 1868. For the past six or eight years, the patient had been in the habit of drinking from two to three quarts of porter daily, but he usually enjoyed good health up to seven months before the period of his admission into hospital; he then began to complain of want of appetite, occasional nausea, and gradual loss of flesh and strength. On admission, he looked pale and anæmic, and much depressed in spirits; he was greatly emaciated, and complained of loss of appetite, nausea, flatulence, and extreme debility; there was slight tenderness over the stomach, but no pain; he had never discharged blood from the stomach, or bowels, nor had he been infected with syphilis, or suffering from caries of bone; the liver could be felt projecting fully an inch and a half below the right costal margin; it was hard, and smooth, and slightly tender on palpation; the hepatic dulness, in the right mammary line, measured 6¼ inches; there was no evidence of splenic enlargement; there was a small amount of effusion into the peritoneum, the girth of the abdomen, at the umbilicus, measured 34 inches, the superficial views of the abdomen were not enlarged. The urine was scanty, sp. g. 1032, acid, dark like porter, and threw down a copious deposit of lithates; it contained some bile pigment, but no bile-acids, and no albumen; tongue moist and covered with a thin fur; bowels free, motions contained bile, and were not offensive. The respiratory signs were normal; the impulse of the heart was very weak, the first sound was short and clear, resembling the second sound in these characters, the area of cardiac dulness somewhat diminished; pulse at wrist was small, weak, but regular, 80 in the minute; skin hot and dry but neither it or the conjunctivæ presented any jaundiced tinge.

Dr. Cryan said, that when he first saw the case he had some little doubt as to the nature of the hepatic enlargement—the intemperate habits of the patient, the firm resistant though smooth liver felt close below the costal arch, the dyspeptic symptoms, and the ascitis seemed to suggest that it might be due to cirrhosis in its *first* stage, in which, before the process of contraction sets in, we occasionally find the organ slightly enlarged, and firm and smooth; but against this view were the absence of splenic tumour, of any enlargement of the superficial abdominal veins, or of gastric or intestinal hæmmorrhage, and the marked cachexia, and rather rapid course of the disease: again, the smooth painless and firm enlargement of the organ might arise from waxey liver, but in waxey enlargement the progress of the disease is slow, and there is usually enlargement of the spleen, albuminuria with marked increase in the quantity of urine, and a history of constitutional syphilis, or chronic disease of the bones,—all of which were absent in the case before us; he (Dr. C.,) therefore, thought it probable that, notwithstanding the absence of pain, and the inability to feel any tubera projecting from its surface, the enlargement was due to cancer of the liver. On the 30th December, ten days after the patient's admission into hospital, two or three round firm nodules, each about the size of a marble, were distinctly felt on the anterior surface of the left lobe, the entire liver had, meantime, increased much in size, the emaciation continued to progress, the patient passed sleepless nights—though he never suffered from pain—and the cachexion was more pronounced, so that there could no longer be any doubt as to the cancerous nature of the disease. On the 1st of January, 1869, he became slightly jaundiced; the stools still contained abundance of bile, the jaundice persisted till his death.

On the 29th January, ten days before the patient's death, the right lower extremity became anasarcous, the swelling extended gradually up to the crest of the ilium. There was no tenderness over the veins of the limb, nor did the patient complain of pain, the skin was pale, and the temperature was a few degrees below the normal standard; pulsation could be felt in the dorsal artery of the foot. From this date until his death, on the 8th February, the œdema of the lower limb slowly increased.

Post-mortem examination, fourteen hours after death, exhibited the following appearances:—The liver was enlarged, it weighed 5lbs. 4oz., and was thickly studded on both surfaces, and throughout its interior, with round whitish tubercles of brain-like consistence, varying in size from a pea to a small chestnut; but few of these tubercles presented the usual umbillicated appearance on the free surface, or showed any central softening; the hepatic substance surrounding them was for the most part of a yellowish brown colour, but at some points, where the tubera were of large size, the liver substance was of a greenish hue, and seemed condensed by their pressure; three or four large nodules projected from the anterior surface of the left lobe of the liver, close to its thin edge; on a microscopic examination of the creamy juice obtained by scraping a section of the tubercles, it was found to be made up of large nucleated cells, round, and fusiform, ranging from one-hundredth to one thousandth of an inch in diameter, with a nucleus, about one-third the size of the cell, surrounded with fine granular matter, which resisted the action of ether, and was not of a fatty nature; the hepatic lobules intervening between the cancerous tubercles were not infiltrated with cancer, but many of the hepatic cells were loaded with oil, and some few looked small and withered; the hepatic cells in the centre of each lobule were nearly filled with bile-pigment.

The glands in the transverse fissure of the liver were infiltrated with cancer, and formed a tumour as large as a hen's egg, which embraced the common bile duct and the blood-vessels; his (Dr. C.'s) friend Dr. Nixon carefully dissected the trunk and primary branches of the vena porta, hepatic artery, and bile ducts, and found them all to be quite pervious, and free from coagula, and but little altered in size; the cystic duct, however, was much compressed and superficially ulcerated at its origin from the gall bladder, by one of these cancerous glands; the gall bladder was contracted, its coats were thickened, and it contained about half an ounce of dark green bile. The head of the pancreas was slightly infiltrated with cancer, and was hard and of a greenish yellow colour, but the opening of the common bile duct into the duodenum was quite pervious. The right common iliac vein was much compressed by a large cancerous gland, its cavity did not contain any coagula or cancerous masses; the iliac arteries were quite free and pervious. The stomach and intestines were normal; the spleen was small, weighing 4½ oz., its fibrous coat thickened, the parenchyma firm, and of a dark brown colour. Iodine and sulphuric did not develope any so-called amyloid reaction when applied to the tissue of the spleen, liver, or kidneys—the latter were hard, smooth, and congested, and weighed only 3¼ oz. each; the heart was small, weighing only 5½ oz., its muscular tissue was pale, and softer than natural, but there was no fatty degeneration; the cardiac valves and orifices were healthy; the lungs were much congested, but in other respects quite normal.

Dr. Cryan stated that it was worthy of notice that in this case there was complete absence of all pain, thus affording a further illustration of the clinical fact that encephaloid of the liver is often a painless disease, and in marked contrast, in that respect, with true scirrhus of the organ, which is comparatively rare, but an interesting case of which has been recorded by Dr Stokes (proceedings of Pathological Society, New Series, Vol. 3. p. 170) in which "the principal symptoms were jaundice *and intolerable and persistent pain*." The great atrophy of the heart in the present case was also of interest—as well as the cause of obstruction to the circulation in the right common iliac vein revealed after death, and explaining the œdema of the right lower extremity noticed during the last ten days of the patient's life. In a case of cancer of the liver recorded by Dr. Gordon (Proceedings of Pathological Society, New Series, Vol. 2. p. 160) the patient *suddenly* complained of severe pain in the left lower extremety, rapidly followed by great swelling, and a fall of several degrees in its temperature, with absence of any tenderness on pressure over the large veins; Dr. Gordon diagnosed that the main artery of the limb had been suddenly occluded, and *post-mortem* examination verified the diagnosis, showing, "that the interruption to the circulation was caused by the left common iliac artery being completely obstructed by a mass of semi-diffluent cancerous matter."

WEDNESDAY, MARCH 31, 1869.

HOSPITAL REFORM.—THE ACADEMY OF MEDICINE.

The debate of Wednesday last, in the Metropolitan Branch of the British Medical Association, has cleared up many doubtful points on the question of medical reform. The first point treated of was as to the advantage or not of admitting patients to hospital without the necessity of Governors' letters being obtained. This part of the debate was opened by Dr. C. Drysdale, who, in advocating the adoption of this system in opposition to the system by Governors' letters, gave as reasons for it, his own experience that, at the Metropolitan Free Hospital, the class of patients admitted were all evidently very poor and unable to pay for medical advice. Many persons, he thought, with means were deterred from coming to hospitals when admission was free, because they did not like to mix and beg for admission with a crowd of their poorer neighbours; and, having more time to themselves, the better class of patients obtained Governors' letters to some of the other hospitals, and thus the struggling London medical man lost some of his patients. About 100 new cases of out-patients were daily admitted to that Hospital, and he thought it would be a good thing, in addition to this, if there were some plan suggested to prevent persons of any means from coming to take advantage of the charities in London and elsewhere to the detriment of the medical profession. Mr. Teevan, in a generous speech, Mr. Coulson, Mr. F. Mason, Dr. Oppert, and several other gentlemen were in favour of this open admission of patients. Dr. Stewart and Mr. Christopher Heath, however, made objections to it, the latter observing that this system would require the establishment of one or two central offices for the selection of patients for admission into hospitals. Many arguments, however, were brought forward as to the bad working of the system by means of Governors' letters, and, on the whole, it may be admitted that there is great probability of the free admission of poor patients becoming, as it has long been in France and throughout the Continent, the usual mode of admission to all charities. In the Bureau Central, at Paris, as all well know, the applicant for hospital treatment presents himself, unless in cases of urgency, before able physicians and surgeons, and is at once rejected if his case does not require in-door treatment, or admitted at once into some hospital if a fit case. Two such central offices might be required, *perhaps*, in gigantic London; and all our large hospitals should be affiliated. We are convinced that subscribers would be often delighted to get rid of the annoyance of being applied to for letters, and, indeed, it was conclusively shown that it was already often remarked by the Governors, "I will gladly subscribe to your charity, but don't send me any letters."

The second heading of the debate was that of medical specialities—a subject full of interest, especially at the present time in London, where, as remarked by a famous Parisian physician, there is scarcely any person in the medical ranks who is not a specialist—that is, among hospital physicians and surgeons. Dr. Beigel, indeed, in a speech of great force, and which was well received, explained this very well when he remarked that he was not astonished that there existed many specialities in London, and only wondered there were so *few* of them. Because, said he, when a young medical man of promise wishes to devote himself to teaching some part of the medical art in Germany, he has by no means a difficult task to perform. In such a case he goes to the university and announces his desire to give a course of lectures on ophthalmology, or on the laryngoscope, or on syphilis, or any other subject he pleases, and the university immediately grants him a lecture-room within its walls; and then, if he becomes popular, he is likely to rise into notice as a teacher in a short time. In London no such facilities exist, and hence the man who has a taste for practical medicine has but one resource—namely, to take up a special hospital. The arguments against the expense of special hospitals were met ably by Mr. Coulson, Mr. Teevan, and Dr. Morell Mackenzie, by the observation that they were found to be cheaper per patient, per bed, than the large hospitals; and there does appear to be another telling argument in the facts recently alluded to by Sir James Simpson, as to the greater mortality of large than of small hospitals. Mr. C. Heath and Mr. Hart a little invalidated the force of the argument as to comparative expense when they mentioned that, in the large hospitals, cases requiring more expensive apparatus were treated, whose treatment, of course, required more outlay than those suffering from diseases of the eye, the throat, or the urethra. For our own part, we must say we think that Sir James Simpson's arguments against large hospitals are unanswerable, and we do not think that perhaps any hospital with above sixty beds should ever again be built. It is impossible to get rid of miasmata and pyæmia in large hospitals, and hence we are not at all averse to seeing specialities multiply as much as possible until the subject is better understood, especially as there can be no doubt that students can learn much more by attending for a few weeks at each speciality than they could by passing a far longer time in wards of a general hospital. Who is there, for instance, who has passed any time at the Moorfields' Ophthalmic Hospital in London, or at the St. Louis or the Hôpital du Midi of Paris, without learning infinitely more about diseases of the skin, &c., than he ever could have hoped to do in the same time at St. Bartholomew's or the Hotel Dieu?

A topic which has not as yet been introduced into the debate is that of provident dispensaries. Doubtless this form of medical relief is the one which is destined in the future to take, in a great measure, the place of our present medical charities. Self-help, we all know, is the only way to anything like a good and wholesome life, and the notion of accepting charity is one which ought always to be painful to every member of society who is not totally unable to render some reciprocal benefit for whatever favour he receives. London, as usual, is behind the rest of England in providing for such co-operative medical or other assistance as provident dispensaries or co-operative stores. But it is a sign of the times that one or two such dispensaries are budding forth even in this vast metropolis. For example, the St. Marylebone Provident Dispensary has about 3,000 members, who contributed in the year 1867 no less than £222 to the institution, and in the same year the medical men connected with the institution received £40 each for their valuable services, instead of giving these services gratuitously, as is done in the majority of our London hospitals and dispensaries by gentlemen who can ill afford to do this. The drug bill of that year was only £77, and the rent £30, while the dispenser's salary, £73, and the collector's poundage, £4, and secretary's salary, £30, formed the chief expenses of the establishment. When it is known that one of the medical officers is Mr. William Sedgwick, a gentleman of the most distinguished acquirements in medical science, and whose works on hereditary disease and on cholera have been as highly appreciated by the medical profession, we need hardly say that it is time that the rest of the profession imitated the example of such able men, and turned most of the medical charities into provident dispensaries.

The great mistake in London, as was pointed out by several of the speakers on Wednesday last, lies in the multiplicity of small medical schools. There is no need of more than one, or at the most two schools, which, of course, would then secure the most able men of the day for professors, as the Academy of Medicine in Paris does at present, and which has rendered its professors so eminent; and this leads us to refer to the cheering announcement recently made by Mr. Solly, from the President's Chair of the Royal Medical and Chirurgical Society of London, that a committee of that society has reported in favour of the amalgamation of all our distracted societies into one whole, under the name of the Academy of Medicine of London. We know of no step more likely to advance the interests of medical science and of the practitioner of medicine than this. And we believe, that this will be but the beginning of further great and vital changes, such as the establishment of one government degree, which should be taken per force before any other body were allowed to grant any degree in medicine or surgery. When this was once accomplished, we might look forward to an united profession of medicine; or, at any rate, to a satisfactory termination of the invidious distinctions which have so long subsisted between the general practitioner and the physician, or hospital surgeon. There should be no grades in medicine, which has all the element of a republic; and the only avenue to rising to high posts in our ranks, *of course*, should be the free competitive examinations, which have made the Parisian School what it is. The Academy of Medicine once established, there could be but little difficulty in choosing amidst its ranks a certain number of distinguished professors who might lecture to the whole of the students attending hospitals in London, and grant them certificates for attendance on lectures, if this were necessary. In addition to this, each hospital might have its practical school for lectures on auscultation, bandages, &c., &c. Hospitals would then be places for treating the sick, for the study of clinical medicine, and clinical lectures, not partly for extra-practical scientific pursuits, as at present. The existence, too, of extra-academical lectures ought to be encouraged, by the permission given to all members of the profession desiring it to give short courses on different practical subjects, as is done at the Ecole Pratique at Paris, where we have heard the illustrious Chassaignac and many world-renowned specialists lecture to admiring and enthusiastic listeners.

There never was a time in which there seemed more desire to reform our medical corporations than the present. And the lively character of the debate of the other evening shows how deeply the importance of the changes contemplated is felt by the younger members of the profession. Indeed, it is complained by many of them that the present system of admission to hospitals is completely pauperizing the medical profession; and that it is becoming very difficult indeed for a young surgeon or physician to live by the exercise of his profession, whilst the general practitioner is no less, and most justly, indignant at the number of patients withdrawn from his care by charitable institutions, which afford both the most skilled advice added to the enjoyment of medicine and nursing without any trouble or expense to the applicant. In bringing forward this question, then, we may truly say that Mr. Ernest Hart has done some really admirable work. His advocacy of the extension of the Contagious Disease Act to the general population, we are by no means so much in favour of; and there are certainly some important blemishes in the system of parochial hospitals; but in this last discussion, inaugurated by him, we have none of the principles of individual liberty infringed, and we heartily wish all success to the committee appointed by him for the examination of the best means for effecting hospital reform.

◆

PAUPERISM IN LONDON.

Mr. Purdy's Return, showing the valuation, area, population, and pauperism of London, furnishes us with some instructive statistics. First of all, we find that the rateable value of the metropolitan unions has an aggregate amount of £16,818,768. According to the last report of the Poor-law Commissioners the net annual value of property rated for the whole of Ireland is £13,045,725; total relief granted to the poor of the metropolitan unions, £1,316,089; total of poor relief and medical charities Ireland, £794,894. The total "average" of pauperism in the metropolitan districts (London) was as high as 145,369 souls. Besides all this, it has been estimated that 1,800,000 persons (not including the pauper sick) received relief during the year in the London hospitals; and, finally, the Bishop of London sums up with the following statement:—"It seems that there now exists in the metropolis more than a thousand associations for charitable purposes, administering annually about £4,000,000, this being an average of £4,000 for each society." This is besides and beyond the enormous expenditure under the Poor-law. Notwithstanding all this expenditure, it is but a few weeks since we heard of a woman dying of starvation within this district; and the spread of want, misery, pauperism, and crime in London is daily impressed upon us. There must be extravagance and waste somewhere. Large sums are consumed in expensive and superfluous machinery; large sums are lavished in the support and encouragement of systematic and organised imposture, while deserving poverty is not relieved. Nobody can doubt that if the Poor-law on the one hand and the various charities on the other were properly administered, this vast sum, nearly five and a half millions a year, would be more than sufficient to meet every exigency, and that want and suffering ought to disappear from the metropolis. Nor are the members of the medical profession entirely free from all blame in the existence of this state of things. There is that little item of 1,800,000 persons who received gratuitous assistance from the London hospitals. What is Dr. Stewart's opinion on this subject? At the late meeting for the discussion on hospital administration, he said,—"The profession are responsible to the public in this matter, which is very far from being merely professional." In a pamphlet on "Medical Charities as they are and as they ought to be," he had pointed out that these institutions were great breeders of pauperism. He used to notice, in dispensary practice especially, that patients at their first application would say "that they did not like to come to get relief for nothing, but had at last been compelled to do so." At their next application there was no such compunction. The next time, if there was any pinch in circumstances, the patient went to the workhouse, of which not a few became habitual frequenters whenever any difficulty occurred. Thus in many instances the free dispensary was the first downward step to pauperism.

SCOTLAND.

EDINBURGH.

ROYAL INFIRMARY.

At length the contributors to this Institution have come to a decision on the question as to where the new building should be erected. After a long discussion at a meeting held in Queen street Hall, at which the reports of the committee were presented, Professor Syme's motion—"That the new Infirmary shall afford accommodation for surgical as well as medical patients, and that it shall be built on the grounds of George Watson's Hospital"—was carried by a majority of 94. Also, on the motion of Sir J. Simpson, the managers were directed to consider the propriety of establishing a Maternity Hospital in connection with the new Infirmary. The managers, at a subsequent meeting, considered that no obstruction should be thrown in the way of carrying out the motion of Professor Syme.

It seems that there is a legal question connected with these proceedings. Those only who had contributed £5 and upwards to the funds of the Infirmary were allowed to vote. Those who had not done so, though they had contributed to the new building fund, it was considered could not vote. There is some doubt whether this ruling is correct; but either way, it will be right that those who have been excluded from voting should be consulted to know what is their opinion of the motion of Professor Syme—whether they agree that the money subscribed by them should be devoted to that purpose; and, if not, that it should be refunded to them. We should think, however, that few will be found who object to the decision of the contributors, and wish to withdraw the money they have given.

UNIVERSITY—CHAIR OF CHEMISTRY.

THE *Scotsman* says:—"We are requested to state that the curators will meet on Wednesday, 14th proximo, to elect a Professor of Chemistry, in room of Dr. Lyon Playfair, and that applications of intending candidates, and relative documents, fall to be lodged with the secretary on or before Saturday the 3rd proximo."

DISTRICT WATER BILL.

A MEETING of the Committee of the petitioners against this Bill was lately held in the Royal Hotel, Princes' street, with a view to consider what further steps should be taken by the petitioners, having regard to the position now taken up by the promoters of the Bill. It was unanimously resolved to oppose by counsel the Bill as now before Parliament, and a sub-committee was appointed to carry out this resolution.

ST. ANDREW'S UNIVERSITY.

THE General Council of this University held a meeting on Thursday last in the hall of the United College of St. Salvador and St. Leonards. Principal Shairp occupied the chair. The Council proceeded to elect an assessor in the room of the Hon. Lord Jerviswoode, whose term of office had expired. A letter was read by the chairman from Lord Jerviswoode expressing his deep sense of the honour shown him in electing him as assessor on former occasions, and his regret that he could not again request their suffrages.

Dr. Cleghorn was then proposed by Rev. Mr. Thomson, who said that Lord Jerviswoode was one well worthy of the position to which he had been before appointed, and one whom, if it had seemed good to his lordship to have continued in the office, they would have been thankful to re-elect. The gentleman whom he begged to propose had claims of a local nature, and claims also of a more general character. Dr. Cleghorn had been a distinguished student in philosophy in their own University, whence he had gone to Edinburgh to follow that higher course of science which was to qualify him for the medical profession. He resided in their neighbourhood, with time and ability very much at his disposal; and was one whose amiable disposition, gentlemanly manners, and tried discretion, would make him a most agreeable companion to his colleagues in the University Court.

Dr. Lindsay seconded the motion, after which Professor Macdonald, whilst acknowledging the claims and eminence of Dr. Cleghorn, begged to propose Dr. Richardson, of London, a very skilled physiologist and experimentalist, who held a position in the St. Andrews Medical Graduates Association in London, which was industriously occupied in endeavouring to get the extension of the privileges of the University, and the restoration to the University of the power of granting medical degrees. He believed that Dr. Richardson would be ready at all times to attend the meetings of the Council.

Mr. W. Robb seconded the proposal. There were no other candidates, and a show of hands being called for, only the proposer and seconder voted for Dr. Richardson. The rest were for Dr. Cleghorn. A poll on behalf of Dr. Richardson was demanded, and after some remarks by various speakers, the clerk was ordered to make arrangements for the poll.

◆

THE CLIMATE OF NICE.

(FROM AN OCCASIONAL CORRESPONDENT.)

NICE, *March* 14, 1869.

SINCE I last wrote to you* my prediction has been amply fulfilled. March did indeed "come in like a lion" here. I only hope it may "go out like a lamb," as the old English proverb has it. We have had a whole fortnight of the dreaded mistral wind and its accompanying dust. No tongue can tell the irritating qualities of such a time. Those who have experienced it once usually flee before it, or shut themselves up in the house. Many families have hurried on to Rome, Pisa, Naples, or other more genial climes. Some have turned their steps towards Pau, a sedative and damp climate, that is likely to relieve the extreme tension produced by this. Others have ventured to Florence, where, though much colder at times, and not seldom equally irritating, there is more amusement, and for those who have not yet been, a new world to see. Some have gone over to Cannes, Mentone, or San Remo. Of these the last is decidedly preferable, being the most sheltered from the mistral and the cleanest. Cannes is cooler than Nice, its hills are lower, and this year so few people have stayed there that it is excessively dull; yet to those who care not for society it is an agreeable resort. Mentone, so much lauded by interested parties, is in a state as bad as Nice. Its drainage is in a terribly defective condition; filthy smells assail you at every turn; the shopkeepers are as extortionate as at Nice, and there are literally no walks for those who cannot climb lofty hills. This may surprise some; I can only say it is the result of more than one visit this winter. I would tell you more—those who speak of Mentone being only open to the south, are in direct contradiction with the compass. You may believe which witness you please; I confess to a leaning towards the compass. The advantage over Cannes and Mentone possessed by San Remo is considerable. Its value has been pointed out with precision, and its position as a sheltered nook, and its many charms, are explained from a medical point of view in Dr. Prosser James's pamphlet, and from a patient's view, in the charming production of Mr. Aspinwell, published by Churchill and Sons.

There is another refuge nearer than any of those which some of my friends have sought this year,—it is Cimiez, a retreat on a hill, some half-hour's drive from Nice. It is much milder there. The wind is much less felt, and instead of being choked with dust, the visitor is there surrounded with a lovely vegetation. Its inconvenience is, that except for good walkers, it is a long way off from everything that may be wanted, and you are obliged to send down to the town for a carriage when you want one, as indeed for every trifle. There is no hotel there, and boarding-houses are never equal to hotels. There are some good villas, suitable for families who would like to spend a winter there.

All the places I have named are sought, but the great stream is ever onwards, and Rome is the favourite resort. Of all places this seems the best suited to any who have suffered from Nice, and who dare not face a damp place like Pisa or Pau. I see from the English papers that you have had a rough March at home, and year after year I have observed that such weather coincides with our mistral here. It has really been very destructive to those whose respiratory mucous membrane is irritable; and I cannot too strongly urge such persons to be cautious how they come here, much more how they stay till spring. Not that cold is the evil,—for though it has been excessively keen this last fortnight, though the frost has done much damage to the fruit, and the ice in certain parts has been unusually thick, we could bear that well, but for the irritating nature of the wind. There are plenty of places where the average temperature is below this, but where you do not *feel* it so cold. The sun is very powerful at times, so that the transitions are too rapid. Such stimulation one can easily see may be good in some diseases; but for delicate chests nothing can be worse; while hæmoptysis is very often produced by it, to say nothing of the frequency with which it is aggravated when those suffering from it were here. It is very desirable that London physicians should exercise greater care in the selection of the places to which they send their patients; and I cannot but feel, after all I have seen, how necessary it is to warn those who have not a lengthy experience of these climates, of the dangers with which they teem. It is so easy to mistake a case, and the consequences are so serious, that patients ought not to be sent abroad with any vague notions, at the risk of injuring themselves and destroying the reputations of their advisers. It would be much safer to call into consultation one of those physicians who have passed several seasons in these treacherous climates, and whose advice must be more practical as well as more valuable.

---

* The letter about Nice, which appeared in our number of the 10th inst., was from a different correspondent It was, in fact, dated Paris, and should have appeared in the previous letter of our correspondent, but in postponing, the wrong portion was taken out by a mistake of the printer.—[ED.]

Notes on Current Topics.

"An Antient and Fish-like Smell."

A VERY important report on the sale of putrid fish in London has been recently presented to the Marylebone Vestry by their Medical Officer of Health, and furnished by direction of the vestry to the London Common Council. The report stated that it was high time means were adopted to put a stop to the sale of putrid and unsound fish at Billingsgate-market. Not a week, it stated, passed that one or other of the inspectors of that parish was not called upon to destroy large quantities of it, brought to them by costermongers and small dealers, who had purchased it at the Dutch auctions, which are daily held there, on the assurance of the vendors that it was sound and fresh. The quantity destroyed by them during the last month, as being unfit for food, exceeded 600lb., and during the year ending with the last month amounted to 4,490lb. Assuming, says the medical officer, that the parish of Marylebone contains one-twentieth part of the population of the entire metropolis, which is very nearly the fact, and that the quantity of unsound fish destroyed in it is a fair average of the amount of fish in a similar condition sent to other districts, regard being had to the number of their respective populations, it follows that every year 40 tons of an important article of the food of the humbler classes is sent out from Billingsgate-market altogether unfit for human consumption. But this, the medical officer says, by no means constitutes all the fish sold at the market, which is equally unfit to be eaten, a vast quantity of it being daily sold on the street barrows and in small shops in poor neighbourhoods, so stale and unsound that although its condition may not be immediately detected, it is not the less pernicious or dangerous to those who eat it. Among the destitute poor of that parish diarrhœa is more or less prevalent at all seasons of the year, and he could imagine nothing more calculated to produce it than the eating of unsound fish. On the motion of Mr. Pedler, the subject was referred to the markets committee and the commissioners of sewers, for consideration and report.

It is right that the public should be aware that there is something more in the selling of putrid fish than the fraud on the consumer, who buys it as fresh, a system which, we presume, Mr. Bright would say, comes under the same category as adulteration, and is, therefore, perfectly compatible with his ideas of free trade. In putrid flesh, and especially in shell-fish and sausages, an undefined poison is often generated of the most dangerous character of irritant poisons. Many persons have been killed by it, and hundreds suffer serious illness; and in point of fact the wares of the hawker of stall fish may be, and are not unusually, as deleterious as if a certain proportion of his stock were stuffed with an irritant poison.

Via Medica.

THE best, indeed the only reliable, authority on the purchase and sale of medical practices, with which Mr. J. B. Langley has furnished the profession, has just appeared for the third time in response to the requirements of the profession. Less than eighteen months have sufficed to circulate two large editions of the book, and we shall be surprised if the third be more tardy in its sale. The present edition embraces all the new points of law and custom in the general law of master and servant, and in the professional *mos pro lege* in relation to medical assistants. The alterations of the Act of 1867 are embodied in it; and reference is made to the New Pharmacy Act, the provisions of which of themselves would have given rise to the necessity for a new issue of the book. The portions referring to the microscope and books of reference have also followed the progress of medical literature.

The book displays throughout a commendable absence of the self-recommendation, a feature which some medical authors might judiciously plagiarise; and we believe that the straightforward frankness of the information it contains is in the highest degree calculated to enable the profession who may consult its pages to think for themselves, and by putting purchasers and sellers in the position of "looking before they leap," to put such bargains on the safest and most satisfactory footing.

Rigollot's Mustard Leaves.

THESE new and convenient sinapisms, which have recently been introduced into England by a French manufacturer, will, we anticipate, be accepted by the profession as a much-wanted convenience, especially in private practice. There are, without doubt, disadvantages in the ordinary mustard poultice which should bring any efficient substitute into favour. A sinapism is ordered to the chest, say for a heavy cold, and the physician leaves its application with the servant or nurse. First, there is a delay while the mustard is sent for; then the poultice is made, perhaps with so much water that the sinapism trickles down inside the patient's clothing, perhaps with too little, and the poultice is a doughy lump; then the mustard may be fiery, and raises a great blister, or it may have been doing duty in the grocer's window for six months, and be little better than flour and turmeric.

All these contingencies, with all the failures consequent on them, have been long since felt, and have brought into use tissues made with oil of mustard, which, however, were found to be uncertain in their action, in some cases violent, in others comparatively inert.

Rigollot's mustard leaves are apparently nothing else than strong mustard powder spread on paper. They are sold in tight tin cases, such as may be carried in the pocket, and their application consists simply in dipping them in water and applying them to the skin. The experiments which we have made with it indicate that it is much more vigorous and effective than the mustard poultice. In every case the plaster began to give pain in, at most, one minute, causing active determination of blood to the part in from three to eight minutes. In one of the cases, a man whose skin had never been affected in the slightest degree either by mustard poultices or cantharides, it acted energetically in eight minutes. On economic grounds these sinapisms also recommend themselves, for they will act almost as well a second time as when quite fresh.

As far as our experience goes, they give promise of supplanting the old mustard poultice on all the grounds of efficiency, cleanliness, and convenience.

The Neil Arnott Exhibition in Physical Science.

Dr. Neil Arnott having offered to the University of London the sum of £2,000, with the view of encouraging the promotion of the study of physical science through the examinations of the University, the senate at its last meeting adopted the following resolution :—"That the sum of £2,000, presented by Dr. Arnott to the Vice-Chancellor for the University of London, be accepted by the senate; and that the annual interest thereof be applied to the purpose approved by him, viz., to the institution of an exhibition and medal for proficiency in experimental physics, entitled the Neil Arnott Exhibition and Medal, at the Honours Examination for First B.Sc. and Preliminary Scientific M.B., the exhibition being of the amount of £40 per annum, tenable for two years." In accepting this munificent present, the senate desired to record their grateful sense of Dr. Arnott's enlightened liberality, as well as the satisfaction which they felt in associating their recompense in experimental physics with the name of a member of their body who has contributed so powerfully both to the lucid exposition of physical science in theory, and to the useful application of it in practice.

Paris Milk.

The *Constitutionel* informs us that the average consumption of milk in Paris is 500,000 litres, at the price of 25c. the litre, to which are added 50,000 litres of water, which places the fraud on the consumers at just 4,500,000f. a-year. This fraud is effected successively by the producer, who sells skimmed milk, and often the same with water. The milk merchant again dilutes the liquid, and lastly the "Cremier-laitier" completes the deluge. The price of 25c. is not sufficiently remunerative; therefore, a fraud is persisted in which even expert chemists are powerless to detect, because there exists no normal standard of quality. Nor can such exist, because the density of the milk varies from many causes, which depend on the animal that gives it, its feeding, its locality, and the period of its milking.

The Dialectical Remedy for Pauperism.

It is hardly necessary for us to disclaim any intention of identifying the Dialectical Society or Lord Amberley with the horrible proposals of Marcus, which are unveiled by Dr. Whittle in a communication which we publish to-day. We should indeed have hesitated in reproducing such abominable suggestions in our pages, but that we hold that when it is deliberately stated in a society of "progressive Liberals" that the restriction of population is altogether a question of medical possibility, the hour has passed for moral modesty.

It may be too much to ask the Dialectics by what means they propose to restrict families, but when the Society declares the natural remedy of abstinence to be impossible, and perhaps undesirable, we are at a loss to select from the only remaining alternatives—prostitution, abortion, or infanticide.

Sir Patrick Dun's Hospital, Dublin.

The memorial to the Provost, Vice-Provost, and Senior Fellows of the University of Dublin, with regard to the partial monopoly now enjoyed by Sir Patrick Dun's Hospital of the hospital attendance of candidates for the medical degrees of the University has, we understand, received the signatures already of five-sixths of the physicians and surgeons of clinical hospitals in Dublin. It has been endorsed almost unanimously by the medical officers of the Meath, Adelaide, City of Dublin, Jervis Street, St. Vincent's, and Steevens' Hospitals, and it is anticipated that the clinical staff of other hospitals, whose replies have not yet been received, will join the great majority of their brethren in the effort to bring the matter forcibly under the notice of the authorities of Trinity College.

It was found impossible to complete the signatures to the memorial in time for presentation to the Board on last Saturday.

We should imagine that, even on the part of those interested in Sir Patrick Dun's Hospital and the School of Physic, an opposition to the prayer of the memorial would be considered short-sighted and injudicious. Even from so restricted a point of view it would appear desirable to remove the hindrance which now exists to the great majority of the medical students of Dublin in seeking their qualification for the University.

The "Lancet" and the Prospect of Reforming the Council.

We noticed a little while ago the strange fact that the reticence of the *Lancet* on the subject of reforming the Council had been broken in an unusual manner. It will be remembered that last summer, when the election for the Scotch Universities was on hand, and one candidate had risked all on this one question, our scrupulous contemporary, having fully committed itself to the support of a non-medical candidate, not only ignored the question, but burked the simple facts of the contest. Electioneering zeal of this kind is comprehensible if not excusable, but the end is not yet. After Dr. P. James had retired from the contest in favour of Prof. Playfair, who had accepted his plan of medical reform, we might have imagined that the *Lancet* would no longer ignore the question. What of the facts? Only after Dr. James's health failed, and in accordance with the advice of his friends, who recommended a winter on the Nile or in Rome, he had left the country, did the *Lancet* think it time to bring forward the subject. Then it adopts almost the plan matured so long ago, and which the profession has unequivocally approved, and brings it forward as if evolved out of its own consciousness, instead of having been stolen from the invalided reformer and *quondam* candidate.

We have no doubt at all that that gentleman will be glad to hear of any support, whatever the motive and however ungraciously given, since it is clear he only cares to establish the principle. We are also equally convinced that the profession will be more willing than the staff of the *Lancet* to render the honour to the reformer who has fought the fight. The very plan which the *Lancet* has asked Dr. Morris to try in the case of the College of Surgeons of England has already been tried in reference to other bodies. We are enabled to state that Dr. James had spent a considerable sum in this matter when his impaired health put a stop to further proceedings. It is not unlikely he may be able to furnish valuable assistance, and we are sure the profession will echo our wish that he may soon return home with renewed health, and be able to take part in the next campaign for medical reform.

It is said that her Majesty has become patroness of the Booksellers' Provident Institution, and testified her sympathy with its objects by a substantial donation to its funds.

We are informed that the Branch of the Medical Council for England will meet to-day, in preparation for the meeting of the General Council.

The office of Physician in King's College will still be held by Dr. Lionel Beale, though he has resigned the Professorship of Physiology in the College.

As a sufficient sum was not realized at the Leeds Art Exhibition to clear off the debt on the Infirmary, a meeting was lately held, at which the mayor presided, when £10,000 was subscribed for that object.

The Bill for the promotion of medical science, legalizing the study of anatomy, by allowing physicians to legitimately obtain subjects for dissection, was passed in the Maine Senate, Feb. 24 by a vote of 14 to 10.

Her Majesty, who takes great interest in the National Cottage Hospital for Consumption and Diseases of the Chest, at Ventnor, has, we learn, consented to depute a member of the Royal Family to lay the foundation stone of the second pair of buildings in July next.

The *Daily News* informs us that Her Royal Highness the Princess Louise honoured Miss Garrett, L.S.A., of Upper Berkeley street, with a visit a few days since. Her Royal Highness made some inquiries respecting the prospects of medical education for women in this country, and expressed much sympathy with Miss Garrett's wish to see the medical profession completely opened to women.

The Premier has expressed a wish that the money recently collected in Liverpool and the district, for the "Gladstone Testimonial," should be expended upon a Convalescent Hospital. Mrs. Gladstone is expected to lay the foundation stone, and in the evening it is believed that Mr. Gladstone will address a meeting of working men in Hengler's Circus.

On Tuesday, the 23rd inst., a meeting of the City Commissioners of Sewers was held at the Guildhall, when a report from the Sanitary Committee was presented condemning a number of houses in Sun court, Golden lane, as unfit for human habitation. A discussion of some length followed as to the authority of the Commissioners, and what was meant by a house being "unfit for habitation." The report was finally adopted, and the houses will accordingly be demolished.

Mr. Thomas Crowley, of Birmingham, who died at the commencement of the present month, gave in January last the sum of £10,000 for the foundation of an orphan asylum for girls in that town; and at his death, besides various other liberal bequests, he has given £1,000 each to the Queen's Hospital and the Deaf and Dumb Institution, and £500 each to the Birmingham General Hospital, the Blind Asylum, and the Eye Hospital.

A General Session of the St. Andrew's Medical Graduates' Association will be held in the rooms of the Medical Society of London, 32a, George street, Hanover Square, on Thursday, 8th April. C. Eckhard, M.D., Professor of Physiology in the University of Giessen, will read a paper on "Hydruria" after the ordinary business has been transacted.

The Senate of the University of London have passed the following ordinance in reference to their degrees in medicine and surgery:—"That candidates for the M.D. and M.S. degrees be admitted to the examinations for those degrees in logic and moral philosophy alone, in any year after having obtained the degree of M.B.; and that after passing this examination, they may present themselves for examination in medicine alone or in surgery alone (as the case may be) at any M.D. or M.S. examination at which they are admissible under the existing regulations."

BRITISH MEDICAL ASSOCIATION.—MEETING OF THE METROPOLITAN COUNTIES' BRANCH.

THE QUESTION OF SPECIAL HOSPITALS.

At the adjourned meeting of the Metropolitan Counties Branch of the British Medical Association, the discussion on Hospital Administration was resumed. The first portion of the evening was taken up by the views of members on the system of Governors' letters. While a few upheld them, the preponderance of opinion and of evidence was decidedly adverse to their issue. In their place some members recommended the free system, and others either district bureaux or one central bureau, after the Parisian model. But it is much too soon to propose any substitute for Governors' letters. The basis on which our hospitals are in future to rest must first be decided. Is it to remain, as at present, of a voluntary character without State interference, or is there to be a national system of medical relief, and a subordination of the voluntary institutions to central control, wisely and discreetly exercised? Until the answer is rendered to this question the suitable remedial substitute for Governors' letters cannot be applied.

The debate on Special Departments and Special Hospitals was of a more lively and interesting character.

Dr. **Beigel**, who was the first to rise, made "a hit—a hit, a very palpable hit." Amid general laughter and applause he said that in Paris, when a man was well acquainted with a particular subject he became naturally a teacher of that subject; but in England, if a physician had become a distinguished authority on diseases of the throat, he was fortunate if after a time he received the Chair of Botany, and subsequently was promoted to the Chair of Physiology.

He was followed by Mr. WALTER COULSON, who replied very fairly and temperately to some of the stock arguments against special hospitals, and was fortunate enough nearly to make a convert of Dr. Down, who appeared to have been previously in a middle state, something like Mahomet's coffin suspended between earth and heaven.

Dr. DOWN, however, still retained a few doubts as to the need for special hospitals, which he put before the meeting in the way of interrogation. Both Dr. Down's and Mr. Coulson's remarks were of a most peaceful character, but Dr. Forbes Winslow, who spoke before Dr. Down, had introduced a warlike element into the discussion, by expressing a most decided opinion against the Hospital for Diseases of the Throat. This opinion, which was reiterated to make it more emphatic, was unsupported by any argument, and subsequently refuted, to all intents and purposes, by the speaker himself, to the dismay of one or two gentlemen who had cheered the assertion that there was no need of the hospital.

Naturally enough, Dr. MORELL MACKENZIE rose up in arms against Dr. Winslow, and requested to be informed how the ground on which the Throat Hospital rested differed from that which supported the Orthopædic and the Ophthalmic Hospitals. No one ventured to reply to the pointed and puzzling inquiry, and until it is answered the opponents of the hospital must continue on the losing side.

The remaining and principal portion of Dr. Mackenzie's speech was a very able exposition of the merits of special hospitals, and the disadvantages of cutting up the general hospitals into too many special departments. He showed clearly that, on the basis of the statistics published in the *Times*, the cost of each patient at the special hospitals was one pound less than at the general hospitals, and the effect of this unexpected announcement was not obliterated by the attempts of Mr. Heath and Mr. Hart to throw discredit on the statistics. Unless those who dispute them can produce more accurate statistics which clearly prove that the cost of patients is less at the general than the special hospitals, what right have opponents of special hospitals to go on asserting, as they continually do, a proposition in support of which actual figures are never adduced, because they are not forthcoming? Dr. Mackenzie concluded his eloquent speech by upholding the principle of demand and supply, and expressing his readiness to appeal unto Cæsar.

Mr. DRYSDALE thought that the great desideratum was to have a central school connected with the Academy of Medicine which was now in contemplation. In the meantime, special hospitals were most useful institutions.

Mr. HEATH said that the expenses of general hospitals could not be compared with special hospitals, because the cases in special hospitals were not so severe as those in general hospitals. He complained of special hospitals treating cases beyond their province, and he made some amusing comments on the division of the human body amongst the specialists, and the sanction given to each portion by placing it under the patronage of a saint. He criticised Dr. Mackenzie's financial statements.

Mr. TEEVAN took pains to show that St. Peter's Hospital was not antagonistic to the general practitioner, and argued that special hospitals might be built close to general hospitals.

Dr. STEWART laid down two principles for the establishment of special hospitals—the refusal of cases at the general hospitals, and the deficiency of the necessary apparatus for treating certain classes of disease.

The last speaker before Mr. HART replied was Mr. RIVINGTON. Keeping close to the two points of the question before the meeting, he showed how the special departments required by the general hospitals for elementary education could only be rendered efficient by the officers of the departments having the requisite leisure to throw their energies into them, and the time for teaching, by being supported by a subordinate staff of advanced students or clinical assistants, and by the departments being as nearly as possible copies of the best special hospitals. With regard to special hospitals, he was convinced that under any system a certain number would be required. The question to be solved was, how to prevent their over-multiplication as independent institutions unconnected with education of students. He would like to see some of the ophthalmic hospitals and orthopædic hospitals amalgamated, and all objections to special hospitals would be removed by their being national institutions, freely opening their appointments, having the best men attached to them, being made accurate models of scientific practice and higher schools for students of special diseases, useful alike to the general practitioner and the foreigner desirous of comparing English with Continental methods. He was not in favour of leaving hospitals to the laws of demand and supply, and looked forward to a time when there would be organisation, without undue interference with voluntary efforts; and State control, without abrogation of the independent autonomy of individual institutions.

Mr. HART made a brief reply. He disputed the soundness of Dr. Mackenzie's views of demand and supply, facetiously remarking that a constant demand for money was not always a constant supply.

Finally, a Committee was appointed to take all the questions introduced by Mr. Hart into consideration.

Correspondence.

THE COMPANY OF APOTHECARIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,— In a late issue, an unjust attack was made upon the Company of Apothecaries. They doubtless esteem it not an honour to be attacked through the medium of the *Pharmaceutical* or any other journal.

I have not as yet seen the *Pharmaceutical Journal*, and therefore excepting the quotation you animadverted upon, know nothing of what it says on the subject. That quotation most decidely leaves a totally wrong impression on the mind, as regards the intentions of the Company.

The Apothecaries Company is endeavouring to obtain power to found a School of Pharmacy and grant licenses in the same, similar in every respect to those at present granted by the Pharmaceutical Society of Great Britain, the latter Society offering no opposition.

The Apothecaries Company have done nothing that would lead any sane minded person to believe they intended abrogating "their legitimate function of controlling the practice of pharmacy in Ireland." Whether such is their legitimate function, opens a new phase of the matter altogether. They may be looked on as medical practitioners to whom, in 1815, practical pharmacy was entrusted by the legislature. As such they possess a perfect right to say to the legislature: "In our opinion, pharmacy has grown into an art so great that it would be for the good of all if it were entrusted to a class of individuals who should make it their sole care."

The licence of the Company is not, and never was represented to be, a surgical one. It professes to empower the possessor to practice medicine and pharmacy in any part of Her Majesty's dominions, and most justly so. Its examinations are every whit as severe, if not more so, than those of a goodly number of its neighbours. It is very lamentable indeed that apothecaries cannot make incompatibles combine when ordered to do so by some very clever doctor, who, when at college always found them mixed. An apothecary must have served an apprenticeship of at least three years, and is practical pharmacy so vast a subject as not to be throughly mastered in that time? In "Via Medica," Mr. Langley says that he is receiving constant applications from gentlemen of the Sister Isle for situations, where they will have no club or dispensary practice, no midwifery, &c. He adds that they, on being asked who is to do the shop work and keep the accounts, look puzzled, and are not unfrequently indignant at the idea of what they consider degrading work, spurning which, they enter the army or navy.

It is extremely probable that such gentlemen would make very good assistants, "as soon as they had acquired a little knowledge of the apothecary's art." But these applications do not come from, and these observations do not apply to, the ex-apprentices of an Irish apothecary.

M. D. CROFTON.

HISTORY OF THE LICENSING SYSTEM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Parliament is again asked to revise the Licensing System; the present time is therefore suitable for resuming the sketch of English liquor laws.

In the reign of Charles I. (1635), Lord Coventry, in addressing the Judges, said :—"I account ale-houses and tippling-houses the greatest pests in the kingdom. Public-houses are the public stages of drunkenness and disorder." Corrective measures were tried, but they were partial and powerless.

The Puritans and the Long Parliament did not mend matters when, in 1643, they enforced the Act of James I., requiring a quart of strong ale to be sold for a penny. The State became further compromised by levying excise duties upon intoxicants.

During the Restoration (1660) the drinking dens were the scenes of shameless profligacy ; yet Parliament did nothing. One member (Mr. Stevens) advocated a law "against drinking of healths ;" but he found no supporter.

Times of war and an embarrassed exchequer are unfavourable to social reform and the reduction of taxation. In the reigns of William and Mary, then of William alone, and afterwards of Anne, the making and selling of ardent spirits was stimulated in order to increase the revenue. Distillers were permitted to sell spirits without a license, if they did not permit "tippling" on their premises. Vendors increased at an alarming rate. Maitland, in 1725, estimated that gin was sold at every sixth house in London. The consumption of this fiery drink increased in forty years (1684 to 1724) from 524,000 gallons to 3,520,000 gallons. Horrible debauchery resulted, and higher duties were then imposed, with further restrictive legislation.

Hogarth, in his "Gin lane," and "Beer street," taught that fermented liquors were comparatively harmless, and this popular delusion led to that important alteration of the Licensing System, the Beer Act, which was passed in the supposed interests of sobriety, but has flooded England and Wales with intemperance. This Act was passed in 1830, and for more than a generation it has been an ubiquitous temptation to excess. The Beer Act is now universally condemned, and is certain to be soon repealed or modified. Lord Brougham, one of its promoters, introduced a bill to stop drinking "on the premises," but the measure did not reach the House of Commons.

Mr. Gladstone's Wine Licence Act of 1860 was intended as another improvement of the Licensing System ; it is believed, however, to have caused mischief ; so have the "occasional licences." The Night Closing Act of 1864-5 has worked well.

The chief sufferers from the present Licensing System are the working classes ; and consequently they are largely in favour of Sir Wilfrid Lawson's Permissive Prohibitory Liquor Bill, the second reading of which is fixed for May 12. This measure is applicable to the whole of the United Kingdom, and it would operate by empowering a majority of two-thirds of the inhabitants of any parish or district to stop the issue of licences for the sale of intoxicating drinks ; in short, it embodies Mr. Gladstone's idea of "local option."

Manchester. HENRY PITMAN.

THE TRUTH ABOUT NICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have had nearly as lengthy an experience of the winter climate of Nice as "G. P.," whose letter appears in your journal of the 3rd inst., and I can corroborate what he says, as well as bear testimony to the justice of the indignant protests of Dr. Hawkins, and your "Occasional Correspondent," respecting the sanitary condition of that health resort. The state of the drainage, so truthfully set forth in your columns, is enough to bring a fearful pestilence on the town ; and Dr. Hawkins' prophecy of it getting worse as the season advanced has come true. Since the date of his letter, the nuisance has gone on increasing, and I, as well as some families of my acquaintance, have been driven away to other resorts by the filth and the stench that those who have the welfare of the town at heart ought to remove. I, and others, would have braved the March winds—bad as they are—but for the additional burden of danger from the drains. Who could put up with both evils ! You may shelter yourself to some degree from wind, by remaining indoors ; but at your peril ! for then the untrapped, or imperfectly trapped, water-closets and sinks, which all end in a cesspool under the house, have you under their dominion so many hours more. Whether you are in hotel, boarding-house, or a lodging, or have a villa, the same sword of Damocles hangs over you. No other mode of drainage exists, and a really good and simple trap was unknown until four years ago I brought some from England and presented to my landlord. Few others have adopted them, and all their contrivances are rendered nugatory by the carelessness of servants. You cannot keep your windows all open during the March winds, and therefore it is best to leave for some other resort—particularly as in nine cases out of ten March is a bad time for any invalid at Nice.

I am, &c.,

Paris, March 14. J. C.

◆

HOSPITAL ADMINISTRATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The writer of the excellent and sensible article on the above-named subject in your paper of March 17, has words to the effect that it seems absurd that none of the proceeds of such a charity as a hospital should go towards paying those medical officers without whose aid the charity could no longer maintain its operations.

I believe, in the first place, that a very large proportion of the British public, reading these remarks, would express unfeigned amazement when they learned how highly educated physicians and surgeons were content to give two or more afternoons per week to the laborious work of seeing hospital out-patients without any payment for time and energy thus spent.

Some would say, "Well, there are plenty of good doctors ready enough to come and work for nothing, so why should our funds, poor enough already, be further strained to pay the doctors ?"

It is undoubtedly one of the privileges of the medical profession to do invaluable good without desiring or expecting any payment ; but because doctors are thus ready to work for nothing is no reason why arduous public services should be expected at their hands, under the superintendence of a board or committee, for no remuneration. It was all very well for some distinguished man to say he would undertake to officer her Majesty's army with gentlemen who would gladly do the work for nothing. Officers in the army are usually men of independent fortune, and pay is hardly a necessity, though what an army might be when dependent on "gratis service," can better be imagined than described.

Doctors commencing practice are fairly presumed to be men seeking a living, with house rent to pay and families to keep and feed, and £50 or £100 a-year to a young physician or surgeon is no small help and encouragement to him when setting forth on the uncertain path of London practice.

The great question is—Where is the money to came from ? And here is the difficulty, for in these days, when hospitals are so numerous, the demands upon their resources so pressing, and the competition for public patronage and support so active, it is in most instances as much as ever the unendowed hospitals can do to pay their way, and to burden them further with a demand for salaries for their medical officers, seems hard.

Would it, however, be absolutely uncharitable to require the small payment of one penny from out-patients on every occasion of their receiving a fresh bottle of medicine ? I am acquainted with an old dispensary of good repute in London where this plan of penny payments has been long pursued, and the effect has been to add about £100 a-year to the annual income of the dispensary directly, and indirectly to prevent the patients from wasting their medicine, thus saving again in the drug bill.

From what I have seen of the poor and their habits, is that they would think all the more highly of advice and medicine for which they paid something. I need not remind my readers of that learned physician who, whenever he looked at his own tongue and took physic, always took a guinea from one pocket and put into another, to confer some value on the dose administered.

The small payment would tend to choke off idlers and malingerers from obstructing the real work of the out-patient room, and so tend to bring the duties of the medical officer down to within the powers of a mortal man really anxious to do his very best for his patients, instead of having to scramble through a herd of cases as fast as possible, and then leave off utterly unfit for anything but to lie and rest on the sofa all the evening.

The direct increase of income which hospitals and dispensaries would acquire by the adoption of something like a self-supporting method, I would have to be divided among the assistant medical officers. Thus, these hard-working men would be encouraged; the posts they fill would rise in the estimation of the public, the patients, and the profession; the doctors would feel that they had no right to hurry over the work, for their time was fairly paid for; and the patients would feel that they were contributing their mite to the welfare of an institution which was ever ready with substantial succour for them in their hour of need.

I am, Sir,
Obediently yours,
J. C. T.

◆

THE VALUE OF PANCREATIC EMULSION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It is obvious that the true value of a remedy cannot efficiently be laid before the profession by one or two papers appearing from time to time, and at, perhaps, long intervals in the pages of a periodical. Again, those men who write and publish their experience are only a few out of very many practising physicians, and so we only get in this way a limited amount of evidence with regard to the beneficial action, or the reverse, of any remedy. Again, it would be impracticable for any medical journal to publish the reports of all the medical men who have used any given medicinal, supposing them all to be willing to record their experience.

Now, Sir, wishing to obviate these difficulties with regard to a remedy of which I have had some experience, and for which there has arisen a very large and increasing demand, as the manufacturers, Messrs. Savory and Moore, have informed me, I have undertaken the task of collecting the results of the experiences of medical men in Ireland who have used pancreatic emulsion of fat in the treatment of pulmonary consumption.

To obtain the opinions as to its value from the Irish medical men who have used the emulsion I only see two ways—either to send a schedule of questions to every registered medical practitioner in Ireland, which would entail an immensity of labour and expense, or to adopt the plan which I am now putting into execution, of requesting, through the medium of the Medical Press and Circular, those gentlemen who have any experience in the use of the emulsion to send me their names and addresses. I will then send them a schedule of questions, and on receipt of a sufficient number of answers I will fairly and impartially tabulate and publish the same with as little delay as possible.

I am, Sir, yours, &c.,
Richard Kinkead, A.B.T.C.D., &c.

◆

SUPERANNUATION ALLOWANCES TO MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I should feel obliged if you would permit me, through your journal, to make an appeal to members of the English Poor-law Medical Officers' Association especially, and Poor-law medical officers generally, under the following circumstances:

In December, 1868, I was deputed by the Council of the Association to write to the secretary of the Irish Medical Association, and tender an interchange of good offices in furtherance of the objects of the respective Associations. This offer was gladly accepted by the Council of the Irish Association.

The time has now arrived when English Poor-law medical officers can afford a practical demonstration of sympathy with their Irish brethren. On the 7th of April the Bill to provide for Superannuation Allowances to Medical Officers of Poor-law Unions and of Dispensary Districts of such Unions in Ireland, introduced by Dr. Brady, will be read a second time. The object of the Bill is fully described in its title, but, in order to make it more plain, I may state that it is intended thereby to provide, "with the concurrence of boards of guardians and the Irish Poor-law Commissioners, superannuation allowances to any medical officer or officers of a union or dispensary district who shall at any time after his or their appointment become incapable of discharging the duty of his or their office with efficiency, by reason of infirmity of mind or body, or old age, upon his or their resigning or ceasing to hold office, such annual allowance for his or their lives not exceeding in any case two-thirds of the income derived by such office or offices," &c.

Having communicated with Dr. Brady and others, they agreed with me in considering that great assistance might be afforded at the second reading if English and Welsh Poor-law medical officers would at once write to such Members of the House of Commons as they may be personally acquainted with, and urge them to vote for the Bill. With a view to afford in a ready form the material of such letter, I would suggest the adoption of part of the speech of Mr. B. Baker at the last quarterly meeting of our Association, on moving a resolution upon this subject: "Our education costs us much; we devote much time and thought in our department; our work is most difficult and most ungrateful, and fraught with much personal risk to ourselves and families. We work seven days a week, ofttimes at night, all the year round. There is no provision made for a vacation. The parish doctor is never supposed to be idle—never to be tired—never to want a change from the monotonous duties of his office; if he leaves his appointment, it must be at his own risk and cost."

The argument used against superannuation of Poor-law medical officers is that they do not give the whole of their time. To this it may be replied that the salaries paid are wholly insufficient to enable them to do so; but they are expected to be ready at all times, even at the sacrifice too frequently of other more remunerative interests.

I may further state that a direct appeal will be made, through the Council of the Association, to those English and Welsh members who, to the number of ninety, replied favourably to our circular letter at the late election. But I must urge upon gentlemen the desirability of supporting our application by immediate oral or written request to those they can influence.

In conclusion, let me remind Poor-law medical officers that our Irish *confrères* are not likely to be wanting in grateful recognition of our services; and if they are afforded on this occasion, we shall have the right to ask and be sure to obtain a similar service from them when the time arrives to make that parliamentary appeal for the redress of grievances which it is the object of the Poor-law Medical Officers' Association to secure.

I am, Sir, yours obediently,
J. Rogers.

Dean street, London, W.C., March, 1869.

Literature.

METRITIS AND PARAMETRITIS.*

The works of Duncan on Obstetrics and on Fecundity and Sterility have excited much attention from the medical and also from the general press, and this is the less to be wondered at, because the author has a very agreeble way of expressing himself, an art perhaps too little cultivated by members of the profession of medicine. The diseases of which the author speaks in this work are the occasion of much controversy among writers on the diseases of women; and thus there is not as yet much known about them. With regard to nomenclature. Dr. Duncan rejects the name *pelvic abscess*, because the diseases he speaks of do not often end in abscess, and often extend beyond the pelvis. *Pelvic cellulitis* also he rejects, because the diseases he describes are not in the cellular tissue. *Peri-uterine* he thinks is a bad compound. He follows Virchow in using the word *peri* for inflammations of serous membranes, and *para* for inflammations of cellular or connective tissue. Thus "perimetritis" will mean inflammation of the uterine peritoneum, and "parametritis", inflammation of the cellular tissue, in connection with the womb.

There are only, our author truly remarks, a few cases in which we can assert, during life at least, that the pelvic peritonitis is perimetritis, or some other inflammation, and he therefore uses the one term to include all forms whether connected with the womb or its appendages. The work before us, then, is a treatise on inflammation and abscess in connection with uterine, tubal, and ovarian disease. One of the earliest works in the English language which deserves to be mentioned in reference to this subject, is the communication of Dr. Doherty to the *Dublin Journal of Medical Science* of 1843. He there describes the hard tumour felt at the roof of the vagina after parturition, and the fixed condition of the uterus. In a list of 16 autopsies given by Marchal (de Calvi) in 1844, of which 12 are given among 50 observations, we find 5 examples of abscess in the subperitoneal cellular tissue, 3 of subaponeurotic abscess, 1 of multiple intraperitoneal abscess, 2 of simple intraperitoneal abscess, 2 of ovarian abscess, and 3 of mixed abscess. The condition of parametric induration or abscess, especially as the broad ligament is very far from being common. The inflammations of the uterus and its appendages are all secondary, and Dr. Duncan thinks that of all prolific causes, inflammation of the mucous membrane of the womb is the most common, whether in the puerperal, or non-puerperal condition, *i. c.* of endometritis. Vilpeau thinks that diseases of the uterus may bring on abscess in the iliac region. Aran says the cause of peri-uterine inflammation are those of inflammation of the tube and ovary, which is almost constantly its starting point, and he says, "It is by inflammation of the internal membrane of the uterus, and by the propagation of this inflammation to the tube, that I explain the peri-uterine inflammations which come on in some cases, in consequence of superficial or deep cauterizations of the lips and cavity of the cervix, after the introduction of a sound, or of a replacing instrument into the cavity of the uterus, in consequence of an intra-uterine injection, of the placing of a pessary or even of a bladder of caoutchouc in the vagina, and, in some women, in consequence of sexual connection too often repeated in a given time."

---

* Metritis and Parametritis: a Practical Treatise on. By J. Matthews Duncan, Clinical Lecturer on the Diseases of Women in the Royal Infirmary, Edinburgh. Adam and Charles Black, 1869. Pp. 249.

Dr. Duncan mentions that, in many cases where intra-uterine pessaries, dilatation of the cervix by tents, and other operative procedures, have been used, he has observed distinctly ovarian swelling and tenderness precede the fixation of organ and abscess. The painful influence of endometritis is peculiarly well seen in puerperal cases and in gonorrhœal cases. In the latter cases, he has never seen pelvic inflammation come on without the presence of ovaritis in addition, and as the ovaritis follows the endometritis, so the latter is itself a consequence of the original vaginitis. West thinks that delivery, abortion, and the inflammation which follow them, stand in the etiology of periuterine inflammations for 77 in 100: and Bernutz reduces this influence to 45 in 100. Primiparæ are most subject to the complaint. In perimetritis and parametritis, of whatever kind, the affected parts almost invariably feel hard and become immovable, unless physically examined. Our author observes, the case may be regarded essentially as disease of the bladder, rectum, or nerves, many physicians being disposed to rely on symptoms, because not familiar with the results of physical diagnosis in this case. There are sometimes scarcely any symptoms, as, for example, he adduces cases of gonorrhœal ovaritis in healthy young girls, which ended in the fusion of all the parts in the pelvis into a solid immovable mass, without the patient losing any of her gaiety or complaining in any way. The papers of Bernutz, originally published in the *Archives Générales de Medecine*, will form to the future medical historian one of the chief landmarks in the history of these complaints. That author holds that perimetritis is the rule, and that parametritis is the exception in cases of tumours, around the womb. Aran, again, asserts that he has frequently witnessed cellulitis of the cellular tissue of the broad ligament. According to that observer, phlegmonous periuterine tumours present great varieties of form and volume. Some are rounded, and more or less spherical; others are oblong and flattened, but they are never large; whenever such tumours are large, the peritoneum is involved. Speaking of pelvic peritonitis of blenorrhagic or gonorrhœal origin, Bernutz says that it has never occured before the eighth day of the gonorrhœal attack, and that it is rare before the fourteenth; it has always seemed to him to be propagated by contiguity. But Aran thinks differently:

When a pelvic abscess opens externally, it generally does so in the groin, and most frequently between the internal and external inguinal openings; when it opens internally, it most frequently discharges itself through the rectum, or vagina, and more rarely through the bladder.

These abscesses not unfrequently degenerate into fistulæ. In page 164, our author mentions that, not long ago, he was called to attend a very alarming case of parametric abscess, which was the consequence of a recently performed operation for enlarging the cervical canal by metronomy. It appears to him that the fixation of the uterus which is so common a continued though not permanent result of peritoneal adhesions, can only be explained by the existence of peritoneal adhesions. We are also of the same opinion. Both medicine and surgery are unavailing in the treatment of merely adherent and fixed uterus and its appendages. Mercury and codine are not indicated, Madame Boivin is quoted as an authority by Dr. Duncan, and we hope that ere long some of our lady doctors in England or America may became equally famous. Aran mentions that of 53 autopsies of women dying in his wards, there were 29 cases in which adhesion was discovered. In page 183 an interesting case is mentioned of retroversion, complicated by adhesions, in which the lady shortly afterwards bore a child. These adhesions fortunately appear frequently to disappear rapidly, *i.c.*, in a few months.

On the head of diagnosis, our author appears to agree with Marchal that "between utro-peritoneal abscess the consequence of partial peritonitis, circumscribed abscess of the subperitoneal cellular tissue, as it ordinarily presents itself, the distinction is difficult." It is not only difficult, it is often impossible. With respect to treatment, our author does not seem to have the least faith in doses of either mercury or iodine in treating the diseases about which he writes in the work before us. He is sure they have no power to remove adhesions. Yet he sometimes uses blue pill, as an experiment, and objects to calomel and opium, because it purges, which action is injurious in perimetritis. He adds, and in this he carries us along with him, "that the use of iodine salts needs no nice clinical discrimination as that of mercury, for the drug is not in any sense a dangerous weapon, if used with the most ordinary care." This is our own view as to these two drugs as well in inflammation as in specific cases. Poultices over the whole of the lower belly are recommended. Bleeding from the os uteri by means of a *spiculum*, not a tube, is spoken well of. Four leeches are sufficient. Blistering is praised in the latter or chronic period, taking care to avoid strangury. As to opening of abscesses, when the abscess is opened internally, our author performs the operation per vaginam, by means of a common bistoury, guarded by lint rolled round it. The opening is most frequently made in the median line, just behind the cervix uteri. In operating, the right index finger follows the cutting instrument, which last is withdrawn as soon as the finger gains admission into the sac. In only one case was there much hæmorrhage, which was controlled by plugging. The abscess should be let alone as long as possibles until it is quite ripe. We recommmend all students of diseases of women to read this admirable work.

◆

THE ELEMENTS OF HEAT AND OF NON-METALLIC CHEMISTRY.

By Frederick Guthrie. J. Van Voorst, 1868.

This work is like a great number of the chemical books which have lately seen the light—written for a certain purpose. The purpose seems to be, in this instance, to provide a handbook for the Matriculation Pass Examination of the University of London. It appears to be carefully prepared, and shows considerable originality in its construction. Seventy pages, or nearly one-half of the work, is taken up with the physics appertaining to heat. This fact will no doubt militate against it as a general introductory book to the study of chemistry. It must not, however, be supposed that the author, although perhaps too diffuse for such a work on the subject of heat, has skipped over the "non-metallic chemistry" of the important elements with which he has to deal. The other 130 pages contain *multum in parvo*.

◆

LECTURES ON THE PRESERVATION OF HEALTH.

By Charles A. Cameron. London: Cassell, Petter, and Galpin. 1869.

The above twelve lectures contain an excellent popular summary of our knowledge of hygiene, somewhat in the style of Lankester's popular lectures on food. Dr. Cameron is evidently accustomed to lecture to the public, and can do so with no mean ability; but from his opening address he himself felt the incongruity of addressing ladies and gentlemen on town, who must be amused, medical students, and members of his own profession, who require something more—seeing the difficulty he evidently met it by addressing himself to the uninitiated. But, as Professor of Hygiene to the College of Surgeons, we question if this policy, looking at the end for which the chair was originated, is the best. In the second series of lectures, if they be published, we would rather see them addressed to the students; although we doubt if such a work would make as "readable" a book as that before us. The author passes in review the sanitary conditions of Jews and medicinal epidemics. The second, third, and fourth lectures are devoted to water and air. The subject of ventilation is most carefully examined. Food, ablutions, clothing, &c., are extended through two or three lectures. The author concludes by one on vital statistics and sanitary organization, and, although perhaps not the most interesting to the general reader, is certainly not the most unimportant of these lectures.

◆

Obituary.

DEATH OF MR. MAURICE COLLIS, M.B., &c.

It is with feelings of unfeigned sorrow that we have to announce to our readers the death of this distinguished surgeon, which sad and unexpected event took place on Sunday morning last, at his residence in Dublin, under circumstances of a peculiarly painful character. Upon the previous Monday morning he was performing one of those operations for which he had obtained special reputation in consequence of a brilliantly successful operation which he had performed some few years back upon the person of an esteemed fellow-citizen, whom he relieved of much deformity by excision of a huge exostosis implicating the upper jaw. Upon the present occasion the upper jaw was removed in consequence of the presence of malignant disease, and during its removal his finger was slightly abraded by a spicula of bone—so very slightly, indeed, that he did not notice the circumstance at the time. Early on Wednesday morning, however, he was seized with rigors of a most severe character, which were followed by excessive prostration. Symptoms of pyæmic poisoning then presented themselves, and, as already stated, death took place at an early hour on Sunday morning, within four days from the time he first took ill.

Mr. Collis's death has cast a profound gloom over our professional circles, and, indeed, over the public at large. In the full vigour of his manhood, forcing his way into the foremost ranks of his profession by the dint of earnest work and pure ability, his death, under any circumstances, would have to be deplored; but, occurring as it did, in the discharge of his professional duties, almost at a moment's notice, it comes upon us with a ten-fold increased shock, and we find difficulty in inducing ourselves to believe that it has pleased Divine Providence to visit his family with so great a calamity. The melancholy fact, however, is but too true, and all that is left for us to do is to bow our heads and say, "Thy will be done." Writing, as we do, under the first influence of the shock, we can scarcely bring ourselves to pen what is usually known as an Obituary Notice. We shall, therefore, content ourselves upon the present occasion with but mentioning a few of the leading facts in the life of one whose loss we so deeply deplore.

Mr. Maurice Collis was the son of a clergyman of the Church of England, and nephew to the late Mr. Maurice Collis, formerly Surgeon to the Meath Hospital, whose apprentice he became, and served his time within the walls of that institution at the time it could boast of such a staff as Stokes, Graves, Crampton, Wm. Henry Porter, Josiah Smyly, &c. Whilst studying for the medical profession, he also kept his term in Trinity College, where he took out his M.D. degree; and upon obtaining the license of the College of Surgeons he repaired to the Continent to visit there the most celebrated of their Schools of Medicine. Shortly after his return to Dublin he was elected one of the Surgeons to the Meath Hospital in the room of his uncle, who retired in his favour. This event occurred in 1851, and since then, up to that fatal Monday morning, no man could have discharged the duties that devolved upon him with greater earnestness and efficiency than did the subject of our memoir. Taking a deep interest in the prosperity of the Institution, most, if not all, the recent improvements which have been effected in that Hospital are due to his untiring advocacy and exertions; whilst the prestige of the Institution as a place of clinical instruction was in no small measure enhanced by his operations and lectures. With the Pathology and Treatment of Cancer his name is honourably associated by his valuable and well-known treatise upon that subject; and within the last year he had been placed upon the Court of Examiners at the Royal College of Surgeons, having previously filled the post of Examiner on Surgery in the Queen's University. An able surgeon, an educated gentleman, fast rising in the confidence of the public, it has pleased Providence that he should rest from his labours at the early age of forty-five years. His premature death leaves a gap in our professional ranks that will not be easily filled up.

◆

Medical News.

"In Vino Veritas." We might emulate the brevity of the old writer on the Natural History of the North, who headed a chapter of the "rats of Iceland," and added simply, "there are no rats in Iceland." Truly there seems to be no truth in wine, and apparently as little relish in the British palate for unsophisticated honesty in wine as in politics. It will no doubt occupy the inevitable half century for proof positive, to drive out ingrained prejudice from the British mind, but some shall, nevertheless, live to see the present generation, the subject of universal ridicule for its obstinacy and unreason in wine drinking, as the admirers of stages coaches or tenpenny postage stamps would be to our progressive selves. Every man's stomach and liver is his own, and if he stands upon his right to irritate and injure them, we do not challenge his privilege to make for himself a substantial and lasting dyspepsia, but for those who profess freedom from conventionality, it is somewhat inconsistent to insist on what they know well to be a tonic mixture of more than doubtful efficacy, instead of real wine. Doctors, journalists, excise officers, chemists and wine merchants, have been, and may yet be for years' teaching the Brition the exact relative proportions of logwood, lime, whiskey, and fusil oil, in tonic mixture, and yet, without doubting their truth, he continues his infallible mixture: four tablespoonfuls three times a day. We console ourselves with the consideration that in the end, Greek wines, Dr. Druitt, Mr. Denman, and the wine analysts of the medical journals must win the day, perhaps with a grievous slaughter of stomachs, but they will win it in the end. The pure, grateful, digestive Greek wines, rich in grape, alcohol, and in the grape salts, are already the recognised drink of invalids, and must, sooner or later, be the favourite beverage of the diner out. The public is not yet educated up to Mr. Bright's principle of free trade in adulteration, and when wine-bibbers come at last to know what they are drinking, they will cease to swallow concoctions even for the sake of their gusto. Mr. Denman, of Piccadilly, has endeavoured to teach them to know real wine for themselves, and we co-operate in his object by publishing from a recent pamphlet on "Pure wine and how to know it" his aphorisms on the subject. 1. That pure *sweet* wine is of low alcoholic strength. 2. That all perfectly fermented wine is dry, and of high alcoholic strength (rarely exceeding 26 degrees of proof spirit), and is not sweet, as all the sugar of the grape has been converted into alcohol. 3. That the addition of alcohol to wine, either before or after fermentation, renders it unwholesome, and conduces to gout and similar disorders. 4. That the greater the amount of *natural* alcohol produced in wine, the greater is the amount of body in it, as the other constituents of wine must have been produced *pari passu*, and have been existent in the grape to yield the amount of alcohol; whereas added spirit does not give body. 5. That the greatest amount of natural alcohol in wine is produced in those climates in which the grape attains the greatest perfection, and consequently contains the largest amount of sugar combined with the other ordinary constituents of the fruit. 6. That as all Port, Sherry, Maderia, Marsala, Catalonian, and Roussillon contain from 36 to 42 per cent. of spirits, they have been either checked in the fermentation by the addition of alcohol to retain the sweetness; or, after the fermentation was completed, the wine must have been sweetened and spirited to bring it up to the regulation standard. 7. That the addition of alcohol to wine renders it of less pecuniary value, as spirit costs but about 1s. 8d. per proof gallon without the duty, which is much less than the cost of wine; it therefore follows that if it was not for the excise and customs duty, spirit, the strength of ordinary port or sherry, could be sold for 2d. a bottle. Furthermore, added spirit prevents fermentation, covers defects, enables all sorts of mixtures to be made up and sold as wine, and thereby gives a fictitious character to the wine that the grape whereever grown can never produce. 8. That all natural wines, if any improvement is to be effected by age, must throw down a deposit, and thereby they become *sweeter in bottle by the elimination of their tannin, tartrates, &c.* From red wine the deposit contains tannin, which, uniting with the albuminous matter contained in the wine, forms a crust, that year by year becomes less and less, until at length it becomes so thin that it acquires the name of "beeswing." The deposit also takes the form of crystals, which will both adhere to the cork and fall to the bottom of the bottle like powdered glass. All natural wines that have been any length of time in bottle should therefore be decanted with care.

UNIVERSITY OF EDINBURGH — PROFESSORSHIP OF CHEMISTRY.

In addition to those already mentioned as candidates for this valuable chair, we understand Dr. Maxwell Simpson, of Dublin, has entered the field. Dr. Simpson was educated for the medical profession, and took the degrees of A.B. and M.B. in the University of Dublin, but instead of practising medicine he devoted himself entirely to chemistry. For some years he lectured in the Park street, and afterwards in the Ledwich School of Medicine, Dublin, and proved a most able and attractive teacher, but, finding the school work interfere with his original researches, he gave up teaching, and visited the various Continental schools of repute, where he prosecuted his work so vigorously as to obtain for himself a most distinguished position as a scientific chemist. He has embodied his researches in papers, which have been copied into the principal chemical journals, and adopted in the best systematic treatises on chemistry. The University of Dublin have given him an honorary degree of M.D. in recognition of his services to science, and the College of Physicians have elected him an Honorary Fellow, while the Royal Society have conferred on him the much esteemed F.R S.

THE VOLUNTEER REVIEW AT DOVER.

There are but two casualties reported, which, considering the number of men under arms—about 20,000—is eminently satisfactory. An Artilleyman had his arm dislocated by a fall, and a private of the 94th (regulars), is said to have fallen dead in the field from exhaustion. Of this latter we have very grave, and we trust, well founded doubts. The ambulances and the surgical staff were, we are happy to state but little required.

NOTICES TO CORRESPONDENTS.

NITROUS OXIDE IN DENTAL SURGERY.

Dear Sir,—I thank you for your notice of my inquiries as to the "nitrous oxide. The following cases may prove interesting to some of your readers:—

Some few years since a patient, one of the Coldstream Guards, was sent to me from the dispensary for the removal of a tooth. He had lost the *left* arm during the Crimean War. I extracted an upper molar (*left*). Immediately the operation was over he complained of violent pain "in his *lost* arm *down to the fingers' ends.*" I use his own parlance. The agency was very distressing to witness, and for more than two hours he remained in my room, suffering very considerably. There was no difficulty attending the removal of the tooth.

Last year I was in attendance at a charitable institution and was requested to extract an upper *left* molar for the deputy matron of the house. Some years since this person was at Croydon Station, talking to a friend, having hold of the brass handle attached to the carriage door, when suddenly, and without notice, the train was propelled, and her *left* "arm was torn out of the socket." Again I use the patient's own parlance. On removing the tooth the same result followed as in the soldier's case, *but with much more pain in the* LOST *arm*. This patient was very ill from the effects for some days after. I have since removed another tooth from this patient, with the same result immediately after the operation, but she recovered in a few hours.

I have had several cases of the nitrous oxide since I last addressed you without pain, but in most cases very alarming symptoms. One woman kicked and screamed most lustily, and all described most dreadful dreams. One case I know of in this town, where the patient is still ill from the effects of the inhalation some two weeks since. It is the practice here to administer the gas without a surgeon's presence! and in some cases by practitioners whose antecedents will not warrant their so doing.

Yours, &c.,
W. S. Whatford.

Brighton.

Mr. Eames.—Locomotor ataxy in our next.

On Cutaneous Angioneuroses, by Dr. W. D. Moore, Dub. et Cantab., received.

Dr. Alexander Lane, Bishop's Castle, is thanked for his kind note.

Inebriate Asylums.—In accordance with our promise, the second article upon this important subject will appear in our next number. Having placed ourselves in communication with the heads of several of the largest establishments in New York and elsewhere, we hope to lay before our readers some very interesting facts and statistics relative thereto.

Dr. Kidd, on Polypi of the Rectum, received with thanks. We cannot, however, comply with the author's request for insertion in our *next* number. Proof shall be forwarded to him as early as possible.

On Diseases of the Anus and Rectum, by Holmes Coote, F.R.C.S., shall appear as soon as space permits.

Dr. B. W. Richardson.—Sorry to have held over your communication so long. Unusual press of matter must be our excuse for the delay. We cannot *now* promise the insertion of any paper in a particular issue, owing to the increasing number our friends favour us with, and for which we thank them. Each contribution appears as nearly as possible in the order received. We hope to have space for yours in our next.

Dr. Thomas More-Madden.—See previous reply.

On the Treatment of Jaundice, by Prof. Thos. Hayden, received.

J. L.—The subject, selected for the Annual Prize of Five Guineas, to be competed for by Apothecaries' Apprentices, upon the First Monday and Tuesday in May, 1869, is "The Vegetables included in the British Pharmacopœia—their Natural History, Botany, Pharmaceutical Preparations, Chemical Tests, and Medicinal Doses." The examination will be held in the hall, at the hour of Two o'clock, p.m. Candidates must give one month's previous notice of their intention, by letter, to the Secretary, and bring their indentures on the day of examination.

Dr. Kelly.—Your communication, "The Influence of Constitution in Syphilitic Disease," shall receive early attention.

Street Accidents and Police Responsibilities.—A correspondent writing to us upon this subject is of opinion that some definite instructions should be given to the police how to act in cases of illness and street accidents. At the present time much uncertainty exists, and the police, being left to act upon their discretion—which, by the way, is ofttimes very faulty—delays occur, and, through delays, death frequently ensues, when immediate application to the nearest resident surgeon might save the life of the sufferer. Our correspondent ridicules the idea expressed by a juryman in a recent case, that such instructions to the police would interfere with the liberty of the subject.

ON DISEASES OF THE ANUS AND RECTUM.

By HOLMES COOTE, F.R.C.S.,
Surgeon to St. Bartholomew's Hospital.

I HAVE met with several cases of "coccydymi" in females, mostly in the better classes of life. The patient complains of intolerable pain at the end of coccyx, and extending thence to the anus, vagina, and along the thighs. Although, from want of clearer pathological knowledge in diseases of the nervous system, we call this an "hysterical" pain, it is nevertheless a source of positive suffering to the patient, preventing her sitting down for many minutes consecutively in comfort, and leading to a dull numb sensation down the thighs and legs after a few steps in walking. A lady, in all other respects in good health, was under my care some months ago, to whom the recumbent position was the only one which gave her rest and ease. The necessity of being constantly upright wearies the patient, and leads to œdema of the ankles and pain under the arch of the foot.

Mr. Hilton has done good service by directing attention to some of these cases of pain extending along the perineum and organs of generation, and by investigating more precisely their causes. Thus, a gentleman, soon after the death of Mr. Key, consulted him, complaining of pain extending from the ascending ramus of the ischium to one side of the penis. On examination, Mr. Hilton found a considerable thickening of soft parts, and a "cord-like" mass, rather bigger than whip-cord, near the ischium. It turned out that this gentleman was in the habit of sitting many hours of the day on a hard and somewhat uneven seat. Mr. Hilton applied some strong nitric acid to the part, so as to prevent the patient sitting on the diseased spot for some time, and directed him to have a hole cut in the stool so as to prevent pressure on the part altogether. Immediate relief ensued, and the patient got quite well. —("Influence of Rest," p. 234).

Another case occurred to him in 1860. A lady, aged sixty, had been aware for some considerable time of some unusual numbness and painful sensation near the left tuber-ischii and neighbouring vaginal labium. This was more especially the case when riding in her carriage or sitting in her study. Some time after she discovered, a marked enlargement on the "seat." On examination, Mr. Hilton detected an enlarged bursa on the tuberosity of the ischium. Now, he had known this lady some time, and she explained how she was accustomed to sit on a hard chair with a little table on her left hand, and she said, "As I read I am obliged to sit sideways on my left side in order to make my notes without getting up." Nitric acid was applied over the bursa; the eschar separated on the sixth day; but the habit of sitting on the thickened parts being removed, the bursa was cured by rest, and the pain, both perineal and vaginal, subsided.

In this case, however, we fail to discover any local causes whatever; the pain is more distinctly referred to the extremity of the coccyx, extending thence to the skin of the adjacent regions. All the patients whom I have seen have previously consulted an obstetrical practitioner, by whom a careful and accurate investigation of the vagina and uterus had been made, but without result; various local applications had been ordered the state of the rectum investigated; the bowels had been purged; iron, quinine, and other remedies has been given internally; yet the evil remained.

I determined to try the effects of the hypodermic injection of morphine, and on the following grounds—that after this long continuance of pain in the spot, "pain seems to beget pain." The patient's mind is ever directed to that one spot of suffering, and the idea, when once thus fixed, is difficult of removal. Accordingly, I tried the injection of one minim, wishing merely to allay pain without producing drowsiness. The effect was very marked. The pain for a time seemed banished, as if by magic, and the patient found herself able to sit and walk as formerly, when in perfect health. After a time the pain began slowly to return, when the injection was repeated, and with the same effect.

After a time, patients have provided themselves with the apparatus for injecting, and have carried it with them; but several have informed me that after the space of a few months, the pain seemed altogether to have left them, and that the use of the morphine was discontinued.

It must never be forgotten that the coccyx may be the seat of positive disease; ulceration may take place in the articulations, uniting the smaller pieces. I never met with such a case in life, but pathological specimens illustrating the fact are to be found in many museums.

◆

OBSTETRIC MEMORANDA.

By J. Waring-Curran, L.K. & Q.C.P.I., L.R.C.S.I., &c., Manchester.

The following cases, copied from hurriedly-written clinical notes, are not, I conceive, uninteresting, although they aim at nothing remarkable or unusual, nevertheless they are not devoid of practical importance.

Case I.—*Gastritis occurring at the Fifth Month of Pregnancy.*—Mrs. M., aged thirty-four years, the subject of chronic emphysema, pregnant with her third child, sought advice on January 2nd for constant vomiting and sickness.

She has been ill for three days, and complains of incessant pain over the region of the stomach, which rejects every article of food taken. She considered herself five months pregnant. Prescribed an effervescing mixture, with dilute hydrocyanic acid, and ordered her ice *ad libitum.*

The following day there appeared an aggravation of the symptoms. Pulse, 120 per minute, continuous vomiting, with a sense of sinking. Directed a blister to be applied over epigastrium, small quantities of brandy and *iced* soda water to be taken, and the medicines to be repeated.

January 4.—Pulse 140, breathing rapid, coated tongue, no sleep, and the burning sensation along œsophagus and over stomach increased. Gave directions that no food should be given by the mouth, and that an enema consisting of beef-tea, port wine, cream, and twenty drops of the liquid extract of opium should be thrown up the rectum every four hours.

January 5.—Retained the first enema twenty minutes. The second, third, and fifth came directly away, whilst the fourth remained three hours. Vomiting continues, which is chiefly acid bile. Pulse, 140. Prescribed naphtha, which the patient objected to take.

January 7.—Pulse 140. Incessant vomiting. Movements of the fœtus disturb the patient and create nausea. Has slept two hours.

January 9.—Continue the enema. No improvement. Proposed the induction of premature labour by the douche, which the patient refused to consent to, as well as her immediate relatives.

January 8, 9, and 10.—Condition of patient the same. Sustained or kept alive solely by beef-tea and port wine injections, to which I added ten drops of veratrum viride with the twenty minims of liquid ext. of opium (B. P.) each enema.

January 11.—Pulse 120. Vomiting continues, but retains the injection an hour at a time.

January 12.—Has taken a little wine and water by the mouth, which the stomach retained two hours. Has slept comfortably and quietly during the night. The veratrum controls the action of the heart and reduces the frequency of the pulse without increasing the sickness.

January 13, 14, and 15.—Vomiting induced if any fluid be taken. The injections of beef-tea, cream, and port wine continued, with the liquid ext. of opium (B. P.) increased to thirty minims, and that of the veratrum viride to fifteen.

January 16.—Condition of patient decidedly better. More hopeful. Pulse down to 112. Has slept four hours. Still afraid to chance any food by the mouth.

January 17, 18, and 19.—Patient progresses, and is now able to take and retain on the stomach some arrowroot and a little weak essence of beef, followed by pancreatine. Directed that half a dose of Dr. Dobell's pancreatine be exhibited thrice daily.

February 12.—Patient convalescent. The child is perceptible, and its movements stronger.

This is a case which lucidly demonstrates the necessity of patiently watching, and not being over-zealous in bringing on premature labour. At one stage of the case it was necessary to propose that interference, which although refused, the adoption of it would have been absolutely essential to perform, had not the more pressing symptoms yielded to the measures adopted, and a case wherein I have indisputably proven the therapeutic efficacy of veratrum and opium in the enemata in controlling the circulatory organs.

Case II.—*Puerperal Convulsions with Albuminuria—Adherent Placenta, &c.*—Pauper G., primipara, under treatment for renal dropsy, with albuminous urine, at full time, commenced labour on February 5th. Had been in labour four hours when the convulsive seizures began. The head presented naturally, but the os was rigid and unyielding. I immediately sent for the forceps and delivered her. The convulsions subsided as soon as the child was born. The placenta was adherent, and required care and patience in its removal. My friend, Dr. Pultney, took charge of the patient. In the course of the evening there was a slight return of the convulsions, which rapidly yielded to a whiff of chloroform and a mustard application to the nape of the neck, Dr. P. informed me.

A week after her confinement the uterine discharges became offensive and increased in quantity. We immediately washed out the passages by means of carbolic acid injections, which had a most salutary effect; indeed, my sole object in the recital of this case is to record the great benefit to be derived—which I have invariably found result—from the free use of carbolic acid in all cases of offensive uterine discharges, after parturition and otherwise, and its great superiority and more reliable effect in cases of leucorrhœa. The case also establishes the fact that, in puerperal convulsions, the sooner labour is produced, if it has not actually commenced, and delivery effected, the better, for the usual advocated remedies have in my hands proven futile and worthless.

February 27.—The woman is now well.

Case III.—*Puerperal Convulsions.*—On the 28th of February I was requested to attend an Irish woman who had been in labour sixteen hours, and suffering from convulsive seizures.

Upon examination, I found the head of the child at the brim, the membranes ruptured, and the os dilated to the extent of about half-a-crown. The convulsions were of a severe character and regular in their occurrence. I applied cold to the spine, as advised by my distinguished friend, Dr. Chapman, of London, and had recourse to the other ordinary methods to arrest them, but without success. Having waited for a little time I found the advance of the labour to be slow—yet Sir J. Simpson advises, when any progress is being made, interference is to be avoided, nevertheless, acting on the golden rule that the urgency and similarity of no two cases are alike, I was guided by the symptoms, and on consulting with Dr. Clegg, applied and delivered by the forceps.

The child I brought into the world living, there was one faint return of the seizures, but the woman rapidly recovered, without a bad symptom.

This is a case which demonstrates the necessity of interference, when the practitioner desires to save the lives of both mother and child, and not to be bound to any rule or opinion, however eminent the source from which it originates or emanates. This I say with all respect to the eminent authority whose name I have taken the liberty to associate with what I conceive to be a fallacious rule, which I understand Sir J. Simpson to be author of.

Case IV. — *Funis Presentation.* — Pauper Bamford, twenty-four years of age, had been under treatment for condylomata and snail track ulceration of throat at the seventh month of her pregnancy.

On February 7th labour began, the funis presented, and was followed by the placenta. Delivery was hastened and completed, the child of course being dead. There were most fœtid and highly offensive discharges from the commencement. Carbolic acid injections were immediately prescribed. Under their use recovery was effected in a much shorter space of time than I have ever before experienced in a similar class of patients; indeed, I am actuated in stating that carbolic acid injections, in cases of discharges from the uterus or vaginal tube, set up healthy action, not only more quickly, but more agreeably to the patient than any other form of injection hitherto employed by me in practice, or witnessed in the practice of our obstetric institutions by the distinguished attendants attached to them.

◆

ON INFANTICIDE AND ABORTION AS *SUGGESTED* INSTITUTIONS.

By Ewing Whittle, M.D., M.R.I.A.,

Lecturer on Medical Jurisprudence and Toxicology to the Liverpool Royal Infirmary School of Medicine.

(Continued from page 265.)

Several sections are then devoted to the working out of the proposed details of the system. Then follows another chapter, which is marked as "Printed for private circulation."

Here Marcus says—"Let us now contemplate the stifling of a just born infant, and let us separate the various elements which concur to arouse within us a sense of horror and reluctance. They are these: the parent regrets a loss; he shrinks from the infliction of a pang. Of these two feelings we may nullify the one, we may compensate the other. After disposing of the compensation Marcus proceeds to the nullifying. "Next, for the feelings of compassion we will provide by making the infant to be happy, if he live; if not, to be unpained in the act of dying. This the great and difficult problem to remove altogether the idea of pain inflicted, an idea which makes the principal difference between the killed and to die." Quite as much tender sentiment as if the gentleman was discussing the drowning of a litter of puppies or kittens. Again:—

"Beyond these two considerations, there is another which goes to make up the complex idea of criminally killing. It is that of the right of prosperity in life inherent in the living person himself."

"It can be clearly demonstrated that he never can have possessed the right, any more than he has felt the wish to live."

"He has not a real right to live, because it has never been given, bequeathed, or conferred in any legal way, or by any principle of natural justice equivalent to formal legality. The child's pretensions to any mundane existence, being thus summarily disposed of by such arguments for their apothesis as little innocent angels. Let their be a repository for the privileged remains of these infants not admitted into life. Let it have nothing funereal about it, but all that is cheerful and agreeable. Imagine a colonnade, closed and gently warmed in the winter, fresh in summer, verdant always, yet not expensive in exotics; not too distant for the daily disport of all classes, yet silencing vulgarity by an amiable and religious formality. Let this be the infant's paradise; every paturient female will be considered as enlarging or embellishing it. This field of fancy will amuse her confinement, and she will be pleased by the reflection that her labour will have been not in vain, and that even posterity are to be the better for it."

The final chapter is headed—

"*The Theory of Painless Extinction.*"

This chapter is devoted to teaching how infants can be put to death without pain, by gradual submersion in hot water, or by the use of carbonic acid gas, to this lesson in murder several pages are devoted, from this I cull a few passages. At any rate we need not fear that it is stifled in the usual sense of that word, for the external appearances are different, stifling is quick, sudden and violent; this quite the reverse, a difference alone sufficient; let us reascend to causes, and we shall find that the cause of the phenomenon understood by *asphyxy by stifling*, is no other than the urgent impatience of the appetite for air. Now that the appetite has not, in our new-born animal yet acquired the fully-formed sensibility, or become susceptible of impatience—no pang is felt, for no sensation is shocked—instead of growing quickly towards full formation, it decreases; instead of being awakened it is dulled. It and the uneasiness along with it slowly perish away and disappear. But enough of this vile and despicable trash which it would be a waste of time to call your attention to, if we did not find it again cropping up in high quarters after an interval of thirty years. Of recent authors of note who fully endorse Malthus' views, I may mention Nassau, Senior, Whately and Mill. I quote from Mill; "Little improvement can be expected in morality until the producing of large families is regarded with the same feelings as drunkenness or any other physical excess." "But while the aristocracy and clergy are foremost to set the example of this kind of incontinence, what can be expected from the poor?"

Does this philosopher, who would remodel the moral laws that govern mankind, reflect for a moment on what would be the inevitable result of a number of married couples attempting to live up to his idea of continence: I will venture to affirm that the number of births would in no respect diminish; and that in fact the fell expedient of Marcus rather recommends itself as having at least the merit of solving the difficulty with a vengeance. The practice of inducing abortion has not been openly recommended by any of these authors; Marcus hints at it approvingly. Lord Amberley compliments the American ladies on their keeping down their families, though faintly objecting to their practice of abortion. It is rather the business of the sound political economist, than of the medical man to pursue the line of argument, which would prove how greatly Malthus and his followers have been deceived, and how groundless are the premises on which they have based their deductions, and how very far the Creator was from intending that the progress of man should be governed by the infamous laws imputed to him by Malthus, in these words, "vice and misery are necessary agents in God's government of the universe, and without the agency of vice and misery, God's government could not go on."

The opponents of Malthus, with more or less success, endeavoured to show that his fear of over population was merely a bugbear of his own imagination, that the fruitful teaming earth was ever ready to pour into man's lap an over abundance, in return for his industry bestowed upon it; that, in those exceptional cases where want existed, the cause was due to the evils of monopoly, or injudicious legislation, which cramped the energy of the people; but no triumphant reply was given to the plausible theories of Malthus, until the subject was taken up by a man of genius, the late Thos. Doubleday, who, in his great work on Population, has refuted in a most able manner the Malthusian theories. His work was published in 1841, it is entitled "The True Theory of Population shown to be connected with the Food of the People."

He places appropriately on his title page a passage from Exodus, "But the more they afflicted them, the more they multiplied and grew." The principle which the author endeavours to establish is this : "that in nature a general law exists for the protection of species, whereby fecundity is stimulated by a condition of Depletion, and checked by a condition of Repletion ; that this law applies equally to the vegetable and the animal kingdom ; that as applied to man, this law produces the following results :—That in all societies a constant increase is going on amongst the worst fed, that is, the poorest part of the people ; that amongst the affluent, who are well supplied with food and luxuries, a constant decrease goes on ; amongst those in a medium state, who are tolerably well fed, not overworked, and yet not idle, population is stationary. In a nation where the affluence is sufficient to balance, by the decrease which it causes amongst the rich, the increase arising from the poor, population will be stationary. In a nation highly and generally affluent and luxurious, population will decrease and decay. In poor and ill-fed communities population will increase in the ratio of the poverty. This is the real and great law of human population."

The author then adduces a variety of facts referring to the vegetable kingdom ; then to the animal creation, and ending with the human world, the numbers composing which he shows to have ebbed and flowed as one or other of the different states he has described prevailed more or less : he then argues (and I think with great success) to show that his theory has not only a wonderful agreement with the state of the world as it is known to exist and to have existed, but also its admirable unison with the wisdom and goodness of that Divine Providence, which " saw all that He had made," and saw that all was *very good*, until marred by the wickedness or folly, the error or ignorance of man.

Doubleday takes his first illustrations from the vegetable kingdom : he cites the facts that are familiar to all horticulturists, that if trees or plants are over stimulated by manure they run, trees and shrubs to leaf and wood, and do not bear fruit, while flowers become double and cease to bear seed. Turning to animals he cites the experience of breeders, that over-fed animals never breed well ; and hens if over-fed will not lay well. To Doubleday's illustrations, I would add one from the natural history of the bee.

It was discovered by Huber that when bees are deprived of their queen, they take a common worker grub, treat it as they do the queen grub, feed the pupa with the food of the queen pupa, and the worker becomes developed into a queen, the workers or neuter bees, being all females, with imperfectly developed sexual organs, feeding with a particular food furthers the development of these organs, and the procreative power is established in the insect.

After these preliminary observations the greater part of the volume is devoted to the proof that the same law applies to the increase and decrease of the human species ; to prove this he makes reference to the statistics of many countries, to the statements in the writings of ancient authors, and to proofs derived from the extinction of families in limited societies. He first states the facts which are indisputable, that in the present day, in pastoral countries where the food of the people is principally animal, the population is invariably thin, *denser* where the food is partially vegetable ; *denser* still where it is vegetable only, but with plenty, and most dense where it is vegetable with scarcity superadded.

In Poland, France, Italy, and Belgium, where the diet is mixed but plentiful, population is moderately dense.

In India, Ireland, and China, where scarcely any animal food is eaten, where the vine and the olive are absent, the population is excessively dense, and constant pauperism and periodical famines form decided features in the history of these countries. Sismondi in his Political Economy observes, " The slowness in the increase of a population is most frequently an indication of great prosperity ;" he then mentions Geneva as an instance of this prosperity : " in that city the number of births to a marriage is rather less than three, two of whom replace the father and mother and the other one or *minus one* represents those who do not reach the age of marriage or who die in celiebacy." He adds, " There is no danger here of that subdivision of property with which we are constantly menaced by the English economists." Here we have the beau-deal of a limited population as sought to be arrived at by abortion and murder, by the philosophers of the Malthus and Marcus school. He then cites Ireland as the very opposite to Geneva, and contrasts the great increase of the poor Catholic as compared with the well-to-do Protestant population. I will now proceed to cite some instances of the working of this law among limited bodies of men.

1. The Peers and Baronets of Great Britain.—Of all the Peers nearly three-fourths are creations since the accession of George III. Since the first creation of Baronets in 1611, seven hundred and fifty-three Baronetcies have become extinct. Of all James I. creations only 39 remain.

2. Venice.—Addison says, of the Venetian nobility, Amelot reckoned in his time 2,500 nobles who had voices in the Council, but at present there are not more than 1,500, notwithstanding the addition of many new families since that time.

3. Berne.—Malthus gives this account of the bourgeoisie of this city. From the year 1583 to 1654, the Sovereign Council admitted into the Bourgeoisie 487 families, of which in 1783, two centuries after, only 108 remained.

4. Ancient Rome.—He quotes from Tacitus, " Iisdem diebus in numerum Patriciorum adscivit Cæsar vetustissimum quemque e Senatu, aut quibus clari parentes fuerant. Paucis jaum reliquis familiarum quas Romulus majorum, et Lucius Brutus minorum gentium appellaverat ; exhaustis etiam quas Dictators Cæsar, lege Cassia et Princeps Augustus lege Sænia sublegere."

5. The Free English Boroughs.—Mr. Doubleday shows that, notwithstanding the advantages enjoyed by free burgesses from the wealth of their corporations and their commercial monopolies, and the fact that the sons of freemen were always free, still their numbers were only kept up by the constant influx of apprentices. He maintains this proposition by carefully prepared statistics taken from many boroughs.

The opposite view that the deplethoric state stimulates population is illustrated by many examples :

1. Pitcairn Island.—The mutineers in about 40 years on this barren island increased in numbers nearly tenfold ; though their lives were a constant struggle to procure food, having hardly anything to live upon except yams and fish.

2. The Western Highlands.—Report by Sir John Macneill in 1851. He gives a most instructive comparison between twenty-seven poverty-stricken parishes in the West, and twenty-seven self-supporting prosperous parishes in the Eastern Highlands ; he shows that in the latter, during fifty years the population had decreased 29 per cent., while in the poverty-stricken parishes it had increased 126 per cent.

3. The constant increase of population in the little barren island of Malta.

4. The great increase of the Helots in ancient Laconia, while their Spartan masters so diminished that, according to Niebuhr, there were only about 700 left, 250 years B.C.

These are but a few of the arguments advanced by Doubleday in support of his theory, and I think I have set before you quite enough to satisfy you all that at least the question of the Law of Population is still *sub judice*, and that the Malthusians are bound to advance stronger arguments than they have hitherto done, in favour of their views, and to endeavour, if they can, to refute the mass of evidence which Doubleday has brought forward, evidence which goes far towards proving, if it does not absolutely decide, that the premises on which their theories are founded are utterly baseless ; that the theories themselves are mere bugbears conjured up in the imagination of superficial dreamers. But I will not detain you further on this part of the subject, which belongs more especially to the domain of the political economist. Having set before you the present aspect of this disputed point, I turn to consider it now in its relation to our art; feeling that we are more particularly called on to take up the subject as the false prophets have thrown down the gauntlet before us, insolently calling upon us to abet them in their wild crusade against nature. Let us not be slow to accept their challenge; let us proclaim loudly that medicine is not the science of the day that points out the way to infidelity and to vice; that she, with us her votaries attending, is ever the patient handmaid of nature, ever ready to further her efforts for the good of mankind, and always regarding with horror and disgust any unnatural attempts that are sometimes made to mar her purposes. We may cast in their teeth the words of the Pagan moralist, more virtuous than our philosophers of the nineteenth century: "*Naturam expellas furcâ, tamen usque recurret*," and fierce would be the reaction when nature reasserted herself, if even a partial success were permitted to these designing men in their infamous attempts to mar her fairest works, to arrest the progress of the human race, to exalt murder into an institution, and to substitute a scheme engendered in their obscene imaginations, for the moral government of the God of Nature. If I express myself sternly on this subject, I do so the rather that some medical men have been weak enough to give a degree of countenance to these theorists, therefore I think as a profession we are the more called upon, to declare our abhorrence at their unnatural projects, and turning with disdain from the mad schemes of Malthus and Marcus, upheld though they be by the genius of a Whateley, the intellect of a Mill, or the social influence of a Russell or an Amberley, to assure the whole host of false philosophers that as cultivators of the godlike art which we profess, we shall ever, as our predecessors have done from time immemorial, walk truthfully and reverently in the footsteps of nature, and that under no circumstances will we ever be parties to any attempt to limit the natural increase of our species, whether by taking the lives of those whom they assume to be born as a superfluous number, or by any prurient interference with the legitimate intercourse of the sexes, seek to keep the number of live births within a stated limit.

Hospital Reports.

METROPOLITAN FREE HOSPITAL AND FARRINGDON DISPENSARY.

CASES OF SYPHILIS TREATED WITHOUT MERCURY.

By Charles R. Drysdale, M.D., M.R.C.P., F.R.C.S.,

AND

Robert W. Dunn, Esq., M.R.C.S.,

A part of which was read at the Harveian Society on March 18, 1869.

(Continued from page 268.)

Case 7.—John D., aged nineteen, seen December, 1866, by Mr. Dunn, with sore on the foreskin, slightly indurated. Lotio zinci sulphatis. Glands in groin indurated. January 22nd. Ulcerated sore throat, with large ulcer on left tonsil. Touched ulcer with nitrate of silver, and patient to take the chlorate of potash mixture t. d.; syphilitic roseola appearing. February 14, 1867. Throat still sore; rash fading. March 24th. Rash gone; *repete medicinam.* May 10th. Slight alopecia syphilitica. May 13th. Iritis. To take five grains of iodide of potassium t. d., and drop a solution of atropine (gr. ij., aq. ℥j.) into the eye twice daily. 30th. Iritis disappeared; continue. June 14th. Discharged well. No relapse in 1868.

In some cases the whole of the disease apparently consists almost entirely in a few mucous tubercles, and appears but slightly to affect the general health.

The following cases are examples of this kind:—

Case 8.—Eliza M., nineteen, was treated by Dr. Drysdale from 19th May to 10th June, 1864, for slight sore throat and mucous tubercles on the vulva, which latter, on being occasionally touched by strong nitric acid, soon disappeared. This patient was observed for many months subsequently, and no further symptom was noticed. In 1868 she was in good health.

Case 9.—This was an equally slight case. Catherine H., aged twenty, seen first November 7th, 1864, with mucous tubercles on the vulva and the same affection between the toes. On being touched with nitric acid these affections soon disappeared, and although the patient continued to attend for nearly a year afterwards, to report herself, no further symptoms were seen.

Syphilitic iritis requires no mercurial treatment. It almost invariably gets well in about three weeks, without injury to the eye.

The following cases will illustrate this remark:—

Case 10.—George W., aged eighteen, with iritis, roseola, and mucous tubercles on scrotum. The iritis subsided in about three weeks, and vision was entirely restored. The mucous tubercles, touched with nitric acid, soon disappeared. The patient was under treatment from March 27th until May 16th, 1865. No relapse in 1867.

Case 11.—Miss G., aged twenty-one. February 11th, 1868. During the past week her left eye has been inflamed, and there has been pain in left frontal region, with slight intolerance of light. There is muddy appearance of the iris, and triangular pupil. Syphilitic psoriasis on arms and thighs. Infection apparently about nine months previously. Treatment—To drop in a solution of sulphate of atropine (gr. ij. aq. ℥j.) twice a day into the eye affected. The iritis subsided in about three weeks, and shortly afterwards vision was excellent. No relapse in 1868.

Case 12.—Edward D., aged twenty-five, seen by Mr. Dunn March 8th, 1866, with gonorrhœa, swelling of penis, and inguinal glands on both sides enlarged. Connection February 25th, 1866. The foreskin could not be retracted. March 21st. Indurated lump on the foreskin. March 24th. Scaly syphilitic eruption with sore throat. To take chlorate of potash mixture and gargle with chlorate of potash. March 27th. Universal syphilitic eruption over the body. *Repete medicinam.* June 10th. Mucous tubercles on lips; psoriasis of tongue; rash faded. Repeat. August. Much better; rash gone. Sent to Harrogate. October. Well. No relapse since that date.

Case 13.—Henry M., aged twenty-two, seen by Mr. Dunn in May, 1866, with sore on the frænum, and inguinal glands on both sides much enlarged. To take chlorate of potash mixture. June 14th. Left, sore being healed. In July returned with syphilitic roseola and alopecia. To take ten drops of tincture of the perchloride of iron t. d. In August he was much better. The mucous tubercles on the lips still continued. September 24th. No symptoms. No relapse in 1868.

Certain syphilitic affections require the employment of iodide of potassium, and in such cases the use of large doses of the salt has in the author's experience proved most rapid in effecting a cure. For example, John J., aged thirty, was seen at the Metropolitan Free Hospital, 13th Mar., 1868, with deeply ulcerated sore-throat, extending far down on the left side of the pharynx. The patient on being questioned, remembered having had gonorrhœa nine years before, and some slight eruption and sore-throat about that time, and slight tendency to sore-throat ever since. The ulcer in the pharynx was very extensive, covered with a quantity of mucus, and extending down as far as the eye could see, on depressing the tongue. The patient's appetite was very bad, and he was rather emaciated; although evidently a strong labouring man. The throat was touched freely with nitric acid, and twenty grains of iodide of potassium were ordered in two fluid ounces of water t.d.

The very next note taken on March 20th, shows that the patient considered his throat as "quite well," "He could eat any mortal thing." The parts soon became quite cicatrised.

Syphilitic sarcocele, when occurring in patients not hitherto treated with mercury, yields very rapidly to large doses of the iodide of potassum. John W., æt. twenty-seven was seen March 6th, 1868, by Dr. Drysdale, at the Metropolitan Free Hospital. Two years previously he had suffered from a hard sore on the penis, alopecia, and slight eruptions on the skin; but did not appear to have been treated for these symptoms, which, indeed, were all rather slight and transient. When seen, the left testicle was found much enlarged, the size of a man's fist, and very hard. Patient was ordered to take twenty grains of iodide of potassium in a wine glassful of water thrice daily. In a month the testis was of natural size and consistence.

The same lesion occurring in the person of a young gentleman, a relation of Dr. Drysdales', who had taken no mercury for a slightly indurated sore, followed by spots of a rupial character, was rapidly relieved by large doses of iodide of potassium; in about fourteen days, the organ returned to its proper size and consistence.

Ozæna, also, with destruction of the bone, is in most cases rapidly stayed, and cured by the administration of twenty grain doses of iodide of potassium. For example, Amelia M., æt. fifty-two, was seen 12th May, 1868, with ozæna of the right nostril, and dead bone; and with ulcers of the right tonsil. Patient said that, nearly twenty years ago, she remembered to have experienced some symptoms during her married life. The husband had been dead sixteen years, and she had neither had any children, nor miscarriages. Under large doses of the iodide, the patient's health became greatly benefited, the ozæna stopped, and pieces of dead bone came away.

Iodide of potassium, however, has only the power to cure the existing symptoms, not to cure the disease. An example of this is seen in a case of a woman, who for six years has attended the dispensary with a large scar on the left thigh. This scar occasionally breaks down, and becomes an ulcer, which is at once cured by the iodide, again to relapse in a few months. The woman's health is good and she has healthy children. The affection named syphilitic psoriasis of the tongue appears not to be very amenable to treatment; but it is consoling to be aware that persons may retain this lesion for twenty years, and have no other symptom, and procreate healthy offspring.

For example, Mrs. M., aged fifty-five, was seen February 18, 1868, at the Metropolitan Free Hospital. Her tongue was covered with white patches, and the edges were indented by the marks of the lower incisors. Patient had been married once, thirty-four years before, and had had five children, only one of whom was alive at that time, aged twenty-eight. Before his birth she had one still-born child, twelve months after marriage. Her tongue had been affected in this fashion for many years. No amount of iodide of potassium did this case any good, and we presume our friends who employ mercury have like experiences, at least some of the most eminent among them have confessed as much to us.

Mary S., married in 1838; seen 1st March, 1868. Had two children, both of which died; the first was born seven years after marriage. When pregnant, she suffered from sore throat and eruption, and the child had eruption and was treated at Blackfriars Bridge Hospital with powders and died. A year subsequently another child was born, which had eruptions, took powders, and died in nine weeks. Her husband died in America. He and the patient were both treated by Mr. Paget at St. Bartholomew's Hospital, when she took a great deal of medicine, and was in-patient. At the date of first seeing her, patient had extensive psoriasis of the tongue, which, in spite of large doses of iodide, still remains, although the salt improves her appetite and "does her a great deal of good."

(*To be continued.*)

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. Thornley Stoker, M.D., L.R.C.S.,
Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

MERCER'S HOSPITAL.

Locomotor Ataxy.

(Under the care of Dr. Eames.)

Caromelo Giagoloni, an Italian sailor, aged thirty-one years, unmarried, was admitted into Mercer's Hospital February 28th. During his childhood he suffered from some affection of the lower extremities, of which he could not give a very clear account. Since that period he enjoyed perfect health till four years ago. His relations are all healthy, and have never exhibited any symptoms of neurotic disease. He has never had any venereal complaint. On a voyage to Constantinople, in the year 1864, he was much exposed to wet. He now became subject to severe flying pains in the lower extremities, which came and passed away with the rapidity of lightning. He suffered, too, at this period from occasional impairment of vision, diplopia, and amplyopia, also from deafness; these would last from twelve to twenty-four hours, and recurred about once a fortnight. His feet became numbed at this time, and he experienced some consequent difficulty in locomotion. The sexual powers were at this period exaggerated, being able to have connexion seven and eight times a night. He improved in general condition, and made a voyage to the Sea of Azov, where he suffered severely from cold, whilst wintering there. On his return he was admitted into an hospital at Marseilles, being unable to walk without reeling. He was there treated by tonics and electricity.

From the account which he gives of the examination made by the physician, there is no doubt locomotor ataxy was diagnosed. Having been under treatment for two months, he left hospital much improved. He next made a voyage to Dublin, and immediately, on his arrival in port, was sent to Mercer's Hospital. He complained, on admission, of pain in the abdomen. On inquiry it was found that his bowels had not been moved for five days, and that he had not passed water for twenty-four hours. The urine was drawn off and the bowels freed by a purgative enema. During the remainder of his stay in hospital he passed water freely, and his bowels were moved regularly. He now directed our attention to his troubles in locomotion. On being directed to leave his bed, he at once and without difficulty did so, but before commencing to walk he pressed his feet with his hands against the floor of the ward, for the purpose, as he said, of insuring perfect contact, as he had lost all sensation in his feet. On attempting to walk he reeled and staggered, and could not proceed unless clutching by the bedsteads or guided by some of those present. He was quite unable to support himself with his feet placed parallel to each other if directed to look upwards or to shut his eyes. He could stand in this position if allowed to fix his eyes upon his feet. The muscular force of the limbs was at the same time perfect, as the patient was able to carry on his back one of the pupils present, if held by the hands. On his returning to bed we proceeded to examine the limbs as regarded the anæsthesia of which he complained.

On tickling the soles of the feet there was no motion whatever of the limbs, nor was the tickling felt in the slightest degree. We next passed a pin more than a quarter of an inch in depth into various parts of both feet. Neither was this felt, the patient regarding our operations with a placid smile, and saying "pas de tout." The same is true as to the entire anterior aspect of the leg. But over the gastrocnemii on both sides sensation was perfect, nor had it ever been impaired in these situations. Above the knee sensation was perfect. He mentions that he suffers slightly from spermatorrhœa and also occasional incontinence of urine, He has lost all sexual power not having had an erection of the penis for two years. He also suffers from time to time from vertigo. Has never noticed squinting or dropping of the eyelid. He distinguishes perfectly between heat and cold applied to the feet.

The treatment adopted was syr. of the phosphate of iron in ʒj. doses three times a day, the passing of the interrupted magneto-electric current along the limbs, and full nourishing diet. Under the use of these his condition improved, and he was able to walk with greater confidence. As his ship returned to Italy in a fortnight he was obliged to leave hospital. He was then able to walk without actually reeling, but his gait was precipitant, whilst the trunk was bent forward. Sensation had returned below and in front of the internal maleolus on each foot, and he himself attributed the fact of his being able to walk more securely with his boots on than in his bare feet to the fact that he felt his steps when his boots were on, but not at other times. He had also lost to some extent the numbness in his knee-joints. His condition otherwise was unchanged.

This case is interesting as exhibiting in a marked degree the initiatory symptoms of the disease known as locomotor ataxy. The burning pains, flying like an electric spark through the limbs, the passing derangements of vision, the transitory deafness, and the increase of virile power, to be followed, by-and-by, by its total loss. It shows, too, to how large an extent the troubles of locomotion depend on the anæsthesia of the feet, and the temporary, but decided, improvement in the condition of the patient which follows upon even partial restoration of the cutaneous sensibility.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

MARCH 22ND, 1869.

PETER MARSHALL, ESQ., President, in the Chair.

Mr. **SPENCER WATSON** exhibited two cases of

INTERSTITIAL KERATITIS, OR PARENCHYMATON INFLAMMATION OF THE CORNEA—NO MALFORMATION OF THE TEETH WAS MANIFEST.

The first case seemed to Mr. Watson to be one of those generally associated with constitutional syphilis. The mother has had three children still-born, and discoloured at birth. The treatment consisted of hydri cretâ and iodide of iron; pain in the knee-joint came on after the administration of the mercury; which rheumatic pain sometimes throws light on these cases. In irritable constitutions, Mr. Watson recommends the tonic treatment, and cod-liver oil, the pupils to be kept well dilated by atropine.

Mr. **HOGG** said that these kind of cases are met with in large numbers, and as a rule are very difficult to treat. He considers them of the superficial kind of inflammation, and differing much from the cases related by Mr. Hutchinson, which are of a rarer kind. In the latter you frequently get synechia and obliteration of pupil as after consequences.

In reply, Mr. **WATSON** differed most completely from Mr. Hogg in his opinion of the two cases. He considered that in *both* the parenchyma was inflamed. He had omitted one fact, namely, that the urine was highly acid.

Mr. **DUNN** related a case where a patient of his had contracted syphilis within a month of pregnancy. On January 12th, she was confined; on March 14th, the baby began to snuffle; and a rash appeared on the nates, face, and skin; There were also mucous tubercles on the corner of the mouth. Most authors deny that syphilis contracted by the mother in the last month of pregnancy can be communicated to the offspring; this is the first case on record.

Mr. **WEEDEN** considered the evidence not quite sufficient to establish the case.

Mr. **DUNN** stated that the man and his wife had never before had syphilis, the first appearance of it in the man being in November.

Mr. **HOGG** explained the difficulty there was at arriving at conclusions in these cases.

Mr. **HAMILTON** also considered the transmission of the recent syphilitic attack from the mother to the child not already established.

In reply, Mr. **DUNN** said that secondary syphilis showed itself in the second and third months, and not in the first.

Dr. **THOMPSON DICKSON** then read an abstract of his paper on matter and force, considered in relation to mental and cerebral phenomena. Our ideas are vital phenomena; the resultants of motion conveyed through nerves from external objects. The immediate phenomena are chemical and physical changes in the brain cell, or cells with which these nerves are connected; agitation or vibration of that cell or cells which is communicated to other cells, evidenced by a succession of impressions related to the antecedents, and suggested by it. The evidence of the physical change is the permanence of the impression. We see a rose for instance, its image fades from mental view on removal, but its impression remains, a permanent change in a cell or cells which becomes prominent whenever the cell or cells are rendered active, and we appreciate the comparative difference from other cells. Music is an illustration; music is a modification of motion reaching our aural sense organs as waves, varying in rapidity, and known as hearing, one factor of which is the permanent impression of the musical sound. The evidence afforded by diseased condition is very characteristic, especially when compared with pathological changes as seen after death, we observe various forms of imperfection in mental phenomena, as loss of memory, incoherence, &c.; and we find associated therewith, atonic, atrophied, amyloid and fatty cells; and, as a current of electricity will not pass through a glass rod connecting two portions of copper-wire, those cells which are unhealthy, or have foreign matter in them, cut off the current which should otherwise pass between two portions of brain connected by them, the current on the other hand running in the course of the greatest vitality. Morbid speech is often strongly confirmatory, the current being unable to pass to the cell bearing the impression of the word which should follow in logical sequence, darts off to its antithesis. Many such cases are followed by epilepsy, or cerebral hæmorrhage. I shall only touch upon epilepsy, which appears in two forms; one in which the muscular phenomena are violent, while the mental are more or less slight; the other in which the mental phenomena are profound, while the muscular are more or less absent. Observation has led me to the conclusion, that in health there is a perfect balance between the controlling organs of the brain and the muscular system. In the latter form of epilepsy, the whole surface of the brain is more or less changed; while in the former, a part only has been injured, and that perhaps by coarse disease as tumour, in which case a portion of the seat of control over the motor centres is destroyed. In passive conditions we shall not have any manifestation till the potential energy (or specific power) will so overbalance that of the seat of control, that it will extend itself in violent contraction, till its potential energy again approximates the balance of that of the controlling seat.

DUBLIN OBSTETRICAL SOCIETY.

Dr. **EVORY KENNEDY** read a paper on

PUERPERAL FEVER,

in which he wished to direct the attention of the Society principally to the question of the preventibility of the disease; and for that purpose he commenced by accepting the doctrine that it is essentially a zymotic affection, and proceeded to show that, according to the statistics of London and other great English cities, the mortality from zymotic diseases alone is between one-fourth and one-fifth of the gross total of deaths. Further, that in nine out of ten cases death, in such instances, results from preventible causes; hence that the mortality may be reduced one-fourth, minus one-tenth.

Although the difficulties surrounding the actual detection of the miasm or germ which generates this class of diseases has yet to be overcome, still there can be no doubt of its existence as an entity; and we can investigate the laws which govern its development with much accuracy, and know and can handle many solids which may be said to contain, if not the poison, at least its habitat.

He thought that the view that a common principle, modified in its forms of manifestation by surrounding circumstances, was the root of various forms of zymotic disease, was indicated by the concurrent prevalence of different zymotic affections, and that it was strengthened by the possibility of tracing various manifestations of disease to a common germ. Thus, hospital physicians are well aware of the increased likelihood of the occurrence of metria during the prevalence of typhus, scarlatina, or erysipelas. This occurrence has now been so often observed that there can be no doubt that such phenomena stand in the relation of cause and effect. He had treated so fully of this subject in a paper read before the British Medical Association, that he would now abstain from going into it *in extenso*. Should the principle of isomerism—which of late had attracted so much attention amongst our chemists and professors of physical science—be adopted in disease, it would much simplify the difficulty which we now feel in accepting the theory of a common morbific poison; and in that case we might bestow on the polyatomic molecule or principle the name of *zymotocene*, and it would strictly fall within Dumas' definition of what he terms polymorphism. There is, therefore, nothing unreasonable in supposing that, as in the case of polymeric or polymorphous hydrocarbons, we may also have the germs of different disease produced by polymeric combinations in the same elements.

Puerperal fever appears epidemically, being most virulent in crowded maternities, but also visiting the chambers of the rich and the hovels of the poor; and of its contagious character now-a-days no doubt is entertained, although he (Dr. K.) stated that, twenty years ago, the advocate of contagion was regarded as worse than an infidel. If the views arrived at with regard to the true nature of the poisoning in these cases be correct, then the contagious and sporadic nature of the disease will be quite reconcilable. Its local cause approaches more nearly to a *constant* quantity in the wards of a lying-in hospital, whereas it is only an *occasional* quantity in the houses of the affluent; and the only influence exercised in its production by the atmosphere is, that in certain states of the atmosphere the *constant* and *occasional* quantities become more operative. The poison is more concentrated in the case of numbers, but can be fully generated by one parturient woman. The most striking parallels that we are acquainted with are—the gaol fever, erysipelas, cholera, and tuberculosis occurring amongst the crowded labourers in large cities.

In distinguishing between metria and its congeners, it would be unnecessary for him to dwell upon after-pains, Hysteralgia, or what he used to term Peritodynia, or Gastralgia; but peritonitis and metritis might require a passing notice. These affections, occurring apart from the puerperal state, are sometimes met with, but then they do not assume the zymotic form, but seem purely local inflammations. These are the class of cases in which he would advise the free use of the lancet and of leeches, where twelve or eighteen ounces of blood taken by the former, and followed by the application of eighteen or two dozen of the latter, would subdue inflammatory symptoms, and change the character of the previously incompressible pulse. He would distinguish between this form of disease and true zymotic metria by the symptoms of blood poisoning which occur in the latter—the shrunken features and the unmistakeable expression of countenance. In the zymotic puerperal fever the lancet could rarely be used, we must depend on local depletion; and the true secret of success is to reduce the pain by repetition of leeching, before reaction has time to establish itself. He has seen patients repeatedly lost owing to the hesitation of a physician in persisting in the use of leeches where he had found them to subdue pain. Another practical hint which he would wish to impress upon his hearers was the value of the use of mercury in these diseases, if its effects could be produced; but in bad cases there was no time to get the patient under its influence. Therefore, in his own practice, it was his custom, where he dreaded the advent of metria or peritonitis, to commence the use of small doses of grey powder as soon as the labour was completed; in some suspicious cases even using mercurial inunction. In this way he was enabled, if bad symptoms manifested themselves, to speedily mercurialise the woman. He had but on one or two occasions seen death occur where the mercury showed itself. In the treatment of metria there are two indications—the relief of local symptoms, and the support of the constitution by nourishing and easily assimilated food. We should remember that, although local depletion is necessary, yet that metria is a *poison fever*—a disease of debility—and that if we neglect to support the strength, the patient will sink from the collapse which must ensue. Stimulants must be used more guardedly, but, as a rule, they were not used soon enough; and in one instance in particular, in a class of cases which he had described many years ago, which were marked by sudden collapse, exhaustion, and tympanitis, and were allied to what Laennec had termed "Factitie Debile," it is surprising the quantity of stimulants which can be borne. It is in this class of cases that the turpentine treatment is so valuable, and it is remarkable the slight appearances of disease which a *post-mortem* examination will reveal in them.

Amongst the forms of metria he would speak of one which might be termed traumatic metria, or that which was the result of operations, injuries, or lesions of any kind occurring during the delivery. We know that, during the prevalence of zymotic metria, any accidental or operative departure from the natural course of labour is likely to be attended with the most serious results; in the same way, that during the prevalence of erysipelas or phagedena in surgical hospitals, all open wounds are liable to be attacked by the prevailing epidemic. He exhibited to the Society a number of drawings of cases of traumatic metria, and reminded it of the year 1838, when so great a mortality from these cases occurred in the Dublin Lying-in Hospital. Those who have seen cases of arthritic metria would, he said, remember that the joints are most generally secondarily affected at intervals of days or even weeks after the peritonitis or metritis has run its course; but that in several of the dreadful cases of 1838 the contrary was the case, and that the knee, elbow, ankle, wrist, or sacro-iliac sychondrosis were primarily attacked. The pain in these arthritic forms was most intolerable, particularly in the case of the sacro-iliac joint; opiates failed to give relief, and caustics or the actual cautery seemed to be the most effectual remedial agents, although many of the patients sank rapidly. In those cases where hospital gangrene attacked parts injured during labour, he had seen most advantage follow the use of caustics and mineral acids, with chloride of soda lotion and antiseptic poultices. He had, at the suggestion of Abraham Colles, tried free incisions in some of these cases, but with unsatisfactory results.

The last variation of type, observed as a genus of the general family of metria, to which he would direct the attention of the Society was that which, in a paper read before the British Medical Association, he had designated "Puerperal Purpuric Fever." He had described it as an endemic that appeared in the Lying-in Hospital during the year 1837, and which in some cases showed symptoms unlike any previously seen in metria. Those symptoms corresponded in their characteristics to what Dr. Marston described in the so-called "Black Death." They were, firstly, those of profound blood poisoning; and secondly, those of cerebro-spinal irritation.

Dr. Kennedy impressed on the Society the benefit to be derived from the study of the diseases of animals, for as there was to be observed a certain similarity existing between the nervous and circulatory systems of warm blooded creatures, so their diseases seemed related, and might be advantageously subjected to comparative observation.

DUBLIN PATHOLOGICAL SOCIETY.

FEBRUARY 14.

THE preparation which Mr. Stokes brought before the notice of the society, was a specimen of

ILIO-FEMORAL ANEURISM OF ENORMOUS SIZE,

which he had recently removed from a patient in the Richmond Hospital. He was a man of about 50 years of age, a messenger in one of the commercial establishments in this city, and was obliged occasionally to carry, not only very large, but very heavy weights. The patient, according to his own account, was of temperate habits, and never had rheumatism or any constitutional disease. Abut four months ago, he observed for the first time, the sudden appearance of a tumour in the right groin which gave him no inconvenience. About two months' afterwards, however, it became so large and painful that he was obliged to seek medical advice. He was under the care of Dr. John Kirkpatrick for some time, who afterwards transferred him to the care of Mr. Stokes, in the Richmond Hospital. The diagnosis of aneurism was not attended with any difficulty. A very large pulsating tumour occupied the lower part of the abdomen in the right side, and the upper portion of the femoral region divided by Poupart's ligaments into two unusual portions, the superior being the greater of the two. A loud bruit was heard in placing the stethoscope over the tumour, and there was distinct pulsation. There were no other symptoms of organic disease, no murmur to be heard in the heart, the only thing abnormal about which was, occasional intermission. The idea of pressure as a means of cure was at first entertained, but the patient could not bear it, pressure in any situation was attended with such severe pain. The other modes of treatment as the injection of fluids with the object of producing coagulation of the blood. The introduction of the other more novel modes of treatment was out of the question. The great size of the tumour precluded all such attempts. There remained, therefore, but two courses, one was not to attempt any surgical interference, which would be to leave the man to a certain and painful death, the other was to attempt to bring about consolidation of the tumour by occluding the vessel above the seat of the aneurism. After anxious consideration, Mr. Stokes determined to have recourse to the latter procedure, and, if possible, to apply either a permanent or a temporary ligature in the common iliac artery, or if he found that to be diseased to go higher and occlude the abdominal aorta immediately above its bifurcation. The artery was exposed in the usual manner, and in getting a view of the common iliac on the right side it was found, that it would not be safe to tie it, it was not healthy, and besides there was very little of it to be seen. The aneurismal tumour overlapped three-fourths of the lower part of the vessel and not only did it conceal the vessel from view but it flattened out the artery and gave it the appearance of being very much dilated. It would have been impossible to apply the clamps then for there were extensive adhesions between the anterior wall of the artery and the peritoneal sac, so much so, that the latter was dissected off with difficulty. On making the *post-mortem* examination, under these circumstances, Mr. Stokes applied Lüer's aneurism needle round the aorta, just before its bifurcation and attached to the ligature a piece of silver wire and then applied the clamps designed by Mr. Porter for the temporary occlusion of arteries. The immediate effect of the application of the clamps was to cause a complete cessation of pulsation in the tumour. The circulation was completely arrested, not only in the vessels of the right lower extremity, but in those of the left. The patient was removed and for some hours after the operation every thing progressed favourably. Mr. Stokes remarked one serious and, to him, unaccountable symptom, that the man complained of a burning pain which he referred to the sole of the right foot and the ball of the great toe, of that side. This was only relieved by pressure, and lasted only two or three minutes at a time, returning every few hours. He got opiates, and became tranquil, and had several hours' sleep, towards midday, he took brandy and beef tea and appeared to enjoy it. In the afternoon, about 3 or 4 o'clock, he got a semi-syncopal attack from which he was roused by the exhibition of small quantities of stimulants. The pulse at the wrist became in these attacks almost unaccountable. The heart's action very weak and the lips perfectly white. As the day wore on these attacks became more frequent and more prolonged, and at the close of the day at about 8 or 9 o'clock, it became quite obvious that his end was approaching. At 12 o'clock, thirteen hours after the operation, he expired. A remarkable thing occurred in the course of this case, to which Mr. Stokes stated he had omitted to direct attention before, and that was the rapid re-establishment of the collateral circulation. Five or six hours after the operation, pulsation was distinctly perceptible in the left femoral artery.

The *post-mortem* examination disclosed the great size of the tumour which engaged the termination of the common iliac, the entire of external iliac and a portion of the femoral artery. There was no fluid blood in the tumour, which was filled chiefly with a dark mass of coagulated blood, and a considerable quantity of recently coagulated fibrin. There was extensive adhesion of all the surrounding parts to the tumour, and a portion of the pelvis was eroded.

There was no other organic disease to be found, except in the heart which was extremely fatty, indicated not only by its great friability, pale colour, and softness, but also by its microscopical appearance, which was carefully noted by Dr. Purser, who has devoted special attention to this subject. There was no peritoneal inflammation, or even congestion to be found. It is probable that this case might have had a different termination but for the diseased condition of the heart, and that death was the result of shock occurring in a person with fatty heart. Mr. Stokes looked forward to the operation of deligation of the abdominal aorta being attended with success on some future occasion. Sir Astley Cooper was most sanguine of the operation being eventually successful. He says :—"My own conviction is that it can be done, and be done with success." These remarks applied to the application of ligatures, but Mr. Stokes was of opinion that the plan he adopted on the present occasion, and which he hoped would be always adopted, afforded a much greater chance of success. One of the most common causes of want of success after ligature of the large arteries is the secondary hæmorrhage, that occurs consequent in the ulceration produced by the ligature, but, by adopting this plan of Mr. Porter's the artery can be perfectly occluded, and rapid consolidation of the contents of the tumour may be produced as this case shows, and although he had not examined the interior of the artery it was well known that the application of this instrument does not cause any injury to the internal coats of arteries. He therefore came to the conclusion that this mode of dealing with arteries in what are called surgical aneurisms is destined to play a most important *rôle* in the treatment of these affections.

◆

COLD WATER TREATMENT OF TYPHUS FEVER.

E. Brand, in a work recently published at Berlin, confirms the observations of Jürgenssen as to the efficacy of cold water applied externally, in the treatment of typhus. The propriety of a repetition of the cold water he would decide by its effects in the reduction of the temperature of the patient's skin He directs the application of the cold water to be resorted to and persisted in whenever the temperature at the armpits rises to, and continues at, 39·50° Cent. Jürgenssen directs this whenever the temperature within the anus is at 40° Cent., and to prevent a rise in the temperature subsequently to the use of the cold bath, that the patient, without being wiped dry, should be put to bed and have his breast and abdomen covered with cloths wet with cold water. By this treatment Dr. B. maintains that, in cases of abdominal typhus the occurrence of intestinal ulceration may be prevented, the only inconvenience in any case being the occurrence of a slight catarrhal affection. By this method of treating typhus only from four to six cold baths were required in the course of the twenty-four hours. Dr. B. claims for the treatment of typhus by applications of cold water to the surface, when employed from the commencement of the attack, the promptitude and efficacy of almost a specific : by it, he asserts typhus (including the exanthematic form) may be materially shortened in duration, and its mortality very much reduced.—*Centralblatt f. d. Medicinisch. Wissenschaften.*

QUINIA AS AN ANTIPHLOGISTIC.

A. Martin, in an Inaugural Dissertation, published at Giessen, in 1868, states that he has tested the conclusions drawn from their experiments, in reference to the action of quinia upon the blood by Binz and Scharrenbroich. Twelve experiments were performed by him. In two of these, repeated with every care and precaution on dogs, it was clearly shown that when the system was put under the influence of quinia, the formation or augmentation of the white corpuscles of the blood as well as the effort for their expulsion by the intervention of an inflammatory process was restrained. The experiment presented by the author to prove the curative influence of quinia upon inflammation seated in the parenchymatous viscera are new. He adduces to this intent experiments made upon frogs by laying bare the liver, in which condition, with great care, the animals may be kept alive for three days. The proper hepatic corpuscles in the frog, it is true, resemble very closely the white corpuscles of the blood, but from these they may be distinguished by their size and composition. It was shown by these experiments that the action of the quinia caused the inflammatory process to become as fully arrested in the liver as in the exposed mesentery. To test the antiphlogistic power of quinia, in four frogs the liver during fourteen days was allowed to remain exposed for twelve hours each day. Into two of these frogs, during the intervals of exposure, ·0025 grm. of quinia was injected. In the twenty preparations which accompanied the thesis of Mr. Martin, he thinks also the fact of the antiphlogistic action of quinia was fully established. It is very certain that the development of white corpuscles in the blood is far less than occurs in other cases of inflammation treated without quinia.—*Centralblatt f. d. Medicinisch. WEDNESDAY, APRIL 7, 1869.

FOOD AND DWELLINGS FOR THE PEOPLE.

Two subjects of grave importance to the community at large, and in an especial manner to that class of it unburthened and unblessed by worldly opulence, demand a far larger share of public attention than has lately been bestowed upon them. The subjects are—the peoples' food, and the peoples' dwellings.

Viewing the former as of vital importance, and the adulteration of it a crime of a very high order indeed, we are once more compelled to inquire, for what time longer is adulterated human food to be permitted for exposure and for sale by dishonest London traders? Have short measures and light weights become "acknowledged institutions" amongst us? Is avoirdupois weight to continue six drachms to the ounce and thirteen ounces to the pound? Are thieves—washed, bland, and insinuating—to retain the privilege to mix dust in our tea, add sand and lead to our sugar, chalk and plaster to our flour, rice and alum to our bread, and to ply turnips, pease, saffron, and "shot salt" *ad lib.* in the preparation of that amalgam yclept butter? In a word, are weights and measures of mercurial uncertainty, to be countenanced and to be recognised for the legitimate and standard ones of the period? And is adulteration of the peoples' food to be regarded as the very essence and life of trade? Undoubtedly the time has long since come for the application of the final screw in order to check the vicious career of the fraudulent trader. Is it to be applied? Will there be suitable machinery prepared so that it may be adopted with success, and for the advantage of the hard fisted mechanic, the toiling labouring hack, and, better still, to express even a particle of that "bitter aloes" with which the morals of trade now appear to be blended? These are grave and serious questions, questions for the present hour, questions that should be answered by the "Plot and Passion" of an outraged public opinion, with whose demand no "circumlocution office" dares to trifle.

Many, indeed, are the tricks of London traders, but one that we consider worthy the attention of our readers has lately been submitted to our notice. A purchaser, ere he left the establishment of a fraudulent trader, observed that the commodity purchased by him was in weight some ounces less than for what he had paid, and, as a consequence, demanded of the trader, in the presence of other purchasers, his full weight or his money returned to him. "I assure you its quite correct Sir, quite correct; bacon is up in the market, that's how it is; a trifle less weight, as you say, but our price is the same, just the same as formerly, for the article." The subterfuge told, for that time at all events, and the victim appeared to be satisfied with the explanation. Yet the purchaser sufficiently shrewd to question the correctness of weight or the fullness of measure he receives from the loquacious fraudulent trader, may pretend to "perfectly understand" the tenor of the words used to justify a fraud by the smooth-tongued hypocrite; but the language is generally so full, gushing, and apologetic—the thing is so well done, in fact—that he smiles, bows his head, apparently to note his appreciation of the sentiments expressed, in reality to cover a mantling blush that his stern manhood *won't* conceal; and leaves the mangling mart of slight-of-hand, of short measures or of light weights, tricked of a trifle, more or less—and he knows it!

In London at the present moment, and in the articles of human food more especially, fraudulent trading prevails to an extent scarcely to be believed. In every street, in every market, in every passage where the "staff of life" is exposed for sale, there dishonesty, in some shape or other, flourishes; and how it has happened that the conscientious traders—for there are such, be it observed—have not long since banded themselves together for characters' sake, and insisted on a thorough and a *practical* parochial or governmental supervision over articles of human consumption, appears really unaccountable.

It is simply an idle display of sound and fury, that ambulating, parochial, periodic shop and stall visiting, light weight and short measure hunting, so familiar to the ken of most of us. The parochial authorities know this; if they do not they are dolts—parochial dolts—a species of the genus not uncommon in our fortune-favoured latitude, and if the "supervisors" once in a time pounce on an "unprepared" delinquent, and haul him up before his worship, and that his worship "cautions" him firstly, and secondly fines him in the heaviest penalty the law permits, what follows? Why, this: the "delinquent" pays the fine. Is that all? O yes, there's something more. He gouges what he calls the "make-up" piece from each of his other set of light weights, clips his measure, or shortens his yard-stick (as the case may be), drives his trade at higher pressure, and "clears capital" ere the week's end, out of the indignity. In France they "post up" a dishonest trader. With us he is fined, if detected; but the crude mode employed to detect is, as we have said, an idle display—"sound and fury signifying nothing."

The application of the branding iron beneath the right malar might be adopted as a means to leave a lasting impression on the elastic conscience of a trading cheat. Would there be a possibility to form a borrow and lend arrangement between the Horse Guards and the Board of Trade? At the former there is now a "spare" branding iron; the latter wants one. Perhaps the Commander of the Forces might accommodate the President of the

Board of Trade by "lending him the loan" of —— —. "The gods don't truckle." Well, suppose they didn't heretofore; it is time they commence to do as other people do this truckling age. Lend the iron, your Highness; or, shall we apply to that man of heart, the Judge Advocate General? for, we are willing to pay full price for honest quality and full weight and measure, and wish to set a "trade mark" on the persons from whom we receive—neither.

◆

SCOTLAND.

EDINBURGH.

ROYAL MATERNITY HOSPITAL.

Last week the annual meeting of the governors and friends of this institution was held in the Council Chambers—the Lord Provost in the chair. From the report, it seemed that the income for the past year had been altogether inadequate for the requirements of the hospital, and that consequently at the end of the year the hospital stood considerably in debt. 602 patients had been provided with medical attendance during their confinement, and 236 of the most destitute of these received in addition shelter and maintenance within the hospital; and the monthly average number was about 20. From want of funds, the directors regret that many needful alterations could not be made upon the hospital. The Lord Provost regretted that such an institution should not be better supported, because it was of infinite benefit to poor people, as well as the Edinburgh school. He hoped that, wherever the new Infirmary might be placed, a portion of it would be devoted to the uses of a Maternity Hospital.

THE DEAF AND DUMB INSTITUTION.

The annual meeting of the subscribers to the Edinburgh Institution for the Education of the Deaf and Dumb was held on Tuesday, 30th ult., in the hall, George street. Sir Alexander Grant, Bart., Principal of the University, occupied the chair, and there was a large attendance of subscribers. There are at present in the institution 63 children, of whom 27 are girls and 36 boys. The pupils continue to be instructed in language as it is written, Scripture history, geography, arithmetic, writing, and drawing. In the industrial department, tailoring and shoemaking is carried on by the older boys; while the girls are instructed in household work and plain sewing. Arrangements have also been made by which exercise and amusement are afforded to the pupils. The directors acknowledged receipt of legacies to the amount of £3,164 13s. 10d., and concluded their report by exhorting the public to continue to support the institution.

LORD STANLEY AT GLASGOW.

The Rectorial address of Lord Stanley is the event of the week. It affords a great contrast to that of Mr. Froude, recently noticed. To analyse it is extremely difficult, his lordship having given full play to his powers of condensation. Still an extract or two may be culled. We hope they may induce our readers to study the address.

"We live in days of, perhaps, over-strained competition, and even those who, as far as their personal feelings are concerned, would probably be satisfied with moderate success and a tranquil career, have in most professions, hardly the choice. A rising lawyer cannot refuse briefs, a young surgeon or physician cannot decline practice. It is rarely, I fancy, in the power of any professional man to say, "Up to such a limit I will work, and no further." It may be, for my own part I think it is, a misfortune that such should be the case—that, from the tendency of mankind to run after well-known names, one competitor in a profession should have more labour cast upon him than it is physically possible that he should attend to properly, while others, hardly, if at all, less capable, are standing by unemployed. But that is a result—I suppose an inevitable result—of open competition in a fair field, and we can only accept the laws of the game as we find them. Every man, therefore, who works with his brain must be prepared, in an open profession, to find, in the event of obtaining the success which he hopes for, that his bodily as well as mental powers will be taxed to the utmost."

. . . .

"As a general rule, I think that the aim of a liberal education ought to be not to fit men for this or that special profession exclusively, but to apply such acquirements and to sharpen such faculties as shall be equally useful in any. It is not good, I am sure, for anybody to be too early and exclusively buried in his own special pursuit. If from circumstances it is necessary that he should be so, let him accept the necessity for that as for other privation without complaining. But do not let him assert or think that it is in itself a good. Law, medicine, architecture, engineering, practical art—all these are pursuits of the highest usefulness and even necessity; but no man can even dabble in them all, nor has the architect any particular use for law, nor the lawyer for architecture."

◆

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, March 30, 1869.

For the information of your readers I may mention the appointment of Milne-Edwards—who is a doctor of medicine as well as of natural sciences, and whose name is so familiar to every student of zoology—to the Directorship of the Laboratory of Comparative Anatomy and Physiology at the *Ecole Pratique*. He retains his Chair at the Museum of Natural History.

Some Englishmen, I believe, have used bromide of potassium on a large scale. If they have really studied its action with attention, and can write French, here is a chance for them. One of the Paris medical societies offers a prize of 300 francs for the best essay on the physiological and therapeutical action of this drug. True, the amount is not much, only £12 of English money, but it sounds more in francs, is as solid as a gold medal, and think of the credit of an Englishman carrying off a French prize. All essays to be sent, before the end of December next, to M. Léon Duchesne, 91 Rue de Seine, Paris.

The remarks I have made about the post-office annoyances have caused some surprise and, perhaps, vexation. I can only repeat they are true. Since they were published the same irregularities have again occurred. It is to be hoped that the exposure will lead to reformation.

On Friday, the 12th March, Professor Piorry, the illustrious consulting physician to the *Hotel Dieu*, gave one of those public lectures for which the French exhibit such a taste. It was an able discourse on the progress of practical medicine during the year. The learned doctor gave most prominence to the physical diagnosis of internal lesions. He spoke of percussion, including the use of the pleximeter, of auscultation, of the laryngoscope, the sphygmograph, the uterine speculum, and of the use to be made of measurements, and the deductions to be obtained by weighing patients from time to time.

◆

Notes on Current Topics.

Free Trade in Fraud.

There has, perhaps, never been a more extraordinary confession of faith, or one more fragrant of bureaucracy, put forward by a Minister of the Crown than that which fell from the lips of the champion of "Progressive Liberalism," Mr. Bright, in reply to Lord E. Cecil's petition or legislation against trade frauds. Great must have been the lack of argument when a senator of Mr. Bright's logical acumen was compelled to so absurd a defence of the do-nothing policy of the circumlocution office. The Government decline to protect the consumer or punish the fraudulent trader, not because the cheating is difficult of detection, nor because the evil is insignificant, nor because the remedy would be expensive. Not at all! The detection is easy, the grievance is universal and oppressive, and its suppression would be almost costless. Mr. Bright constitutes his Government the protectors of trade fraud because "adulteration arises from the great and perhaps inevitable competition in business;" and, more ludicrous still, because, "as the ignorance of customers is generally diminishing, we may hope that before long the adulteration of food may also diminish." Mr. Bright, indeed, takes the trouble to add that, not only does he side with such tradesmen, but that if they were to "be tracked by Government officers, life to them would not in this country be worth having, and he would recommend them to remove to some other, where they could carry on their business without being subject to such annoyance."

We hope Lord E. Cecil will be encouraged to repeat his question in another form, for we cannot think that Mr. Bright would have the boldness to commit himself to such puerile nonsense a second time. Surely it is exactly because adulteration must be expected to thrive in the great competition of business that ordinary remedies should be thrown aside, and the Legislature should step in to help. Surely the ignorance of customers has nothing to say to the matter, for the most highly educated have neither the time nor the means to save themselves from trade frauds. Surely it is a contemptible come-off to say that thievery is to be sheltered because some time hence people will be too smart for the thieves.

If Mr. Bright does not care to put himself in the position of Mr. Hughes or Mr. Roebuck, who lost their seats by fearless denunciation of the very acts which Mr. Bright palliates, he would at least not incur the additional penalty of being laughed at if he would frame some better excuse for his reticence.

A New and Compact Galvanic Battery.

For some time Mr. Smyly, of the Meath Hospital, Dublin, has been using electrolysis for the obliteration of nævi moles and small granules with very satisfactory results. The battery employed was that recommended by Dr. Althaus, and consists of sixteen cells in a large case, packed with sawdust in order to make it portable. The great difficulty of carrying so large and heavy a box about induced Mr. Smyly to apply to Mr. Yeates, of Grafton street, Dublin, to make him a battery more suitable for medical purposes. He has produced the most satisfactory results. The box containing the cells is five and a half inches long, two and a half inches high, and two and a quarter inches broad. It contains twenty-one cells, the couples being fused, chloride of silver and zinc, and the fluid is salt and water, which is prevented spilling by sponges which are loosely packed between the metals. Mr. Smyly has tested it with a galvanometer, and it is considerably stronger than the battery recommended by Dr. Althaus, which is eighteen and a half inches long, twelve and a half inches broad, and seven inches high. It contains all the elements for successful electrolysis. The current is strong, and can be diminished at will. The twenty-one cells being in sets of seven, the positive can be connected with either seven, fourteen, or twenty-one. The negative pole is at the opposite end of the box, so that there can be no mistake as to which is connected with the needle.

The operation is very simple. The positive pole is connected with an ordinary sponge electrode, while the negative is armed with a gilt needle or needles; the needle is introduced under the skin, and the electrode with the sponge wet is applied in the neighbourhood, taking care to move it about, as it is likely to blister the skin. Hydrogen, &c., are evolved at the negative pole, and the striatum are destroyed in contact with the needle without any appreciable loss of skin. We are promised a number of cases, which we hope in a short time to publish.

Acorns as Food.

A writer in the *Philadelphia Medical Reporter* gives some interesting particulars of the preparation of this article as food. He says:—

"The Indians collect the acorns when fully ripe, and store them in cribs, which are made in circular form, the framework being simply the pliable branches of trees fastened securely at the top. While wandering about, they carry as many acorns with them as they can, and when the supply is exhausted, the squaws make long journeys, sometimes several days' travel, to these magazines, which are generally placed at the most accessible points, to procure fresh supplies.

"Their manner of grinding the acorns and preparing the flour therefrom, so as to render it edible, is as follows: They select a large flat rock, containing on its surface holes, either naturally or artificially made. These holes are usually about six inches deep, from six to eight inches wide at the top, narrowing gradually to the bottom. The acorns, divested of the shell, are placed in them and pounded fine by heavy stones of a conical shape by the Indian women, which, with their rude appliances, is hard and slow work. The fine flour is then separated by scooping out the flour with one hand, and dashing it against a grass mat held in the other; the fine flour adheres to the mat, and is brushed off into a basket, while the coarse rolls off into the hole, to be again pounded. When the flour is ready, a large basin is made on the ground, like a mortar bed, about three or four feet in diameter, a little narrower at the bottom, and the sides are eighteen inches in height. The inside is then made smooth by the hands. This basin is filled with water heated to boiling by putting into it hot stones, heated almost to redness over a fire near by.

"The acorn flour is then added and stirred for several hours, and then left to settle. The water is then drawn off, and the flour, of a jelly-like consistence, is found adhering to the sides and bottom of this earthen basin, and is carefully scraped off by the hand. It is now sweet, nutritious, and palatable, the bitter principle of the acorn having been driven off by the heat. It may be eaten in this state, or rolled out in small loaves, and baked into bread.

"Upon this food these poor Indians rely almost entirely for their subsistence during the greater portion of the year, necessity having taught them how to make it palatable; and thus they are enabled to live where the *white* man, with similar resources, would be very apt to consider starvation inevitable."

The Brighton Hospital for Sick Children.

It is but right to direct particular attention to this institution. Its supporters are inaugurating a movement for getting rid of some of the abuses that prevail at other charities, and they deserve encouragement. We may instance one or two points that strike us in the rules and prospectus.

First of all, they require the signature of two respectable householders, certifying that the applicant for relief is a deserving object. The reason for such a rule is obvious; and, in a town like Brighton, not so difficult to carry out as it might be in London.

Secondly, the offices are to be held for a term instead of for life.

Thirdly, no proxy voting is allowed.

Fourthly, the degrading process of canvassing is prohibited.

Fifthly, no two gentlemen in partnership can be on the acting staff at the same time.

It seems to us that such rules as these have been devised with a singleness of purpose that ought not to be forgotten.

Medical Society of London.

The ninety-sixth anniversary oration was delivered by Sir D. Gibb. We regret not having been able at present to issue our usual abstract. That regret is, however, considerably diminished by the fact that the orator has published it in the form of a pamphlet, entitled "Discoveries in Science by the Medical Philosopher."

He traces with evident pleasure the part played by the long roll of distinguished Fellows of the Society, and the impetus their labours have given to the cause of science. A noble theme this, and though often told before—at least, in fragments—well worth telling again as a whole.

Sir Patrick Dun's Hospital, Dublin.

The memorial from the Physicians and Surgeons of Clinical Hospitals in Dublin to the Provost, Vice-Provost, and Senior Fellows of the University of Dublin, which, last week, we announced to be in preparation, was, we understand, presented on Saturday last to the Board. It is as follows :

To the Provost, Vice-Provost, and Senior Fellows of Trinity College.

We, the undersigned Physicians and Surgeons of Clinical Hospitals in Dublin, considering that while every guarantee should exist for the full and sufficient clinical instruction of students in medicine and surgery yet being of opinion that any unnecessary restriction on the free choice of students as to where they may obtain that instruction is inadvisable, request the earnest attention of the Board to the regulation of the University, which requires that nine months' clinical instruction shall be obtained at Sir Patrick Dun's Hospital.

We find that the attendance of students on any individual hospital is not required by the regulations of any other University in the United Kingdom; and inasmuch as we have no reason to believe that the other hospitals now recognised by the University are less capable of affording clinical instruction than Sir Patrick Dun's, we feel that the obligation to attend that Hospital in preference to others is an injustice alike to students and to the medical officers of similar institutions.

We consider that inasmuch as the obligation to attend all lectures in the School of Physic has long since been removed, and certificates are now received from all recognised medical schools, it is contrary to the spirit of the regulations as they now exist and unjust to candidates for the degrees of the University that a restriction of a portion of the requisite clinical instruction to any one hospital should remain unaltered.

We therefore respectfully submit that your Board would consult the best interests of the University, of the Hospital itself, and of medical education, by altering the regulation so as to remove the restriction which necessarily tends to hinder students seeking their qualifications in your University, and in obtaining the full advantage of clinical instruction in other hospitals.

The signatures attached to this memorial represented a thoroughly unanimous expression of concurrence in its prayer by the Hospital Medical Officers of Dublin. Of the sixty-seven Medical Officers of Dublin Hospitals, exclusive of Consulting Physicians and Surgeons, and not directly connected with Sir Patrick Dun's itself, fifty-eight or about six out of seven signed the memorial, and several of those whose names do not appear on it have expressed their approval of its prayer, although prevented by official position or other causes from recording their concurrence in its object.

We most heartily join in the suggestions which it conveys to the authorities of the University, and we are entirely convinced that neither Sir Patrick Dun's nor the School of Physic does itself justice in maintaining a protective restriction which is behind the age, and cannot fail in the long run to be prejudicial to their efficiency.

The Vacant Examinership of the Royal College of Surgeons in Ireland.

The election of an Examiner in the room of the late Mr. Collis has been, in consequence of the near approach of the quarterly examinations, fixed at the earliest possible period, the 10th of April. Mr. Collis occupied a Surgical Chair in the Court, and, unless some change shall take place before the election, the new Examiner will also take Surgery for his subject.

Amongst other names, that of Mr. Philip Crampton Smyly, Surgeon to the Meath Hospital, and son of the late Mr. Smyly, himself a long-remembered member of the Court, is authoritatively mentioned as a candidate for the Chair. The selection is made by seven members of Council chosen by lot in the presence of the assembled College, and sworn in the following very stringent form :

"I,   do solemnly and sincerely promise and declare, that I will to the best of my knowledge, skill, and judgment, without hatred, evil-will, partiality, affection, favour, or fear, justly, equally, and faithfully discharge the trust now reposed in me to elect the most fit and proper person to fill the situation of Examiner or Professor of

And further, that I consider myself bound to elect the candidate who affords the most unquestionable proofs of good character and of ability, acquirements, industy, and perseverance applied to the branch for which I am now called upon to elect a Professor or Examiner; and that I do not consider previous services in the College, in this or any other department as establishing a peculiar claim to a preference. And also, that I have not, directly or indirectly, promised to vote for, or favour, any particular candidate."

Small-Pox in Melbourne.

Considerable alarm had been occasioned at last advices by the occurrence of some cases of small-pox in this city. On the 22nd of November there arrived here the ship *Avonvale* from Foo-chow-foo. Among the crew who came ashore was the chief officer, William Webster, who had become ill on the 20th. On the 27th the case was reported to the chief medical officer's department as one of small-pox. Active and rigorous measures were at once taken. The rest of the crew proved healthy in quarantine; they were vaccinated, and in the cases in which the vaccination proved unsuccessful, the operation was performed over again. Similar steps were taken in respect of the people with whom Mr. Webster lived before he was carried to the Melbourne Hospital, and also those who were in attendance on him subsequently, including the medical attendants.

On making inquiry it was found that two of the crew of the *Avonvale* had died during the voyage, and that the disease broke out shortly after the vessel left her port of departure.

A searching inquiry will be necessary to ascertain where the blame lies, in that the *Avonvale* was allowed to pass the health officer at the Heads, and thus to place in risk the inhabitants of Melbourne. Up to this period small-pox has been virtually an unknown disease in this colony, thanks to the precautions taken to exclude it.

The Irish Poor-Law Medical Superannuation Bill.

The second reading of this measure is fixed for the 7th of April, and should it come before the House on that night, it may be expected to pass through its most important stage. As, however, the House does not sit on that evening beyond six o'clock, we can hardly expect that much progress will be made. We are strong in the hope that before the end of the session it may achieve the dignity of an Act. The views of the profession have been forcibly pressed upon the legislature both by the Irish Medical Association and the Poor Law Medical Officers Association of England, and its justice has received recognition by many Boards of Guardians throughout Ireland.

The Council of the Royal College of Surgeons in Ireland, in anticipation of the second reading, has petitioned in favour of the bill, and the Fellows of the King and Queen's College of Physicians have followed their example. At their last meeting the Council of the College of Surgeons appointed a deputation to proceed to London in company with Dr. Quinan, the secretary of the Irish Medical Association, to represent the views of the profession in Ireland to individual members, and should the measure come under discussion, we have every hope that these combined influences may carry it out to a favourable issue.

The late Mr. Maurice Collis.

The obsequies of this much-regretted member of the profession took place on Wednesday last, and the occasion evoked a most marked and unanimous expression of regret and sympathy on the part of his professional brethren. The peculiarly melancholy circumstances under which his death took place enhanced the general desire to pay a last respect to him, and the funeral was accordingly the greatest concourse of the profession which has taken place in Dublin within some years. The Fellows of the Royal College of Surgeons were invited by the Council to attend, and every rank of the profession was largely represented.

The late Mr. J. H. James.

The name of James, of Exeter, has been prominent as a surgeon for a long time. He became a Member of the London College of Surgeons in 1811, and entered the army, in the service of which he took part during the memorable period that closed at Waterloo. In 1816 he left the army, was elected on the staff of the Devon and Exeter Hospital, and began a career of success that has only just ended. Mr. James was a contributor of great importance to medical literature. Of his works, that on inflammation should perhaps be named as his most laboured one; but his minor productions alone would suffice to show that in him a great master has passed from among us.

It is said that Mr. Trevelyan is preparing a Bill intended to remodel the Greenwich Hospital funds.

The Pharmacy Act (1868) Amendment Bill is before the House of Commons as we are at press, a report of which we hope to give in our next.

Fifty aged persons of each sex—the number representing the years of the Queen's age—received the Queen's Maundy Thursday charities. The ceremony was performed in the Chapel Royal, Whitehall, by the Bishop of Oxford, as Lord High Almoner, assisted by Dr. Jelf.

At the annual meeting of the governors of the Royal Albert Orphan Asylum, it was stated in the report that Her Majesty had consented to become the patron of the institution, and the Duke of Edinburgh its president. A growing interest seems to be felt towards its objects, and the funds appear to be in a satisfactory condition.

Mr. Hall, Professor of Mathematics at King's College, has given intimation of his resignation of that chair in July next. It is intended to present him with a testimonial of the kindly feeling and respect of his friends when he leaves. Lord Stanley, Dr. Barry, Professor Goodacre, and other distinguished men have contributed.

By the efforts of the Sailors' Home Society, aided especially by its chairman, Admiral Sir William Hall, K.C.B., a home was opened at Rotherhithe, close by the banks of the river, where sailors may be lodged and fed when on shore. Such an institution was urgently wanted where the men on landing are exposed to imposition and temptation, injurious alike to their comfort and character. There is accommodation for thirty men, and a convalescent room, where men who are sick, and left behind by their ships, may be properly attended to.

Dr. Torry, we are informed, is about leaving Lincoln, and the influential inhabitants of the city intend presenting him with a testimonial on that occasion as a mark of the esteem in which he is held, and an acknowledgment of his gratuitous services in connection with the County Hospital and Dispensary. A working man requests that a subscription may be opened for the humbler classes, who appreciate Dr. Torry's services, and equally regret his removal from amongst them.

THE memorial stone of a new suburban village was laid on the 30th ult. by Lord Shaftesbury, at Loughborough Park, Brixton. The plan originated by the Suburban Village and General Dwellings Company (Limited) is intended to supply good and cheap dwellings for the working classes, to enable anyone to purchase his house at once, or by payments in the form of rent spread over seven, fourteen, or twenty years. This is, undoubtedly, a most desirable object, considering the wants of this class occasioned by the destruction of house property in the metropolis.

AT the Queen's Levee, held by Prince Arthur on Saturday last, the names of but four members of the profession were left at the office of the Lord Chamberlain for presentation. Had her Majesty held the Levee in person, doubtless the numbers of all grades of society seeking the honour would have increased ten-fold. It does, however, seem somewhat ludicrous that "presentations to H.R.H. Prince Arthur (a boy of eighteen years of age) are by the Queen's pleasure equivalent to presentations to her Majesty." This opinion appears to be best shown by the absence from Court—when the duties for the Sovereign are relegated, as on Saturday—of most personages of distinction both in and out of the profession of medicine.

WE copy from *L'International* the following details of the life of Sir Joseph Oliffe, the esteemed Physician to the English Embassy at Paris, whose death we recently announced. His career commenced in the humblest station, for when he arrived in Paris he was obliged to run of messages to earn his living. Afterwards he engaged with ardour in the study of medicine, and in 1840 passed a brilliant examination at the Faculty. He might have experienced a long struggle still, if an event had not occurred to change the current of his life. A young and beautiful Englishwoman, daughter of Alderman Cubitt, the millionaire, walking one day on the Boulevards, made a false step and dislocated her ancle. Dr. Oliffe was passing and offered his assistance, and some days afterwards the young lady declared to her father her affection for her youthful attendant. After prolonged resistance on the part of her parents, the lady carried her point, and the marriage took place. All was changed with the young doctor. Clients flocked to him, he was appointed Physician to the English Embassy, and soon afterwards received the dignity of knighthood.

◆

Literature.

PARASITIC SKIN DISEASES.*

IT cannot be charged upon the English School that skin diseases have been of late years neglected, if either the number or the value of the books issued on this subject be considered; or if the attempts to pursue the study in special institutions or to systematize it in general hospitals be taken into account. There is no department that has more completely vindicated its claim to be considered as a speciality, so that both in these islands and throughout Europe special hospitals for skin diseases exist and dermatologists are amongst the most prominent scientific specialists. We need not say that in Scotland, Dr. M'Call Anderson stands prominently forward amongst scientific physicians. He has taken up the specialty, and he has proved in his own person that Scotland may *vie* with England, France, and Germany. He has for years pursued this specialty with interest, patience and tact. His position as a lecturer on the practice of medicine and his experience at the Glasgow Dispensary for Skin Diseases have been turned to account to promote dermatology, and while we are glad to see so safe a teacher instructing a large number of future practitioners, we also rejoice that his published works enable those in practice to make themselves acquainted with his views. Unfortunately, we fear, that dermatology does not excite the interest of the masses of the profession, so much as we should like to see it do. There are too many who still grope in the dark in their skin practice, when they might enjoy full light. Too many who suffer such cases to pass away from them to specialists, when they might obtain great credit by rapid cures, too many who fall into constant errors for want of the most elementary instruction. We are speaking out plainly, and shall not be misunderstood. It is not desirable that such a state of things should exist, but we fear it is too true, and the explanation is not difficult. We have had no such teaching as is to be seen on the continent. Our special hospitals have been called into existence to meet the necessity of the diseased, but they have not been utilised for clinical instruction. We are not denying that attempts have been made. We are maintaining only that up to the present time no adequate clinical teaching of this important branch of practice has been carried out. The consequence of this neglect is, that too many of the present race of medical men have had no opportunity of learning cutaneous medicine before being launched on the responsibilities of practice. The advocates of specialism have here a strong argument, though it must be confessed that all its force is destroyed by the fact that their opponents may fairly charge them with having neglected to establish a clinical worthy of their speciality. Hospitals have been carried on, but those attached to them have not supplied the tuition wanted, and the general hospitals in undertaking to do so are only doing at great pains what the special institutions might long ago have accomplished. We should be glad to see London secure a reputation for its clinical dermatological instruction worthy of that it holds on other subjects.

If any excuse be required for these reflections, it is to be found in the exquisite defence of the specialty with which Dr. Anderson's agreeably written volume opens. He shows how specialism exists as a necessity, and illustrates how each person who hates specialism excepts one or more, till like the hog in the fable, all is devoured by good Mussulmen, who all are shocked at some portion of the animal. The story is *apropos* and we command it to those who so fiercely fight over the specialties that may, and those that may not, be recognised. But we must pass to the book before us. It is a second edition of a work that has received not only our approbation, but that of the whole profession. Dr. Anderson's reputation is now made, he writes with authority, and it is pleasant to see he is conscious of the responsibility, and that while doing justice to all he states with clearness and precision the views upon which he acts in practice. The book is devoted exclusively to Parasitic Diseases. These are divided into two classes. 1. Diseases due to the presence of a *vegetable* parasite. 2. Those due to an *animal* parasite. The first division is divided again into four, according to the parasite present. These are those mostly recognized by the writers, who have of late years laid so much stress on vegetable parasites as the cause of cutaneous diseases. It will be seen, therefore, that Dr. Anderson does not take his stand against the extension of the parasite theory, about which so much has been said, and which has been called into question so strongly in the *Journal of Cutaneous Medicine*. He accepts the recent views without reservation, and gives, as it seems to us, an unexceptionable account of the diseases from this point of view. We have no intention whatever, of entering into the controversy. Those already embroiled in it can take care of themselves. If we pass then to the second portion of the book, that devoted to animal parasites, we have to note that Dr. Anderson, unlike many writers, has finished this work with the same care. We have often been vexed at seeing this part of the subject either scamped or made a mere lengthy trash. We have read Dr. Anderson's chapters with interest. Like all he writes they are terse and well knit. He does not dish up all the anecdotes of his predecessors; nor does he disgust us with the pedantry that strings together long words and rings the changes on latin names. He sketches the habits of the *acarus scabia* in a few brief paragraphs that will not fail to impress the reader, and describes the course and treatment of scabies as distinctly and as instructively. In this last respect we may take the opportunity to remark on the too constantly followed routine in this disease. Is it not time that sulphur ointment was deposed from the place it has so long occupied as the one cure for itch? This is perhaps but an illustration of the neglect of the study on which we have commented, and one of importance too. In hospital and dispensary practice, sulphur will long hold its ground, but there must be with private cases, numerous instances when the practitioner is glad to do without that drug. It can scarcely be too frequently repeated that we may cure scabies easily enough and more pleasantly without sulphur. That agent will accomplish the *cito*. In most instances it will include the *tuto*. But in only a few can it comprise the *jucunde*. Why should we be satisfied with two out of three indications of the old writers, when all may be as easily carried out?

---

* On the Parasitic Affections of the Skin, By Dr. M'CALL ANDERSON. Second Edition. London: J. Churchill, and Sons.

Dr. Anderson's book is a sound, safe guide to practitioner and student. It is written as we have said, in a clear and terse style, in which the meaning is never obscured. We should add that the author's excellencies are enshrined in the best possible setting. Type, paper, printing, engravings are all of the best, and the edges are considerately cut; so that the volume may remain on the shelf without the injury that accrues from ragged edges, and is one of the handsomest that Messrs. Churchill have this year issued. It is but right we should add that the author thanks his friend Dr. John Wilson, for executing a number of accurate drawings from which the illustrations have been taken. These, both wood-cuts and lithographs, are all that can be desired, are no less than 33 in number, and we may add are embellishments worthy of the text.

Correspondence.

SUGGESTED INFANTICIDE AND ABORTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In discussions on Malthusian doctrines and "remedies" for "over-population," it ought to be distinctly understood on all sides, that the medical profession absolutely refuses to have any hand in, or to countenance, any kind of infanticide, abortion, or means for rendering intercourse unfruitful (excepting, of course, those cases in which craniotomy or artificial abortion, may be necessaay to save the mother's life, proceedings which should always be sanctioned by a second opinion). I do not find that any such distinct understanding has been put forth; nothing has been said; and people have been left to form their own conclusions. Our opinion ought to be clearly expressed; it is time to speak out on this subject; and he is not true to his profession, but is a very unworthy member of it, who does not firmly refuse to countenance any such acts as those alluded to. Let this, the only sound and honest position, be openly taken up, and then, with this basis, no one need fear being misunderstood in whatever part he thinks proper to take in discussions upon this question. What conclusion may be come to, if any ever is, matters much less than that the character of the medical profession should stand firm and pure.

I am, Sir, your obedient servant,

W. E. C. NOURSE, F.R.C.S.

Brighton, April 2nd, 1889.

MONSIEUR PERREVE ON FORCIBLE DILATATION OF STRICTURE OF THE URETHRA.

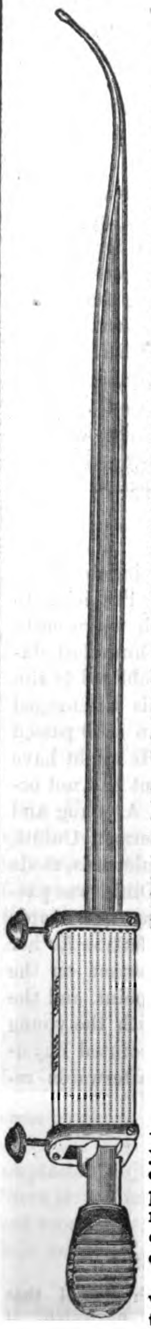
TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having been anxious to ascertain the experience of my friend, Monsieur Perrève, upon the dilator treatment of stricture of the urethra since the publication of his "Traité des Rétrécissements Organiques de L'Urètre," in 1847, I communicated with him upon the subject, and received the courteous and important reply which I now append.

It will be perceived, from his letter, that he still follows the mode of using the dilator, described in his treatise, and has been so eminently successful as not to have lost a single patient.

M. Perrève, you may remember, did not, with scarcely an exception, complete the dilatation at one *séance*, in any of the one hundred and fifty to two hundred cases, either fully, or partially, reported in his book. To this practice some would probably attribute his great success.

I have recently followed the method of not fully dilating the stricture by a single use of the forcer* at *one séance*, in the case of a man beyond middle age. The result has been most satisfactory. At the first operation I dilated the stricture with my double-bladed dovetailed dilator (Fig.) and one forcer, equal to No 11 of Weiss' catheter gauge. After the expiration of a few days a larger forcer was used, equal to No. 14½ of the same gauge.



The double-bladed dove-tailed Dilator.†

The first of these sizes (No. 11) produces enlargement to an extent to which, I am well aware, M. Perrève would not probably dilate at a first *séance*; nevertheless, according to my experience, I considered it might be permitted with safety. The employment of the second size (No. 14½) was produced by a moderately rapid action of the forcer, and with scarcely any pain.

The method usually adopted by M. Perrève, of not producing the full amount of dilatation upon the same day, appears to me to be well worthy of an impartial trial. Unfortunately, however, the sympathetic connection between the constitution and the urethra is so capricious (the most careful use of ordinary bougies and catheters occasionally leading to severe, if not fatal, results), that it is difficult to draw perfectly safe conclusions regarding some of the mechanical modes of treating stricture of that canal. One point is peculiarly worthy of reflection with respect to the treatment by means of dilators, namely, that although this mode of dealing with stricture has now been prominently before the profession for several years, and, like many other surgical procedures, has had, and, indeed, continues to have, its detractors, pathology has not yet *unmistakeably* solved the following question:—What is the probable state of the urethra in the majority of persons whose strictures have been submitted to this treatment? Such a *necroscopic silence* appears to me to be a powerful argument in favour of mechanical dilators.

Apprehensive lest I may be misunderstood, let me, in conclusion, remark that whether we complete the enlargement either *at one*, or in *two or more séances*, my observation has convinced me that, in dealing with the urethræ of these countries, the action of the dilator must be most extensive and complete, particularly in bad cases, or it will be of little service.

Your obedient servant,

March, 1869. B. WILLS RICHARDSON.

M. Perrève's Letter.

Paris, Feb. 9, 1869.

"MONSIEUR AND VERY HONORED CONFRERE,—In your kind letter of the 28th of January, you ask me for some observations upon cases of stricture taken, during my practice, since the publication of my "Traité sur les Rétrécissements de L'Urétre," in 1847; and you have obligingly added that you would record these observations in a medical journal.

"Had I foreseen such a friendly request, I would have taken notes of the patients I have treated; but, since my work was published, I have thought that cases were no longer required, and I have altogether ceased to take them.

---

* The wedge which divaricates the two blades of the dilator.

† For a description of M. Perrève's instrument, see the numbers of this Journal for December January, and February, 1866 and 1867.

"Therefore, it is only from memory that I must consign to you notes of a few patients whose treatment presented difficulties; and I shall commence with:—

"1. Monsieur Goirin, by birth a Spaniard. This patient had entered the Hospital Beaujon, which he left after five or six days, without the surgeon having been able to pass the stricture with the finest bougies.

"Immediately on leaving the hospital he sought me; but, as after several weeks he had been in a state of almost unspeakable suffering, I treated him at his own house.

"The first *séance* was prolonged and difficult; nevertheless, without departing from the rules of prudence, I was able, on this occasion, to dilate the urethra two lines in diameter, which allowed the patient to micturate freely. The rest of the treatment, which was completed in three more *séances*, presented absolutely nothing abnormal.

"2. Monsieur Génin wrote to me from his bed, that, being confined by a complete retention, he begged I would repair to his house. (It was the physician of his family who persuaded him to take this step.)

"Three years previously, on the occasion of an attack of complete retention, a false passage had been made at the seat of the stricture; much blood escaped without in any manner changing the position of the patient. This circumstance, joined to the pains M. Génin experienced, rendered my first *séance* useless; the patient, however, micturated a little. The second *séance* was, I believe, also without result. It was otherwise with the third, for, on this occasion, I succeeded in clearing the stricture, and in carrying the dilatation to more than two lines in diameter.

"The remainder of the treatment did not present anything unusual. I think I performed four or five *séances*.

"3. Monsieur X. (a Spaniard, whose name I must forbear to mention). This patient was treated, for more than a month, by one of the most celebrated surgeons of Spain, and as the treatment by this honorable *confrère*, in place of diminishing the disease, seemed, on the contrary, to increase it, he recommended him to come to Paris and submit himself to my treatment. The patient came. The treatment presented great difficulties; yet, after the expiration of three weeks, I had carried the dilatation to three lines, or three lines and a half in diameter.

"I could give the cases of many other patients whose treatment presented difficulties more or less; but to what purpose, since, with a little time and much prudence, I have always triumphed over these difficulties?

"Before bringing my letter to a close, I must observe that we should never employ force against the obstacle, and that we should cease all dilatation as soon as we experience the sensation of a resistance overcome while we are pushing the wedge between the blades of the instrument. It is from having religiously observed these two precepts that I have never had the pain of losing a patient.

"Receive, my dear *confrère*, the renewed assurance of my friendship and of my obligations.

"Vr. Perreve,
"No. 69 Rue St. Honoré.

"Monsieur le Docteur Richardson."

THE APOTHECARIES' HALL OF IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Inasmuch as it was I that announced in the *Pharmaceutical Journal* that "the Company have given their consent to a Bill, having for its object the qualification of a class of Pharmaceutical Chemists in Ireland," I may be excused trespassing on your valuable space for a few words in reply to Mr. M. D. Crofton's letter, which appears in your impression of this date.

I think your correspondent has taken a very one-sided view of the case altogether. The leading article which he so unmercifully condemns must have produced a very peculiar impression on his mind. The remarks therein contained are perfectly consistent, provided that the Pharmaceutical Society of Great Britain can extend its influence to this country after the contemplated "Bill" has become law; and even should not such a beneficial change in the practice of Irish Pharmacy be effected—which is extremely improbable—you are only endorsing the opinion of such learned medical gentlemen as Sir Dominic Corrigan, Dr. Aquila Smith, and Dr. Acland, whose views on the subject are well known.

I perfectly agree with Mr. Crofton as regards the superior knowledge of practitioners who have served an apprenticeship to an Apothecary over those who deem three months' hospital dispensing quite sufficient for all future responsibility. I learn that the present state of medical education does not necessarily compel a qualified medical man to be able to know jalap from rhubarb, and if this be true a few years' manipulation with the pestle and mortar, under the guidance of an experienced pharmacist, is absolutely necessary to fit a physician or surgeon for the safe practice of his arduous profession. By the way, the words that I made use of in the *Pharmaceutical Journal* are not mine, but Dr. Leet's; and of course he is in a position to explain any ambiguity they convey.

I beg to state, for Mr. Crofton's information, that my sole object in writing this letter is to hasten the day when monopoly shall be swept away from the field of Pharmacy. Hoping you will give this letter an early insertion, I beg to subscribe myself

Your faithful servant,
T. J. Monaghan.

March 31, 1869.

Summary of Science.

[The Editor of this Summary wishes it to be understood that he not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

(*Specially Edited and Compiled for the Medical Press and Circular.*)

By C. R. C. Tichborne, F.C.S., Mem. Coun. R.G.S.I., &c.

Drs. Carpenter and Wyville Thomson's Report on Deep Sea Dredging.

The survey-ship "Lightning," having been assigned to the above service, was supplied with the most approved sounding apparatus and thermometers. Dr. Carpenter has forwarded a Preliminary Report to the Royal Society, which contains some important observations. As stated in Professor Thomson's original letter to Dr. Carpenter, the objects of the investigation were as follows:—

All recent observations tend to negative Professor Forbes' opinion, that a zero of animal life was to be reached at a depth of a few hundred fathoms. Animal forms had been proved to be abundant at a depth of 300 fathoms. Many of these are new to science. These forms differ greatly from those met with in ordinary dredging; and in some cases they seem closely allied to, and would seem to be directly descended from, the faunæ of the tertiaries.

One of the questions to be solved, is the effects of pressure upon animal life at great depths. "Probably," said Professor Thomson, "a perfectly equal pressure to any amount would have little or no effect. Air being highly compressible, and water compressible only to a very slight degree, it is probable that, under a pressure of 200 atmospheres, water may be even more aërated, and in that respect more capable of supporting life, than at the surface."

These points have been in a great measure determined by the late expedition:—

It was found that a pressure of 100 atmospheres is not incompatible with animal life of numerous and varied forms.

The distribution of the animal life of the seas beyond the Littoral zone is more closely related to the temperatures of the water than to its depth.

This brings us to a very curious part of the Report—Dr. Carpenter's remarks upon the minimum temperature; which he says is as low as 30° (0°6) over a considerable area. They say there is no physical improbability in the existence of a stratum of sea-water at a temperature of 30°, or even 28° underlying a stratum at 39°, for sea-water, in virtue of its saline impregnation, contracts continuously down to its ordinary freezing point, which is below 28° Faht. M. Despretz says that the results of experiment prove that the maximum density of sea-water, cooled down continuously, without agitation, is 25·4 Faht.; when agitated, 27·4. "The cold waters doubtless come down from the North to replace the warm waters sent through the Gulf Stream to moderate the cold of Spitzbergen." Says Lieut. Maury, in recording the temperature of the Gulf Stream, "Its surface temperature was 80°." The deep-sea thermometer of the Coast Survey has recorded a temperature as low as 35°. The actinic rays seem to penetrate the sea-water to a great depth, for bright colours were not wanting—orange, red.

Astropecten, and small annelides from 650 fathoms were distinguished by the vividness of their red and green colourations.

Further Remarks on Occluded Hydrogen.

Graham has assumed that hydrogen may be viewed as a hypothetical metal, which he has called "hydrogenium," and that palladium, with its occluded hydrogen, is merely an alloy of that metal. The density of palladium, when charged with hydrogen, could not be determined by the ordinary manner, because when immersed in water a continuous evolution of minute hydrogen bubbles are determined by contact with the liquid. However, the linear dimensions of the charged palladium wire are altered so considerably, that the difference admits of easy measurement, and furnishes the required density by calculation.

Supposing that the two metals (hydrogenium and palladium) united without any change of volume; the alloy would be a compound of—

Palladium	100	or 95·32
Hydrogenium . . .	4·908	or 4·68
	104·908	100·

The expansion of the palladium, from 100 to 104·9, appears enormous, if viewed as a change of bulk in the metal, due to any physical force, amounting, as it does, to eighteen times the dilatation of palladium when heated from 0° to 100 C. The density of the charged wire is reduced by calculation from 12·3 to 11·79. Again, as 100 is to 4·91, so the volume of the palladium 0·1358 C.C. is to the volume of the hydrogenium, 0·006714 C.C. Finally, dividing the weight of the hydrogenium, 0·01147 grms., by its volume in the alloy, 0·006714 C.C., we find density of hydrogenium 1·708. The density of hydrogenium then appears to approach that of magnesium 1·743 by this first experiment. On the further expulsion of the hydrogen from the wire, the latter contracts, and is after the experiment almost as much shorter as it was previously lengthened. The wire is permanently shortened; but the contraction is in length only. This is, however, partially due to the effects of wire-drawing in leaving the particles of the metal in a state of unequal tension. This tension is excessive in the direction of the length of the wire. The metallic particles seems to become mobile, and to right themselves as the hydrogen escapes. A wire so charged with hydrogen, if rubbed with a powder of magnesia, to make the flame luminous, burns like a wax thread when ignited in the flame of a lamp.

When the occluded hydrogen is expelled by heat the metal loses much of its power to take up hydrogen.

The tenacity of palladium-wire being 100, the tenacity of the palladium and hydrogen is 81·29. The tenacity of palladium is therefore reduced, but not to any great extent.

The addition of hydrogen adds manifestly to the small natural magnetism of the palladium. It appears, therefore, that the hypothetical metal hydrogenium is magnetic. This magnetism is not perceptible in hydrogen gas, which was placed, both by Faraday and Becquerel, at the bottom of the list of dia-magnetic substances. Hydrogen, associated with palladium, unites with chlorine and iodine in the dark, reduces a persalt of iron to the state of protosalt, converts red prussiate of potash into yellow prussiate, and has considerable deoxidizing powers. It appears to be the active form of hydrogen, as ozone is of oxygen.

On the Method of Assaying Silver Compounds in the Wet Way.

M. Stas proposes to substitute bromides for chlorides in estimating silver solutions, by Gay Lussac's process. This modification is introduced for the purpose of remedying the solubility of the chloride of silver in the solution in which it is formed. The solution of the silver salt is not obtained by using a bromide.

Test for Nitrates and Chlorates.

Dr. Brawn puts into a porcelain capsule 1 C.C. pure concentrated sulphuric acid, and then, drop by drop, ½ C.C. solution of sulphate of aniline; the whole is then slowly stirred with a glass rod, the stuff to be tested having been previously added.

The presence of a very minute quantity of nitrate will produce zones of a beautiful red colour, caused by the formation of fuchsine. A chlorate will produce a splendid blue colour; nitrates produce a red colouration.

Sugar and Dextrine in Glycerine.

The following test is given:—Five drops of the glycerine to be tested is added to 100 or 120 drops of water, three to four centigrammes of molybdate of ammonium, one drop of pure nitric acid (25 per cent.); the whole boiled for about a minute and a half. If any sugar and dextrine are present, the mixture assumes a deep blue colour.

Hydrofluoric Acid.

Mr. G. Gore describes the anhydrous acid in a paper read at the Royal Society. It was obtained by heating dry double fluoride of hydrogen and potassium to redness in a platinum apparatus. The lutings were of paraffin, sulphur, and lampblack. Nearly all the operations were effected while the vessels containing it were immersed in a freezing mixture.

The anhydrous acid is a most dangerous substance, and requires great care in its manipulation. It is colourless and transparent at 60° Faht., very thin and mobile, extremely volatile, and densely fuming in the air; it absorbs water very greedily from the air. It is perfectly retained in platinum bottles, the bottle having a clamp-screw mouth and paraffin washer.

The molecular volume was determined. One volume of hydrogen in uniting with fluorine produces not simply one volume of gaseous product, as it does when united with oxygen, but two volumes, as in the case of its union with chlorine. The specific gravity was ·9879 at 55° Faht. The anhydrous acid is much more volatile than ether; its boiling point was found to be 67° Faht. Not the slightest sign of freezing occurred on cooling the acid to 30° Faht. On loosening the lid of a bottle of this acid at 60° Faht., it is expelled in a jet-like steam, as from a boiler. The acid had scarcely any effect upon any of the metalloids, or noble metals, and even the base metals, in a state of powder, did not cause any evolution of hydrogen. Sodium and potassium behave in the same manner.

The Relation of Chemistry to Physiology.

MM. Pelissard and A. Cahours have presented a memoir to the Academy on the physiological action of conia and its compounds. Ethylconia, and iodide of ethylconia, are like conia in this respect: that they lead to poisoning of the pneumogastric nerves, differing, at the same time, in possessing a less energetic and more passing action on the voluntary nerves. In *equal conditions* conia is more poisonous than ethylconia; and is again even less poisonous than the iodide of ethylconia. The introduction of the radical ethyl with conia abolishes the period of convulsions which precedes the paralysis. This is particularly seen in poisoning by iodide of diethylconia. The animal falls incapable of making any voluntary movement.

Adulteration of Opium.

Mr. J. King, in the *American Journal of Pharmacy*, notes the adulteration of this important and expensive drug. Samples were examined containing 14 per cent. of starch. The starch granules differed from any of the common starches, being larger than those of wheat and corn, and smaller than those from the potato; it approached more nearly the starch from the bean, both in size and form.

Dichloro-Acetic Acid as a Cauterizer.

This acid has been prepared by Dr. F. Urner for this purpose. It does not produce a strong inflammation upon the surrounding parts, and is accompanied by less pain than other cauterizers—stronger as well as weaker ones.

◆

Gleanings in Medicine, Surgery, and the Allied Sciences.

A NEW METHOD OF ARRESTING HÆMORRHAGE.

On the 21st of November, 1868, Dr. Frank H. Hamilton removed a schirrous breast, when he adopted the following method for controlling hæmorrhage during the operation: Dr. Hamilton says (*New York Medical Gazette*) in order to restrain the bleeding until the vessel could be secured by ligatures, I adopted the following procedure which I have never used before nor seen suggested by others: After the patient was fully under the influence of ether, I encircled the chest with two long strips of adhesive plaster, each of which was about two inches in width and long enough to surround the chest completely and allow the ends to overlap each other. They were drawn tight, but not so tight as to interfere with respiration. One of them passed under the breast at a point about one inch from the line I had indicated to myself as the probable line of incision; the other passed above the breast, between it and the axilla, at about the same distance from the projected upper line of incision; the two strips of plaister forming an ellipse completely enclosing the breast. Within this ellipse the incisions were made, and it was apparent that by the pressure of the plaisters the bleeding from all the tegumentary and superficial muscular vessels was completely, or almost completely controlled; so that the amount of blood lost in the operation was comparatively trifling. On closing the wound I did not remove these strips. This was an error which on another occasion I should avoid, since they prevented the complete and accurate coaptation of the tegumentary flaps and allowed the margins of the wound to become everted.

SPONTANEOUS POPLITEAL ANEURISM OCCURRING IN A DIABETIC SUBJECT; FAILURE OF MECHANICAL COMPRESSION; CURED BY FORCED FLEXION.

M. **Verneuil** communicated a case of this to the Academy of Medicine of Paris, the interest of which consists in the coincidence of the diabetes, and in the fact of compression, which is usually so efficacious and so innocent, having failed and even produced local lesions of some importance. M. Verneuil terminated his narration with these propositions. 1. The coincidence of spontaneous aneurisms with diabetes, although it has not before been remarked upon, demands serious attention, as it exerts great influence in the choice of the procedure, and raises new questions on the etiology of aneurisms, and the composition and properties of the blood in diabetic subjects. 2. It almost absolutely contra indicates the employment of the ligature, and renders the application of compression very difficult, in consequence of the ease with which eschars are formed under the pads of the apparatus. 3. In spite of the presence of glucose, the blood appears to preserve its plastic properties, or, in other words, its aptitude to deposit fibrinous layers in the sac or active coagula. 4. The anti-diabetic regimen, so different from that ordinarily prescribed during the mechanical treatment of aneurism, does not destroy this aptitude. It would seem, then, prudent to institute such treatment when the general condition calls for it, and to persist in it even after the real or apparent disappearance of the glucose. 5. In popliteal aneurism, the forced flexion of the leg on the thigh is a very important procedure calling for renewed trials. It is harmless, of easy application, and little onerous, inasmuch as it requires neither costly apparatus nor numerous assistants. It demands on the part of the patient a little intelligence and perseverance, and on that of the surgeon a surveillance easy of execution. 6. In some cases it has been attended with very rapid success in the hands of the English surgeons; but in those in which its first trials prove fruitless, it may eventually succeed by employing short *séances* at long intervals. 7. Its efficacy doubtless depends upon certain conditions, which have as yet been little studied, such as the position and dimensions of the vascular fissure, the relations, dimensions, and consistency of the sac, &c. In the present case it has probably operated as indirect compression. 8. The prolonged, unnatural direction imparted to the knee-joint has given rise to no serious inconvenience, the articular stiffness gradually disappearing and the limb recovering all the amplitude of its movements. 9. The cure, it must be admitted, required a very long time; but then it must be recollected that without flexion it might have been altogether impossible, and most certainly would have been more painful and dangerous. 10. It is true that attitude has been aided by other accessory means, such as direct and indirect compression, but it is to it that recovery is chiefly due. It confirms the conclusion that, in difficult surgical cases, the practitioner, far from obstinately confining himself to a single means, should assemble, combine, and concentrate all the resources which science has placed in his hands.

THE IMPORTANCE OF CERTAINTY IN THE OPERATION OF VESICO-VAGINAL FISTULA, AND THE BEST MEANS OF SECURING THE GREATEST SUCCESS.

Dr. Bozeman, in a communication to the Medical Society of the State of New York after stating that the maximum of success was 92 per cent. of all cases consecutively presented treatment, endeavoured to show from statistics the real difference in the results that had been secured with the usual forms of suture now in general use, including the double rows of interrupted silver suture and the button suture. He said, although the above limit of success had not heretofore been quite reached with his button suture, still he believed it would be with the valuable aid afforded by his late improvement, consisting of a self-retaining speculum and a supporting and confining apparatus. This he said did away with the necessity of assistants, and enabled him now to operate successfully upon a small class of cases previously unmanageable, The most obvious results from those improvements, however, he thought would be seen in the diminution of the number of operations actually required, and of the consequent suffering of the patient. In support of his statements, he then narrated five cases presenting seven fistulous openings, one a vesico uterine, all of which had been cured at six operations, since the adoption of the two improvements above made. The size of the fistula and the peculiar adaptation of his suture required in each of these cases, he illustrated with models made of buckskin and the same buttons that had been used, After summing up the results of these operations he called attention to the great value of the *linen list* which he had used a number of years as a means of diagnosis in cases presenting fistules so small as to escape the closest search with the probe, especially those opening into the cervical canal known as *vesico-uterine*. He also called attention to cases of fistule complicated with laceration of the anterior lip of the cervix uteri, and showed the importance of the procedure first adopted by him in their management. His classification of fistules, which is an extension of that of Velpeau, he still thinks is preferable to any other that has been proposed, it being considered more in harmony with the anatomical peculiarities of the parts involved and the modifications required in his suture apparatus to suit individual cases.

ATROPHY OF THE HEART.

The following general results are presented by Dr. N. **Finn**, of the Pathologico-Anatom. Institute of St. Petersburg, as having been derived from the examination of one hundred hearts. 1. Simple atrophy is never developed as the only morbid condition. It is unattended by a morbid condition of the cardiac blood vessels. 2. Neither the absolute or relative weight of the heart, thickness of its walls, nor their reduced circumference can be received as a certain indication of the presence of atrophy of the organ. 3. The brown atrophy of the heart, so-called from a morbid change in the colouring matter of the muscular tissue, is a common accompaniment of all diseases attended with great emaciation. 4. Fatty degeneration of the heart (fatty infiltration) occurs chiefly in persons who have a large development of the subcutaneous adipose tissue; the infiltration is often to such an extent as to prove troublesome. 5. Fatty degeneration of the heart occurs as an acute or a chronic affection. It is observed more frequently on the right than on the left side of the organ. In some cases the entire substance of the walls of the ventricle are affected, in others only a portion. In the chronic form there is always atheromatous degeneration of the cardiac blood vessels. The *arcus senilis* is never met with in cases of fatty degeneration of the heart.—*Centralblatt f. d. Medicinisch. Wissenschaften.*

MODERN HOMŒOPATHY.

From the *London Monthly Homœopathic Review* for June, 1868, we learn that Lord Ebury gave vent to a feeling of regret that the report of the London Homœopathic Hospital did not contain evidence of a greater development of the objects of the institution. The number of patients was not very large, and the clinical lectures had been given up, "owing to the attendance being so scanty as greatly to discourage the lecturers." In the London Homœopathic Hospital, in which the cases are not of so serious a character as one is accustomed to see under treatment in hospital, black wash is applied to syphilitic sores, and ½-grain doses of mercury given internally. Cases of glandular enlargement in the neck were treated with tincture of iodine painted on externally. For cases of continued sleeplessness 1·48 of a grain of acetate of morphia was given every fifteen minutes. The Hospital physicians repudiated, one and all, the fallacies and absurdities of Hahnemann about infinitesimal doses and dilutions. They frequently told inquiring physicians that "the doses were not a part of *their* system; that like cures like was all *their* creed; although it is not a matter of general or partial belief that morphia keeps people awake, that iodine produces enlargement of the gland, and black wash produces syphilis. These Hospital physicians, and many others, have at last returned to the use of the medicines of the rational school in appreciable quantities; and the editor says the treatment in the above cases "was far too like allopathy to be advisable in a homœopathic hospital," although "so long as the doses of mercury did not produce mercurialism, our opponents cannot (or rather should not) complain." He also said he would avoid painting a glandular enlargement in the neck with tincture of iodine publicly in a homœopathic hospital, although he might unhesitatingly do it in private practice. And formally admits:—"As regards the giving of morphia for sleeplessness, however necessary it may be considered by the medical attendants, it cannot be called homœopathic treatment." The homœopathic editor trusts his readers will thoroughly understand that he has no wish to object to those methods of treatment *per se*, although unsuitable for a hospital called homœopathic. We are hardly surprised to find that Dr. Yeldam, physician to the Homœopathic Hospital, in what is called an excellent speech, delivered at the annual meeting of the Institution, referred to the possible expediency of a middle school which would embrace both homœopathy and allopathy; and Dr. Reith said he knew many homœopathists who are prepared for the coalition. The editor of the *Homœopathic Review* "has not the slightest doubt that some such step, (or surrender) would be fraught with incalculable advantage to practical medicine," and it remains for us to see in what it should consist. If Hahnemann was so utterly mistaken about the efficacy of his infinitesimal doses; if every observation which he made upon the sick was an error; if every supposed cure was simply a recovery, it is not only not possible, but probable, that much of his reasoning and theorising about the *similia similibus curantur* is also false? If the frank and practical homœopathists must make such large concessions about the dose, will they not also be soon obliged to make equally large concessions about the theory? If we can judge from the following prescriptions, some of the homœopathists can make every required concession: Quin. sulph., gr. viij; ext. cannabis ind., gr. iv; ext. aconit. *rad.* gr. iv. Make 8 pills; 1 every three or 4 hours. F——r. Hydrarg. sub. mur., gr. iij; mass hydrarg., gr. iij; aloes, gr. iij; podophyllin gr. ⅛. Make 4 pills; to be taken at once. F. Magnesia sulphat., 3 oz.; tinct. cort. aurant., 16 oz.; acid. sulph. aromat., ½ oz. M.

KRISTELLER'S METHOD.

Herr Hilderbrandt referred (*Berliner Klin Wochenschirift*) to this method of expressing the fœtus, at a meeting of the Königsberg Med. Society, April 14th, 1868. He first resorted to it with great hesitation, and in a case favourable for the trial it succeeded so well as to astonish him. It was in the case of a second pain, in transverse position, head on left ilium, four extremities presenting. An assistant had failed in an attempt to turn by the feet. H. put back both feet, then the arms, caused the head to present, by means of pressure from without then made one or two strong compressures *a la* Kristeller, and saw, during the same, the rapid and happy birth of a living child. Since then he has tried the method in a number of cases, and recommends it.

EARLY TREATMENT OF THE INSANE.

In the province of Westphalia the directors of the Marsberg and Lengerich Insane Asylums have ordered that native patients shall be subsisted free of cost during the first year of their malady. This is done in order that cases may be placed under treatment while yet in the initial stage. They claim to cure 80—90 per cent. of all cases admitted during the first month of the disease, fewer with every additional month, and. assert that incurability is the rule ofter one year's duration. —*Berliner Klinische Wochenschrift.*

INTESTINAL PUNCTURE IN TYMPANITES.

Under the advice of Dr. Foussagrives, intestinal puncture, as a last resource, has been several times practised at Toulouse, on two patients suffering with tympanites. In the first case, the abdomen formed an immense mass; the patient was perfectly cyanosed and suffocating. An exploring trocar was inserted into the most distended part of the lower umbilical region. The gas escaped so violently as to extinguish a candle. The distension returning next day, two fresh puncture were made in different places, and gave so much relief that the life of the patient was prolonged four days. In another case six punctures were successively made until the gases were naturally evacuated, and the patient cured.—*L'Un. Med.*

WEIGHT OF THE BRAIN.

At a meeting of the Vienna Society for Psychiatria and Forensic Psychology. Prosector Dr. Meynert gave some statistics on the weight of the brain. His deductions from the weight of 351 brains, as well as those of Parchappe from 284, prove that the influence of psychoses is much greater than age on the weight of this organ. For example, during the physiologically blooming age of the brain's weight (30—40 years in males), a mean of only 1,317 grammes was given, because brains of the later stages of psychoses were mingled with the others weighed; on the other hand, in the primary stage of psychoses, without regard to age, a mean of 1,329 grammes was given for conditions of depression and 1,359 for mania. Furthermore, the reduction of weight was always equal to the duration of the disease. It was also found to depend upon the intensity of the latter, as paralytic idiocy was characterized by a great reduction of weight. Meynert also found that insane brains had more cerebellum, proportionally, than sane; and that insane females had more that insane males.

PERTUSSIS.

Oppolzer says (*Wiener Med. Presse*) narcotics and astringents appear to reduce the duration of the disease about one-half. Belladonna is probably the best, but simply because of its narcotic action. Tannin acts well in the third stage, or that of expectoration. In the case of children one or two years old, he began with pulv. rad. belladonna, gr. 1-12th morning and night, gradually increasing up to gr. 1-8th, or gr. 1-6th, taking the pupil as a guide. Emetics are only given when the bronchial tubes are filled with masses of mucus. To those who were arrived at years of discretion, he also gave soda bicarb. ʒss., in a tumbler of sweetened water, a mouthful to be swallowed just before an anticipated paroxysm, for diluting the phlegm. The following also acts well the same part:—

℞ Coccionella, gr. v.—viij.
Potassæ carbonatis, gr. x.
Aquæ f. dest., f. ℥j. M.

Sig. Give a tablespoonful every two hours.

Change of air is good, even if patient can be removed but a few miles. If this is not procurable, keep the patient in a room with an equable temperature. For the resulting anæmia use good diet. Dr. Link's extract of meat is good. Medicine may also be required.

In conclusion, it may be stated that of late many French physicians recommend the exhalations from lime which has been used in purifying burning gas, or, better still, gaséol. Oppolzer has had no experience with these remedies.

Medical News.

Poor-law Medical Relief.—From a return just issued it appears that the sum expended out of the poor rates for medical relief in England and Wales during the year 1868 was £272,341. The amount expended for vaccination in the same period was £50,987 against £41,256 in 1857. Poor-law medical officers received as remuneration for their services in 1868 £253,620; being an increase over the sum paid in 1857 of £39,964.

According to the latest reliable reports, the bodies of 33 men and boys engaged at the Highbrooks Colliery, Wigan, at which the fearful explosion of fire-damp occurred on Thursday last, have been recovered from the pit, and the necessary order given by the coroner for their interment. There are unfortunately several others so seriously burned, that little hope is entertained of their recovery.

Cod Fish skin, heretofore considered quite worthless, and given away to any one who would take the trouble to haul it, is now, after having been ground fine, to be used as a fertiliser. This new kind of guano is said to be free from the disagreeable odour of the ordinary fish manure.

Convalescent Home for Women and Children.—The Oxford University Amateur Musical Society have announced a concert for this evening at Willis's Rooms, in aid of the funds of the St. Mary Magdalene Convalescent Home for Women and Children leaving Queen Charlotte's Hospital.

Historical; 1100.—At Biddenden, in Kent, were born Elizabeth and Mary Chulkhurst, joined together by the hips and shoulders, and who lived in that state thirty-four years, at the expiration of which time one of them died; the survivor was advised to be separated from the corpse, but she absolutely refused, saying, "As we came together so we will also go together," and about six hours after her sister's decease she was taken ill and died also.—*A B C Advertiser.*

Lecture.

ON FIBROUS TUMOURS OF THE UTERUS.

By James Palfrey, M.D.,

Assistant Obstetric Physician to the London Hospital; formerly Obstetric Physician to the Farringdon Lying-in Charity, and to the Metropolitan Free Hospital, and to the Surrey Dispensary, &c., &c.

Lecture I.

Gentlemen,—I am sure that all those of you who have been associated with me in the examination of, and the prescribing for, the obstetric out-patients at this hospital must have been impressed with the frequency with which cases of fibrous tumour of the uterus, or, as they are more popularly called, "uterine fibroids," come before us. Now, this very frequency, combined with the facility in diagnosis which many of you, to my knowledge, have acquired, has led me to fear that you might (while having in yourselves confidence in diagnosing these conditions) come to overlook many very important matters relating to the pathology, progress, prognosis, and treatment of these growths. For I must remind you that, however important it is that you should be adepts in diagnosis, your duty to your patient does not cease when your opinion of her condition has been formed. In after life it will neither be satisfactory to yourselves that you are able completely to "make out" your case, nor beneficial to your patient if, having done so, fears and doubts as to the ultimate issue of the condition you are dealing with arise, or uncertainty as to the proper step to take at any period of the progress of your case harass and distress your mind, destroying the partial satisfaction you felt at your readiness in diagnosis, and leaving the patient but little the wiser and by no means the better for the visit you have paid her. This thought, I say, has induced me to ask you to follow me in the present, and probably in a subsequent, lecture while I endeavour to put before you very simply as much as we at present know concerning the nature, progress, and treatment of these fibrous tumours of the womb; and at starting let me assure you that it is not my intention to weary you with unnecessary details or statistics. Should it be the desire of any of you, however, to become minutely acquainted with the latter, I can refer you to the various authors on gynecology who have enriched the literature of our profession. Of our own countrymen I need only mention the names of Simpson, Lee, Ashwell, Clarke, Lever, Rigby, West, Hewitt, Churchill, Routh, and others. Ever of Continental obstetricians the name of Scanzoni will hold a very high position and command more than esteem. Should you then be unsatiated, I need but to mention the names of Meigs, Bedford, Sims, Hodges, and Emmet, of America, to insure for you a rich feast of figures bearing upon the subject before us. Notwithstanding my desire to avoid troubling you with unprofitable details and figures, yet, in the course of my remarks, it probably will happen that I may make some observations that may appear dull and uninteresting—if so, I ask you to bear with me, more especially as it must have been patent to all of you that the few minutes we are able to devote to each separate case, as it presents itself in the out-patients' room, suffices only to convey to your minds the *main* features of each individual example of uterine disease; *there* I am only able to guide you to the most important points of each case in relation to its diagnosis and therapeutics; *here* I shall ask you to join me in investigating the causes which have been at work in producing the physical conditions that have presented themselves, the symptoms we have observed, and the treatment we have adopted in the several instances that have from time to time occupied our attention.

One word more, gentlemen, will bring to a close the preliminary remarks I have thought it judicious to make to you before entering on the very interesting topics which will engage our minds. You will, I am confident, agree with me that is essential, in order rightly to appreciate the diseased conditions to which any organ of our body is obnoxious, that we should first make ourselves acquainted—nay, more, most thoroughly conversant—with the structure and functions of that organ while in a healthy state. Need I then ask, if you desire with success to study the diseases of the female sexual organs, first to master completely the anatomy and physiology of the pelvis and its contents; and if any of you should have in any degree neglected this important preliminary, I commend to your careful study that splendid article on the uterus and its appendages, written by Dr. Arthur Farre, in the "Cyclopædia of Anatomy and Physiology." You will find it in the fifth volume, at page 545, *et seq.* I can only for myself assure you that, although I have many times perused this monograph, on each successive occasion I have concluded its study with increased pleasure and profit.

Having now completed this brief introduction, let us at once pass to the consideration of these fibrous tumours of the uterus which have, by different authors, been also named "fibroids," "fibro-muscular tumours," hard fleshy tubercle of the uterus; muscular tumours (Dr. Wilks); and it will be well at the outset that I define exactly what I mean by a growth of this kind.

By a fibrous tumour of the uterus I understand "a growth" which is developed in some portion of the muscular wall of the uterus; "in consistence" it is dense and hard; "in size" it varies from a small hazel-nut to that of the pregnant uterus at term, or even larger; "its shape" is dependent mainly on its position in the uterine wall in which it is developed; it is invariably, at its circumference, surrounded by a layer of cellular tissue less dense than itself, and which, in the majority of instances, is easily detached from the denser portion which is beneath it. With this definition before you, let us for a few minutes consider the pathology of these growths. These fibrous tumours are developed in the wall of the womb itself; they are composed of the same tissue as that wall, that is to say, they are made up of fibres of cellular and some fibrous tissue—in fact, a fibrous body of the uterus is generally an excessive development of that portion of the muscular wall of the organ in which it is found. Hence has arisen the suggestion that these growths should be named "muscular tumours of the uterus," although, for my own part, I shall always prefer the term "fibrous," seeing that in the majority of instances in which I have examined these growths in the cadaver I have found them to consist of a tissue more resembling fibrous than true muscular substance. Generally the growth is diffused in texture, and presents to the eye an irregular "mammilated" surface. As a rule, I believe, you will find that these tumours are developed singly within the uterus, although the instances are not very rare in which I have seen several springing from the walls of the same organ; and one obstetrician has recorded a case in which as many as sixteen fibrous bodies were found after death protruding into the cavity of the uterus, and some of these were of considerable size. The nutrition of these growths appears to have a close relation to their density, for the harder masses are bloodless, and their injection is impossible; while in the softer varieties vessels of considerable size that are capable of injection are found penetrating the growth itself, as well as supplying branches to the layers of fibrous material which connect the lobules of the growth. And now, concerning the position in which these fibrous tumours are developed, I am able to put you in possession of some interesting and important facts. Although it is perfectly true that you may find them in any part of the tissue of the uterine wall, yet, practically, we find that some portion of the uterus is but little obnoxious to their formation; for instance, all authors are agreed that the development of one of these growths in the cervix uteri is a circumstance of great rarity, and my own experience most fully coincides with this statement—in fact, I have never seen a case in which that portion of the uterus can be said to have been the starting point of a fibrous body. Again, we find that in the majority of cases these growths occupy the superior position, and fundus of the uterus. Somewhat rarely they are found in the anterior wall, and my own observation has led me to the opinion that by far the larger number of cases in which these tumours appear singly, they will be found to occupy the posterior wall of the organ near the fundus, and at the bedside, gentlemen, this question of position is of great importance, as we shall presently see. Obstetricians have generally agreed to deduce from the accidental position in which fibrous tumours are found a classification of these growths, which conveys to our minds at once a correct idea, not only of the position in the uterine wall in which the neoplasm is situated; but also to a considerable degree, the impression to what extent such a growth is amenable to any form of treatment. Let me then describe to you the various positions in the uterine wall, from which these fibroids take their origin, and they are three in number—1st. The sub-peritoneal; 2nd. The interstitial; and 3rd. The sub-mucous. I will briefly describe these three varieties, and of the 1st, or "sub-peritoneal fibroid". In this form of growth or growths, we find one or more tumours generally of a round or ovoid shape, which springs out of that part of the uterine substance that is immediately beneath the peritoneal covering of the organ, and they possess a base of considerable breadth. As their name implies they are always invested by the peritoneal covering of the uterus, which, in the course of their development is carried forward with the growth, so that after a lapse of time, in conjunction with the base already mentioned a pedicle is formed, which in each instance varies in length, and at times is so long as to allow the tumour to hang more or less freely in the cavity of the abdomen or the pelvis, as the case may be. As a rule, these sub-peritoneal growths are remarkable for their intense hardness and their low vitality, they are seldom the cause of death in women who become the subjects of them. Finally, in connection with the first variety, I may mention that the pedicle of these growths becomes sometimes more and more fragile, until at length by accident being broken, the growth is found completely at liberty in the abdominal cavity, and can be moved hither and thither, at pleasure; such an example of this rare condition some of you have recently had an opportunity of witnessing among the out-patients, in a case which was sent to me by Dr. Alexander Fox, who sought my opinion concerning the patient. These growths generally attain a large size, and I have often seen them when they have weighed some pounds. The second variety, as its name implies, the "interstitial fibroid," is a growth contained wholly within the uterine wall, neither encroaching on the uterine cavity on the one hand, nor protruding externally on the other; as a rule, these growths do not attain to the large size which we find in the sub-peritoneal form just considered; there exists with these tumours a distinct boundary, formed by cellular tissue of a loose character, with which the growth is so lightly connected, that it may, without much difficulty, be detached and turned out of its investing capsule when the uterine wall, which covers it is incised, and their vascular relations to the uterus are not intimate. Now you will readily understand that very early in their progress growths of this sort interfere with the normal shape of the cavity of the womb, and if the tumour should attain to a considerable size, the whole organ rises out of the pelvis. Dr. Graily Hewitt has drawn attention to an interesting fact that now and then these interstitial growths are so shaped that their escape from the pelvic cavity is prevented; and then the functions of neighbouring organs are interfered with, and alarming symptoms present themselves. I can myself fully verify the truth of this observation of Dr. Hewitt's, for I have, on more than one occasion, seen an instance in which an interstitial fibroid developed in the posterior wall of the uterus of very moderate size; but prevented from its irregular form from rising out of the pelvis has produced by its pressure on the rectum such insuperable constipation, that the patient has succumbed to the symptoms which, as you know, are attendant on the complete obstruction of the large intestine at its lower portion. The third variety which is again named from the position in which it is developed, is termed the "sub-mucous fibroid;" in every respect it resembles the form I have just described to you; but, growing in the uterine wall immediately beneath the uterine cavity, it projects into that space and in exact proportion to its size it distends and enlarges the area of the cavity itself, as you will readily understand. Occasionally, beneath the mucus membrane covering the growths is found a thin layer of uterine tissue in a normal state. It is impossible for these sub-mucous growths to enlarge without a corresponding lengthening of the uterine cavity, and that portion of the tumour which impinges into the cavity usually being of a cresentic form, presses upon the opposite wall of the uterus, stretching and expanding it. The position of these sub-mucous growths is various; like the interstitial fibroids, they are "encapsuled," and, should the progress of their developement be sufficiently rapid they become pedunculated, when they form the growth called fibrous polypi, of which we shall have more to say hereafter; and now I will finish all I have to say to you upon the pathology of fibroids, by making one or two remarks upon the alterations which take place in the uterus, in any portion of the walls of which a growth of this character is located. As soon as a fibrous body which has been developed in the uterus acquires a certain size, for example, the size of a walnut; the parenchyma of the uterus, as also the mucous membrane, which lines the cavity undergo positive changes, which, with a little practice, you will readily recognize; although I must tell you that in the cases of sub-peritoneal growths these changes are not so well marked, nor so frequently observed: in fact, I have seen these growths of large size attached to the fundus of a womb which has become shrunken and atrophied; when, however, the growth is of the second variety, true hypertrophy of the whole of the muscular wall of the uterus results, the blood-vessels are actually enlarged, and the mucous membrane becomes congested and tumefied. As in pregnancy, so with these tumours, for after they have increased beyond a certain size they project, not only into the cavity, but also into the neck of the womb, and in the course of their developement the inferior segment of the body and then the cervix is encroached upon, so that the neck gets shorter and shorter and thinner until the os uteri often presents an appearance similar to that observed when about to open at the commencement of labour. With these changes, of course the cavity of the womb, as a whole, is lengthened. You have seen I am sure, instances in which we have been able with ease to pass the larger portion of the uterine sound into the uterus. And of this lengthening I shall have more to say when speaking of the diagnoisis of fibroids. Again, before I recal to your minds how often I have pointed out the fact, that a growth situated in the wall of the womb soon by its weight induces a displacement of the organ, and as a rule, the version resulting inclines towards that part of the pelvic cavity which corresponds to the seat of the tumour; thus, a fibroid of *moderate* size in the posterior wall causes a retroversion, and this condition remains until the pelvic wall opposes a barrier to the increase of the fibroid, in which case the development continuing, the growth is supported by the pelvic wall, and then the fundus uteri is pressed against the anterior boundary of the pelvis, so that you will not be astonished to find in those instances in which a retroversion has been observed early in a case, that this condition has been changed to one of anteversion some considerable time subsequently. Again, assuming the fibroid still progresses in size, the pelvis at length becomes too small to contain it, then it ascends, and slowly takes its position in the abdominal cavity; of course, dragging the uterus with it, and hence, when fibrous growths have attained a large size, we have difficulty in reaching the os tincæ when making a vaginal exploration. Not only are these changes of the uterus itself observed, but alterations in the position of the bladder and rectum ensue. The former viscus unable to dilate becomes first irritated, and this in turn goes on to a true catarrh; the rectum also from prolonged pressure in like manner becomes congested, and constantly we are called upon to treat one of the most painful complications of fibrous tumour, hæmorrhoids. These vesical and rectal troubles are often the cause of more pain and suffering than the neoplasm upon the presence of which they depend.

Lastly, do not forget when giving an opinion upon a case of fibroid disease, that now and then these neoplasms undergo certain changes which ultimately result in their destruction, or rather I should say, their degeneration, and in this way, the patient becomes cured of her malady. That fibroids are ever absorbed, I do not for one moment believe, but we have, in the *post-mortem* room, seen instances in which that kind of ossification known by the term, calcareous degeneration has taken place. True inflammation of a fibrous body I have never witnessed, although I have often seen active inflammation of the peritoneum covering a fibroid of large size in the wall of the uterus.

Original Communications.

ON THE MODE OF ACTION OF THE CHOLERA POISON.

By Arthur Ernest Sansom, M.D. Lond., M.R.C.P.,
Physician to the Royal Hospital for Diseases of the Chest, City Road.

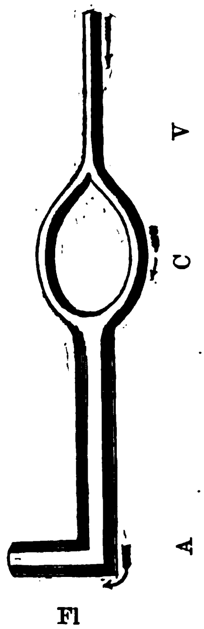
(Continued from page 265.)

Collapse and the other phenomena of cholera.—According to some observers, the lesions of the intestinal canal which I have sketched out are sufficient to account for all the phenomena of cholera. The effects are chiefly produced by the passive flow of the fluids of the organism through those portions of the intestinal tract which are denuded of epithelium. According to Pacini's views:—"The water gradually running off, the volume of the blood and its hydrostatic pressure are reduced; the impulse of the heart grows feebler, the viscidity and density augment, and the velocity of the current of blood becomes less and less; hæmatosis and calorification and the pulmonary function fall to the lowest ebb; hence the fearful collapse. The secretions dry up, ulcers dry up, and as the blood is denser, and its hydrostatic pressure is diminished, its endosmotic force is proportionally augmented; it does not nourish, it is nourished by the tissues; venous absorption increases, and the thirsty blood sucks up from every fibre and cell every drop of accessible organic water. The vocal chords sound no more; cramps shake the muscles; the glands secrete no tears, no bile, no urine. The body is dried up like a mummy; yet the brain amidst the vast disorder, shielded by the skull and sustained by the atmosphere, loses little of its organic matter, and retains its faculties for some hours, until, lulled mercifully into a semi-syncope of sensibility, it at last dies."[1] Prof. Pacini has constructed, upon a series of careful observations, a table of mathematical data, which goes farther than the closest reasoning to prove many points of his theory. It must not be forgotten, however, that errors may exist in the premises.

The first difficulty which would seem to obtain in this matter is that, according to the testimony of excellent observers (as Dr. Gull says, in his report), "the intensity of the symptoms is often, in no considerable degree, greater than can be accounted for by the intensity of the effusion." Certain cases have proved fatal with alarming rapidity in the manifestations of collapse, though there has been little or no flux from the bowels. Such cases, sometimes known as Cholera Sicca, have, however, presented on *post-mortem* examination epithelial denudation, though diarrhœal expulsion had not taken place. Pacini shields himself from these objections by showing, according to his observations, that the gravity of the case, though chiefly depending on the superficies of intestine denuded, is also increased by the velocity of the flow. The argument of those who urge that the loss of organic water is the great factor of collapse, and the nature of the correlated conditions may perhaps be better understood by the adjoined diagram, wherein A

---

[1] Report of the Cholera Epidemic of 1866 in England, p. 72.



represents the artery, C the capillary plexus, V the vein, and Fl a supposed point of exit of transuded fluid, the flux. It is obvious that, as the liquid exudes from Fl, the contents of V become more viscid ; the blood contained in C and A is diminished in quantity by the draining away; and A, being a contractile tube, diminishes in calibre. The consequence of this contracted state of A is a deficient supply of arterial pabulum to all the tissues. Many signs concur to show that this contracted state of the arteries obtains in the collapse of cholera, and the same is observed after death. This is a fact of great importance, not only as accounting for the symptoms—the shrivelled features, the thready pulse, the cold skin, &c., all consequences of an inadequate blood supply—but as eliminating a source of error. It has been argued by some that the collapse of cholera is due to paralysis of the sympathetic. The signs just mentioned are the *exact opposite* of those produced by paralysis of the sympathetic. Elsewhere I have more fully pursued this branch of the subject, and have shown that if there be any special condition of the sympathetic nervous system it must be that of irritation—of super-activity.[1]

Is Pacini's view adequate to explain all the signs and symptoms in the various cases of cholera collapse? As I have just shown, the one great cause with him of the condition known as collapse is the loss of organic matter from the body through the denuded portions of the intestine, and the consequently increasing viscosity of the systemic blood. But how does this explain those sudden cases in which, according to many observers, there is but a small quantity of flux and yet a considerable quantity of systemic blood? Why should the blood vary as to viscidity or fluidity in different cases? Why, moreover, in certain instances a restoration "almost as sudden and complete as in cases of patients who are resuscitated after suspension of animation from submersion in water?"[2]

These considerations, in my opinion, render it necessary that we should have a cause additional to the drain of fluid ; but the difficulty would be overcome if we could admit as a concurring cause an irritation of the sympathetic nervous system—an irritation which, acting upon the vaso-motor nerves, should contract the arteries, and so force the blood into the venous system. Such an irritation could occur in one of three ways, or in any combination of the three.

First, by the irritations propagated to the sympathetic ganglia by the local lesions of the intestinal canal. Such effects would have their analogies in the symptoms induced by swallowing certain corrosives—in those accompanying perforating ulcers of the intestines, in those attending severe and sudden injuries of parts highly endowed with sympathetic filaments ; witness the case of blows upon the epigastrium, or upon the testicles. In all these conditions are presented effects resembling in kind the phenomena of collapse.

Secondly, by irritations propagated to other parts of the nervous system. The phenomena are not consistent with any irritation of the encephalic centres, but the case is very different in regard to the spinal centres. Here let me pay a tribute to the good work performed by Dr. John Chapman. His elaborate exposition of the manner in which exalted function of the spinal chord and sympathetic ganglia can produce symptoms of the same nature as those occurring in cholera, is a work of great value.[1] While I agree with him that such a condition may be a concomitant (perhaps a very important concomitant) of the condition of cholera collapse, I deny that it is the prime factor. The spinal irritation is the consequence of the intestinal irritation, and is one of the correlated causes of collapse. What a powerful effect irritation of the spinal chord produces upon the systemic arteries, inducing their contraction, is demonstrated by Prof. Lister's observations in the Philosophical Transactions, 1868.

In the *third* place, irritation of the sympathetic might reasonably be supposed to occur from contamination of the blood—the circulating fluid containing a material that acts upon the nerves and ganglia which, as Prof. Beale has so ably demonstrated, clasp, surround, and are in immediate relation with the whole arterial and capillary system. I have shown that many agents absorbed into the blood are capable of this kind of action.[2] These are, to my mind, circumstances which almost incontrovertibly point to the conclusion that there is a certain blood contamination in cholera. In what other way could be explained the fact that, when a pregnant woman has died with cholera, the fœtus in utero has presented the *post-mortem* signs characteristic of cholera? Buhl anatomised twenty-two such infants, and never failed to find choleraic appearances.[3] Pacini agrees that absorption takes place from the intestinal canal in all cases of cholera of a duration of two hours and upwards ; he admits that the blood becomes contaminated from the decomposed tissues, and he thus explains the phenomena of the reactive fever. There surely is a fair *prima facie* probability that the germs existing and multiplying by myriads in the intestinal canal should be absorbed into the current of the circulating blood. There are many, however, who deny that germs when in the blood have any power of multiplication and development. On this point the evidence of analogy may be taken. Dr. Beale's conclusion, that such proliferation can occur in cattle plague, is clear and unmistakeable. He says :—

"In an animal about to be infected with cattle plague it appears probable that the minute living particles having reached the surface of the mucous membrane, perhaps already rendered suitable for their nutrition by previous morbid changes, gradually multiply amongst the soft epithelial particles until some of those produced reach the walls of the capillaries almost immediately beneath. It is possible that some of them may be drawn down the windpipe during inspiration, or even into the air-cells of the lungs. In the latter case they would gain a very ready access to the surface of the capillary wall.

"We may suppose that at the time the particles came into contact with the vascular wall, the capillaries happen to be distended, and consequently their walls so thin as to permit small particles to pass through them. Such a state would obviously favour the entrance of minute particles into the blood. One can conceive them gradually extending like particles of an amœba, and slowly insinuating themselves through the capillary wall; or they might become imbedded in the germinal matter of the capillaries, and in this way gain access to the blood. Having reached the interior of the vascular system, they would circulate with the blood, and for a time would give rise to no symptoms whatever; but in consequence of possessing highly active powers of growth, they would grow and multiply, increasing at a greater rate as their numbers increased."[1]

[3] Report of Medical Officer of Privy Council, p. 433.

It is therefore rendered very probable that disease-producing germs can and do proliferate in the blood. It is exceedingly likely that in cholera where, in the intestine, breaches of continuity are so abundant, absorption of the molecules may be easy. Intra-uterine cholera, then, might be thus explained: the germs absorbed into the maternal blood would be transmitted through both circulations; arrived in close relation with the fœtal intestine, the germs would find that nitrogenous soil (meconium) in which they have greatest power of development; here they would manifest the same morbid effects on the epithelial lining as those germs in the maternal intestine, whence they were first absorbed.

From these outlines I think we can gain a comprehensive idea of the nature and mode of operation of the poison of cholera. From all the testimony we can come to no other conclusion than that the prime factors of the disease are organised molecules, having definite phases of vital history; that these are transmitted from individual to individual chiefly by the evacuations; that, arrived in the alimentary canal under circumstances favourable to their vitality and their powers of reproduction, they become mechanical irritants of the mucous lining; the irritation being propagated to the sympathetic nervous structures, there are not only emesis and diarrhœa, but super-activity of the various glandular organs. The same irritation, however, which produces this glandular activity produces also (through the vaso-motor portion of the same nerve) activity of the unstriped muscles which regulate the calibre of the arterial channels. So here are two effects produced from the same cause, yet mutually antagonistic. If the glandular stimulation is in excess there is augmentation of secretion (*e.g.*, the increased flow of bile and urine in the early stages); if, however, the vaso-motor excitation becomes in excess, the glandular organs must perforce gradually cease to secrete, as their supply of nutrient material is cut off. The vessels of the lung participate in the general contractions in a still more marked degree, because the bulk of the tissue is made up of channels with muscular walls more capable of contraction. Not only do the branches of the pulmonary artery, by their contraction, impede the entrance of the blood into the lungs, and dam it in the cavities of the right side of the heart, but the branches of the pulmonary veins (largely endowed with contractile power), contracting *pari passu* with the channels of the arterial system, force the blood into the venous radicles. All the body suffers from arterial anæmia; the surface turns livid and shrinks (as if its arteries were contracted from another cause, intense cold), and the muscles, bereft of the natural stimulus of a proper supply of blood, suffer cramps and convulsions.

Thus, during the whole course of the malady, the cholera-genic molecules are producing their morbid effects upon the gastro-intestinal tract, upon the sympathetic nervous system, and upon the blood; and then, expelled from the body in the alvine flux, they become able in their succeeding generations to excite anew, in fresh individuals, the symptoms of the disease.

I have thus given, imperfectly in many respects, the broad outlines of a theory which I believe fully to explain the phenomena of cholera. Now, I am convinced that this theory can be made of real practical value in its suggestiveness of a right treatment of this fell disorder. It shows of what great importance are measures of disinfection—those processes whereby the septic germs are destroyed or deprived of that vitality which enables them when transmitted to the human organism to multiply and produce their morbid effects.

Furthermore, it urges upon us the study of those agents which, when absorbed into the alimentary canal of the living organism, may arrest the vitality of these germs in the midst of their disease-producing energy.

I believe that, though sulphurous acid and the sulphites possess this power in a high degree, we have in carbolic acid an agent capable of a still more energetic action in this direction. It is my hope that in the double salts of carbolic acid (the sulpho-carbolates) which I have introduced, and in the study of which I am now engaged, we have a vehicle for the administration of this powerful septicide at once convenient and safe.

◆

PATHOLOGICAL OBSERVATIONS.

By Dr. R. Beveridge,

Physician and Pathologist to the Royal Infirmary, Aberdeen.

Fractures of the scapula or of the pelvis are of comparatively rare occurrence, and perhaps the following cases, in which the state of parts was verified by *post-mortem* examination, may therefore be interesting:—

Case 1.—*Fracture of Scapula.*—D. I., a full grown, stout young man, was driving a railway van along a narrow street when the horse took fright and ran off. The wheel was passing within a few inches of the wall on one side, and the driver, in endeavouring to stop the horse, was caught between the wheel and the wall, and severely crushed. On being brought to the hospital he was found to be in a state of collapse, and the hand, on being laid on the back of the right shoulder, detected crepitation in various directions. The skin was unbroken, but the bruising and resulting ecchymosis were very considerable. Although he recovered from the collapse, yet he never thoroughly rallied, and after a time it was apparent that the tissues around the scapula were too much destroyed to recover their vitality, and were passing into a state of gangrene. He lingered about a fortnight, and gradually sank.

The following were the *post-mortem* appearances:—Skin over the back of the right shoulder dark coloured, fœtid, with several sloughy-looking openings; the dark colour extending from the neck to the lower part of the chest, and from the right side across to about the middle of the left shoulder, gradually fading away beyond these limits. Muscles connected with the right scapula dark and in a sloughy state; long muscles of the back dark coloured on their surface, the colour gradually fading in their interior, and becoming natural on their deep surface. Right scapula split into fragments thus:—Acromion and outer part of the spine completely detached from the rest, partially driven through the bone, and but slightly connected with the clavicle, the ligaments being mostly torn through; the inner half of the spine with the supra-spinous fossa detached and forming a separate fragment; a vertical fissure extending through the infra-spinous fossa, parallel to the base, the upper part of this fissure depressed (*i. e.*, driven forwards) along its outer edge, gradually resuming its level towards the lower part where a simple fissure only existed, and that not passing quite through the thick lower border of the bone; the tip of the coracoid process broken away. The muscles in front of the scapula were almost natural. Beneath the lower angle of the scapula discolouration and ecchymosis extended to the ribs, but these last were uninjured. The pleura and peritoneum were natural. No attempt at reparation.

---

[1] Report to Commissioners appointed to Inquire into the Origin, Nature, &c., of the Cattle Plague. London, 1866, p. 153.

This case illustrates well the peculiar effect produced by a crush between a moving body and one at rest. The injury is confined to the side acted on by the moving body, and while the skin by its elasticity usually escapes, the tissues beneath are extensively destroyed, and any bone near the surface is split in all directions. The same thing is seen in the effect of a spent cannon ball, and is also shown in the following case of fracture of the pelvis.

Case 2.—*Fracture of the Pelvis.*—J. S., a labourer, aged fifty-five, was returning home from market by a railway train, and on its nearing the station where he was to get out, he stept from the carriage before the train was completely stopped. In so doing he missed his footing, and fell on the foot-board of the carriage which was still in slow motion. He was caught across the pelvis between the carriage and the platform, and dragged along a short distance. On being removed he was found in a state of great collapse, and was brought into hospital, where he died in about half-an-hour, having survived the accident scarcely three hours. On laying the hand over the pelvis, the left side was found evidently to be crushed in, the crest of the ileum being moveable, and the hip very much flattened. The left lower extremity was shortened with the toes inverted, presenting the same appearance as in dislocation upwards of the femur.

The following were the *post-mortem* appearances :—Skin slightly abraded on both sides over the great trochanter, but not lacerated. On raising the skin it was found to be completely detached from the lateral muscles of the abdomen on the left side, which last were extensively torn from their attachment to the crest of the ilium. The muscles of the hip were much destroyed, and mingled in fragments with fluid blood. The left ileum was completely shattered up to the linea innominata, which remained unbroken ; the forepart of the crest, with the two anterior spines, and about the anterior half of the iliac fossa, formed one fragment ; the posterior half of the fossa was shattered into several pieces ; the upper half of the acetabulum was broken away, thus offering no obstacle to the ascent of the head of the femur, which (although the ligaments remained entire) assumed the position presented in dislocation upwards, being higher than natural, with the trochanter turned forwards and the head of the bone backwards ; and the fifth lumbar vertebra was split nearly transversely across. The femur, peritoneum, viscera, and great vessels of the abdomen escaped uninjured.

Here also the skin was scarcely injured, while the soft parts beneath were extensively lacerated, and the bone completely crushed. The lateral strength of the arch formed by the os innominatum prevented its being broken in, but the outer expanded part forming the iliac fossa gave way in all directions, while the wrenching force was so strong as to tear across the last lumbar vertebra, and—probably by pressure on the trochanter—to drive the head of the femur so strongly against the upper lip of the acetabulum, that the latter gave way. It is interesting to note that when this occurred the femur assumed the same position as in dislocation upwards, showing that it is the position of the axis, and direction of the plane of the head of the bone that tends naturally to place it thus when the mechanical obstacle of the arrangement of the joint is in any way removed. It could not in this case be muscular action, inasmuch as all the rotators inwards were torn to pieces, and their bony origins above detached and loose, while the bulk of the rotators outwards remained uninjured ; and it is probable in this natural tendency, from the lie of the bones, to rotation inwards, that we have the explanation of the necessity for the large development in man of the external rotator muscles.

Lastly, the circumstance that in both these cases the whole mischief was produced at the spot where the moving force was applied, while the opposite side of the body escaped, seems to show the rapidity with which the crushing effect was produced, before time was allowed for the force to be equalised, or any chance given for the parts giving way at their weakest points—thus producing a marked difference between the results here and those produced by a blow or a fall. In the case of fracture of the scapula, the shoulder at rest was crushed in by the moving wheel ; in that of fracture of the pelvis the body in motion (with the train) was crushed in by the edge of the platform at rest ; so that the cases are precisely the converse of each other, but both show that it is elasticity and not strength that can resist the action of force in progressive motion.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Mr. Henry Lee's Clinical Lecture.

Some late references to public enquiries render the time opportune for a note on a late clinical lecture by Mr. Henry Lee. Of this lecture we had intended to give a very full report, but as since the abstract has been at the printing office, Mr. Lee has published the lecture in the new volume of St. George's Reports, we need merely give an outline, and refer those interested to that source. Having observed that the idea of the plurality of syphilitic poisons originated in Dublin, and remarked on the effects attributed by patients to treatment, Mr. Lee passed on to the Admiralty Committee of 1864. This committee he tells us, gave particular attention to the following points :

1. Whether mercury is an agent to be indiscriminately resorted to in the treatment of syphilis.
2. The proportion and nature of the cases in which its administration is useful or necessary.
3. The proportion and nature of cases, if any, of primary and secondary disease in which it may be entirely dispensed with ; characterising the forms of disease, if any, in the treatment of which mercurial agency is not required.

The committee in their report state, that " whether a given local affection will result in syphilis cannot be known with certainty until the constitution is actually involved." The committee divide venereal ulcers into two kinds—the " simple local sore " and the " syphilitic sore." The local sore prevails over all others in the ratio of about four to one. *With the exception of this purely local sore*, all venereal sores are liable to contaminate the constitution. The syphilitic sore presents itself in three forms—one characterised by induration throughout ; one soft in its early stage, and becoming subsequently indurated ; and one soft throughout its whole course.

The evidence the committee believe is conclusive as to the impossibility of pronouncing with certainty upon its first appearance. Even though it remain soft throughout its course, it is not certain, although highly probable, that it will prove to be non-infecting. Thus, a non-indurated sore is a purely local sore if it turns out not to infect the constitution ; it is a syphilitic sore if it does. The original distinction between the two classes of sores is here entirely given up ; and no answer is given to the question of the Admiralty as to what forms of disease may not require the administration of mercury !

Mr. Lee does not find this explanation at all satisfactory, and speaks of the two following cases as typical of two forms :

Case 1.—A. L. was admitted into St. George's Hospital in June 1865. This patient underwent a series of inoculations from her original affection. She was inoculated until the matter from that series produced no further effect. The inoculations were all allowed to take their natural course, and all healed about the same time—a series, nine successful. Specific inoculations were made in this case. The patient had never had any former disease, and was subjected to no constitutional treatment. She was seen nearly two years afterwards, and had up to that time been suffering from no constitutional disease.

CASE 2.—J. M. was admitted into St. George's Hospital on the 11th July, 1865. This patient had a large circular indurated sore on the internal prepuce. This at first was not purulent, but it was made to suppurate artificially. The sore had not begun to heal. The secretion from it was inoculated again and again until no more secretion could be obtained, and yet without any result. No local inoculation could be performed in this case, for the reason, I doubt not, that the patient's whole system was already infected.

In the early stage of this case the glands in the groin had become inoculated; the result of that inoculation was not the production of pus, but the same kind of circumscribed induration or adhesive inflammation which occurred at the original seat of the disease.

Mr. Lee believes that the two forms of local syphilitic action, of which these cases are examples, are distinct and separate actions, and do not, in their uncomplicated state, give rise to each other.

His conclusion from this affects the doctrine of syphilization, for neither this nor any method of treatment affecting the constitution could be appropriate to a mere local disease.

SURGICAL SOCIETY OF IRELAND.

MARCH 18, 1869.

DISEASES OF THE JAW.

MR. CROLY read the following cases:—

CASE 1.—*Secondary cancerous tumour involving the entire submaxillary gland and the lower part of the jaw from symphysis to angle; removal of the gland with the affected portion of the bone, leaving the teeth and alveolar process.*

T. D., aged fifty-three years, residing in the Queen's County, was admitted, under my care, into the surgical wards of the City of Dublin Hospital, on the 7th of October, 1868.

History.—He was operated upon for epithelioma of the *left* side of his lower lip in September, 1867, by the usual V-shaped incision, and as there was a small gland under the jaw, corresponding to the submaxillary region, I removed it. There was a very small gland at the *right* side also, which was difficult to feel, as it slipped up behind the jaw and projected into the mouth, requiring a peculiar manipulation to dislodge it. The patient said that this small kernel was there for a long time. I cautioned him, if it enlarged, to come up to hospital and have it removed, but he neglected doing so for twelve months. On his return to Dublin, in October last, the *left* side was perfectly natural; a tumour was observed on the right side the size of an orange, occupying the digastric space, extending upwards on the jaw and forwards beneath the symphysis; the swelling fluctuated on the surface, was fixed and hard when grasped, painful to the touch, and extended along the internal side of the jaw, causing a hard tumour, which could be felt through the mouth.

I submitted the case to consultation, and it was decided that the patient should get the chance of operation. He was informed of the risks of the operation, and the probability of return of the disease; but he was most anxious, notwithstanding, that something should be done to relieve him from pain even for a time.

Operation.—On Monday, 12th of October, assisted by my colleagues, I proceeded to remove the diseased mass as follows:—The patient was placed on the operating table and chloroformed. I made an incision from the angle of the jaw across the submaxillary space, to the under surface of the symphysis, and with a scalpel dissected the integuments from the tumour. I secured the facial artery by passing a bent-eyed probe beneath it armed with a double ligature; the loop was cut, and each ligature separated and tied, the vessel being divided between them. A *silver* knife was next used to detach the submaxillary gland from its inferior attachments. A double tenaculum was then fixed firmly into the tumour and drawn forwards, to enable me to detach it posteriorly. A very large artery spouted from the bottom of the cavity, which was secured in the artery forceps and tied. I used my fingers frequently during the operation, and succeeded in removing the entire submaxillary gland. The jaw, which was fully exposed, was found to be diseased. I accordingly extended the incision from beneath the symphysis to the under part of the red margin of the lip, and with a small saw divided the lower part of the bone, and made a similar section beneath the angle; and then, by using the saw in the long axis of the bone, I was enabled to remove the lower and diseased part, *leaving the teeth and alveolar process.* The blow-pipe gas cautery was applied freely to the large cavity to destroy any diseased part which might remain. The patient bore the operation remarkably well.

The wound was dressed with carbolic acid, and was syringed several times daily with a solution of carbolic acid. The patient made an excellent recovery, and returned to the country.

CASE 2.—*Cystic tumour of lower jaw; operation; recovery without deformity.*

L. S., aged nineteen years, a resident in the city, consulted me at the City of Dublin Hospital, in the autumn of 1868, about a swelling, situated on his lower jaw, which he first observed seven months previously, and thought it was a gumboil. His jaw was considerably enlarged on the left side, and on looking into his mouth I observed a tumour (corresponding to the outer side of the molar teeth) about as large as a small egg; there were two stumps of decayed teeth. The tumour fluctuated, and a thin shell of bone could be distinctly felt surrounding the tumour. I punctured the cyst with a large exploring needle; an oily glairy fluid escaped. The fluid recollected rapidly, and on Monday, the 1st of November, 1868, I operated as follows:—

The patient was seated in a stout armchair, with his head resting against an assistant's chest. I raised the anterior wall of the cyst with a tenaculum, and removed with a scissors a circular piece; a quantity of oily glairy fluid escaped. I passed my finger into the cavity, which extended deeply into the jaw. A fang of a tooth was felt in the cavity, and was removed by means of an elevator; there was very little hæmorrhage. The cavity filled up quickly, leaving no deformity.

CASE 3.—*Cystic tumour of right antrum protruding the cheek; operation.*

M. B., aged thirty-six years, a washerwoman, consulted me, in August, 1868, about a swelling of her right cheek, which, on examination, I found to be a cystic tumour of the right antrum. I operated as follows:—The upper lip being raised, I plunged a small trocar into the tumour and drew off a glairy fluid.

CASE 4.—*Large "Epulis" on Superior Maxilla removed without any incision through the cheek; successful result.*

J. J., aged forty-two years, a native of Wexford, was admitted into the City of Dublin Hospital, on the 16th October, 1868, suffering from epulis of right upper jaw.

History.—Patient always enjoyed good health; is married, and had thirteen children. About eight years ago she felt a soreness on the gum, corresponding to the second molar tooth. A small lump soon appeared on the part; it was removed by a medical gentleman. It reappeared three years since, and was again removed by operation. A year before patient's admission into hospital it reappeared for the third time, and loosened her teeth. Patient never suffered much pain in the part.

Appearance of patient and tumour on her admission into hospital.—She is pale, but otherwise healthy looking; right cheek prominent. On opening the mouth a large "Epulis" is observed occupying the right side of the upper jaw, corresponding to the last four teeth, which are loose. The tumour is not painful, nor does it bleed when touched; it is of firm consistence, and unattached to the alveolar process.

Operation performed in following manner:—The patient having been seated in a stout arm-chair, with his head resting against the breast of an assistant, the loose teeth were extracted. The cheek was then forcibly retracted by means of a special instrument. An incision was made with a stout scalpel through the gum in front of the tumour, and then a fine-bladed saw was introduced, and the alveolar process divided. A similar incision was made behind the tumour, and the entire mass was removed by one stroke of a powerful cutting pliers. The blow-pipe gas cautery was next applied to the part to arrest the hæmorrhage and destroy any part of the disease which might remain in the gum.

The patient made a good recovery.

M. **Harry Stapleton** (M.B., M.R.I.A., &c., Surgeon to the Jervis' street Hospital), gave the

HISTORY OF A CASE OF MEDULLARY CANCER.

Robert Grogan, aged fifty-two years, married, and having a family, had, as he reports, been in perfect health until about eighteen months ago, when he noticed a small tumour, about the size and shape of a walnut, in the gluteal region. He sought no advice for some time afterwards, until alarmed by its increasing size, he applied to a medical practitioner in his neighbourhood, under whose care he remained for a few months. On the 13th of October, 1868, he was admitted into the Jervis street Hospital, under my care. The size and shape of the tumour was now about the size and shape of half-a-cocoa nut, cut across its long diameter. It was somewhat hard and tense, but still there was a sense of fluctuation, as of some thick liquid. The integuments covering the tumour were of a pinkish hue, but on its apex there was a dark patch, in diameter about one and a quarter inch ; in the centre of which there was a black spot about an eighth of an inch in diameter, and which the patient accounted for, by saying that an instrument had been stuck into the tumour, and blood only escaped. On the following day he was seen, in consultation, by my colleagues. The nature of the tumour being suspected, and inflammation having now attacked it brought on, probably, by his long journey to town, it was resolved that nothing further should be done than to endeavour to allay the inflammation. The tumour daily increased in size, and in about a week, the part of the integument which had been discoloured sloughed, and a smart hæmorrhage took place from a protruded substance, much resembling the convolution of a much congested brain. The hæmorrhage was arrested by the application of charpie, moistened with spirits of turpentine, and retained *in situ* by digital pressure. The patient, from this time, had to be confined to the recumbent position, for, if he left the bed he occupied, to pass to one beside him, which was newly made, hæmorrhage to an alarming extent immediately took place.

The tumour formed by the protruded brain-like substance rapidly increased, from day to day, until it had reached the size shown by the cast (exhibits the cast). In its longest diameter it (the cast) measures thirteen and a half inches, in its shortest twelve inches. Indeed, the size shown by the cast I may say is not faithful, as it was taken after death, when the tumour had considerably collapsed.

The patient gradually became much exhausted, and on the evening of the 7th of November, 1868, having sat up in his bed, he vomited about a pint of blood, then fell back and expired.

On *post-mortem* examination, there were found about two pounds of blood in the stomach. The blood having been removed and the stomach washed, two ulcers were found, one about the size of a florin, and the other, about the size of a shilling. Their seat was the lesser curvature of the stomach, near its pyloric orifice. In the centre of the larger ulcer may be seen the ulcerated vessel from which the hæmorrhage had taken place, and which was the immediate cause of death. It is worthy of remark, that during the period the patient was in hospital he never complained even of any uneasy sensation in his stomach.

The tumour, on examination, was found not to have any distinct investing membrane. On being cut into, its colour varied, some parts being white, some grey, and some dark brown.

Its consistence, likewise, differed much in various portions, some being as solid as brain, others gelatinous, and some, again, resembling extravasated blood. No vessel of large size was found to enter the tumour, which lay upon the sciatic nerve, but had no connection with it, nor did it enter the pelvis.

In the gluteal muscles were found many bodies, from the size of a kidney bean to that of a small millet seed. The larger were covered with a very fine investing membrane, and they were situated between the muscular fibres. When cut into and scraped, they gave a thick and milky juice, which, being examined under the microscope, was found to consist principally of fine granular matter, a few mother and caudate cells, a great number of free nuclei and oil globules.

INEBRIATE ASYLUMS.

In pursuance of our intention to inform our readers on the condition of Inebriate Asylums in other countries with a view to their introduction into Great Britain, we have put ourselves in communication, in the first instance, with Dr. Day, the medical superintendent of the best known institution of this class, that at Binghampton, in the State of New York. We published in a recent issue, (Feb. 10th, 1869,) some statistics which appear to us worthy of being reprinted as of further observations :—

We learn from the *New York World* the following facts :—

> Since May, 1867, when the new life of the Asylum began' 310 patients have been received, 230 of them coming in during the year which has lately closed. Of these 220 have been discharged and 82 remain. Of guests thus entertained 146 had wives and 164 unmarried, showing that celibacy is either an incentive to hard drinking, or that hard drinking causes men to avoid family responsibility. The habitual drunkards number 163, the periodical ones 147. Some came of themselves for voluntary relief ; others were brought by friends. Suffering from one or another form of delirium were 96 ; 34 had convulsions ; 73 were in general good health, but sought escape from the temptation that did so easily beset them ; and 101 were set down as cases in which this legacy of moral weakness had been inherited. After one trial of the beneficent influences of the asylum, 113 left it thoroughly reformed, eleven returned after one relapse, and four after a second. With no hope of retrieval 25 were expelled ; nothing definite could be ascertained about 68. Four died and three had to be transferred to the madhouse—insane beyond the chance of recovery.

These results of examples will appear the more remarkable when it is understood that they are obtained without the intervention of the law, or without interfering with the jealously guarded liberty of the subject at all. It is true that the American Government have recognised the urgency of the movement, and have passed a law which assimilates the condition of the confined drunkard to that of a lunatic.

> The Committee of an habitual drunkard, duly appointed under the provisions of the Laws of this State, can place such

habitual drunkard in the Asylum, and authorize his detention, under such restraint as may be necessary to prevent his escape.

Chapter 266 of the Laws of this State, passed March 31, 1865, entitled "An Act for the better Regulation and Discipline of the New York State Inebriate Asylum, provides as follows:

> "Sec. 4. Any Justice of the Supreme Court, or the County Judge of the County in which any inebriate may reside, shall have power to commit such inebriate to the New York State Inebriate Asylum, upon the production and filing of an affidavit or affidavits, by two respectable practicing physicians, and two respectable citizens, freeholders of such County, to the effect that such inebriate is lost to self control, unable from such inebriation to attend to business, or is thereby dangerous to remain at large. But such commitment shall be only until the examination now provided by law shall have been held, and in no case for a longer period than one year."

We learn from Dr. Day, however, that the loose wording of this law and the inevitable cavils of lawyers have made it practically inoperative. Dr. Day writes thus :—

> "I do not pretend to restrain patients here by law, and I have nevertheless but little trouble in retaining them in the institution. An inebriate who would require a prison to keep him, could not be benefited by an asylum, a gaol with hard labour would be the most fitting place for him. The work of reformation or cure cannot be carried out under compulsion. We must appeal to the moral nature, and, if possible, develope latent moral character."

We extract the following from the rules of the asylum :—

> Upon entering the Institution, the patient, or some friend in his behalf, will be required to execute a bond or obligation, to be signed by himself, and one responsible surety, residing within the State, in the following form :
>
> "In consideration of . . . . . . being admitted as a patient to the New York State Inebriate Asylum, the undersigned promise the corporation of said Asylum, to pay to the Superintendent thereof, at said Asylum, quarterly in advance, on the first day of each successive three months, the sum of . . . . . dollars per week for each week and fractional part of a week of such succeeding three months, for which said patient has been or may be admitted, for the medical treatment and board of said patient. Also, to pay for extraordinary medical and other extra attendance, should such attendance be necessary ; to provide or pay for such requisite clothing and other articles as the Superintendent may deem necessary for the health and comfort of said patient ; to remove said patient when discharged ; to reimburse such necessary expenses as may have been incurred in case of his death ; and to pay all damages which may be committed by said patient upon the property of said Asylum."
>
> All persons, in becoming inmates of the Institution, bind themselves to observe and obey the By-Laws and rules governing the internal affairs of the Asylum. Any deliberate violation of them will be considered good cause for removal from the Institution.
>
> No patient will be received for a less period than three months, nor, in the first instance, for a longer term than one year. In order that the benefit to the patient may be permanent, the Superintendent and physician will, upon a full examination of each case, determine the length of time for which the patient will be received.
>
> FREE PATIENTS.—Any Inebriate having a permanent home within the State, whose circumstances render it necessary, may be admitted to a free bed, at the discretion of the Committee on Management and Discipline. If a free bed is applied for, the applicant or his friends must give satisfactory proof of the inability of the applicant, or of his family, to remunerate the Institution for his support during his stay therein. And in addition to such proof, the applicant must furnish the certificate of the County Judge of the County where he resides, and if a resident of the City of New York, the Mayor of said city, that he is a proper person to be received into said Institution, as a free patient.
>
> PAYING PATIENTS.—All other persons will be charged according to the rooms, attendance and accommodation furnished them, taking into consideration their ability to pay ; and in all cases payment in advance, for three months, will be required.

The administration of medicine is indicated on the first admission of a patient for, as a rule, great prostration exists with all sorts of symptoms depending on the condition, age, temperament, and general health, but when the system is restored to efficiency, then begins the work of reformation.

It would seem that the system of reducing gradually the dose of stimulants is totally repudiated, and without the least ill-result. Dr. Day writes :—

> "We insist on total abstinence from all that can intoxicate, upon this rests all our treatment or hope of cure—without this foundation we build in vain—not one drop of alcohol in any form must pass their lips. Even time will never erase the alcholic diathesis, for there are cases in which one drop of liquor upon the tongue will seem to excite every fibre in the system, the fire is lit up and drunkenness is the result. I find that most men can practice total abstinence with perfect ease, but moderation is to them intemperance."

The results of the management of the Asylum by Dr. Day, represent a period of only eight months, and, are therefore, necessarily imperfect. We leave their elucidation of them to his own words, which we quote from the first report of the Institution issued on the last day of 1865 :—

> When I assumed direction of the Institution in May of the present year, it had, for reasons with which I think the public are well acquainted, been closed for several months against the reception of patients. The Trustees had availed themselves of the opportunity thus afforded to repair that portion of the building uninjured by the fire.
>
> It is but fair also to mention, that I have found in my intercourse with the public—by correspondence and otherwise—an element of dissatisfaction with and distrust of the Institution, which is a legacy left to me by the past management of the Asylum, and of which I do not complain, as I was led to expect it. It will not then of course be expected that the history of the past eight months will be wholly satisfactory, as a demonstration of the success of any particular theory, or as fruitful in large results as might be presumed from the magnitude of our plan of operations, and the vast expenditures during the past ten years on the Asylum building. An array of statistics commensurate with the extent of our works, must be looked for in a future report, when the management shall be more independent of distracting accessories, the Asylum more firmly established in public confidence, and a proper knowledge of its character more widely extended.
>
> More than forty years ago the eminent Superintendent of the Insane Asylum in Worcester, Massachusetts, Dr. Woodward wrote a pamphlet on the subject of an Asylum for Inebriates, in which he urged upon the people of that commonwealth the establishment of such an Asylum. At a later period than this (1841) the Legislature of that State was memorialized in favour of establishing an Asylum for this unfortunate class of men.
>
> So slow were the people of that State to see the necessity of such an Asylum, that an Institution was not established until the year 1857, and then in a very small way, but it has grown to be an Institution loved and cherished by the people of that State above any and all of its noble monuments of charity and benevolence.
>
> The citizens of the State of New York have given abundant evidence of their desire that an Asylum for the treatment of the inebriate should be established.

(To be continued.)

◆

SCOTLAND.

PROFESSOR SYME.

WE regret to state that this distinguished surgeon has had a serious attack of a paralytic nature, but not depriving him of his mental powers.

EDINBURGH UNIVERSITY.

THE University Court met on Monday last, the 5th inst.—present, Principal Sir Alexander Grant, Bart., in the chair ; Mr. Gordon, the Lord Provost, Mr. Macknight, Mr. Nicholson, the Rev. Mr. Phin, and Dr. Christison. The University accounts for 1867-8 were received and remitted to a committee. The Library report for 1868 was also received and remitted to a committee. On consideration of a report by the Senatus Academicus, showing that the finances of the University were in such a state as would admit of the sum of £4,500 of the capital of the General University Fund being applied to the purchase of an official house for the Principal, it was resolved, in exercise of the powers conferred by the alteration of ordinance No. 23, above referred to, to authorise the necessary expenditure. The opening by the Professor of Engineering of a summer class of surveying and levelling, with a fee of £3 3s., was approved of. The opening, by Professor Liston, of an elementary class of Hebrew, in the summer session, with a fee of £2 2s., was approved of. Arrangements recommended by Professor Playfair and adopted by the Senatus, under which Dr. A. Dalzell is to conduct the class of Practical Chemistry this summer, were approved of. Leave of absence to Professor Allman during next winter session, granted by the Senatus on the recommendation of the Faculty of Medicine, was approved of. Dr. Neil Arnott, F.R.S., the distinguished physicist, has written to Dr. Lyon Playfair, M.P., as member for the University, offering to place £1,000 in his hands to promote the study of Experimental Physics among the medical students of the University. The Senatus will immediately prepare a scheme by which the generous intentions of the founder may be best carried out.

ROYAL HOSPITAL FOR SICK CHILDREN.

DURING the month of March 73 patients were treated at this Hospital ; 384 were treated at the Dispensary ; and 89 were visited at their homes—in all 546 during the month. The directors have appointed Dr. R. Peel Ritchie, F.R.C.P.E., to be one of the ordinary physicians, Dr. Graham Weir having been appointed one of the consulting physicians. James Cumming, M.B. and C.M. (Edinburgh University), has been appointed resident-asssistant to the extra physicians in this Hospital.

ROYAL SOCIETY.

THE ninth ordinary meeting of this Society was held on the 5th inst.—Dr. Christison, president, in the chair. Professor C. Piazzi Smyth communicated a continued paper by Mr. William Petrie on "The Present State of the Sun's Distance Question." The other papers read before the Society were—"On Chemical Structure," by Dr. A. Crum Brown ; "Observations on the Temperature of Newly-Born Children," by Mr. T. J. Maclagan, M.D., Dundee ; and "On the Development, Growth, Situation, and Anatomy of the Human Fœtal Heart," by Professor Macdonald.

THE POOR OF EDINBURGH.

A LARGE number of influential ladies and gentlemen assembled at the annual general meeting of the Edinburgh Association for Improving the Condition of the Poor, which was held on Monday, the 5th inst., in Queen street hall. Lord Ardmillan presided, and in opening the meeting, delivered an opening address ; after which Dr. Hanna read the report. It gave an account of the origin of the society, and the course which had already been taken. It stated also, that the chief objects of the association were to educate the young ; to suppress beggary ; to promote sanitary improvement ; find work for the unemployed ; and to assist the struggling and destitute. The report was an interesting one. Among other things, the remarks on the sanitary condition of the city are worthy of notice. It says :—

> There is nothing more disgraceful to Edinburgh than the kind of houses in which so many of the poorest of its inhabitants reside. The reproach is one that ought as speedily as possible to be removed. The means are at hand for doing so. By the Provisional Order of 1862, and the Public Health (Scotland) Act 1867, ample powers are put into the hands of our municipal authorities. They can prevent overcrowding in rooms. They can enforce proper drainage, ventilation, and supply of water by the landlords. They can order all ruinous and dangerous tenements to be rebuilt or repaired, and in default thereof can take possession of and remove them. They can cause all nuisances injurious to the public health to be done away. Why, then, are so many cellars and garret-holes and dens, such as farmers would not put their cattle in or gentlemen their dogs, inhabited by human beings ? Why are so many ranges of buildings without sufficient light or air or water ? It is for such an Association as this, as it is for the community at large, to invite them, as we thus do, to put forth vigorously the powers with which the Legislature has clothed them, and if they do so, to encourage and support them to the uttermost.

The report was adopted, resolutions were passed, approving the course pursued by the Association, and after a vote of thanks to Lord Ardmillan for presiding, the meeting separated.

ABERDEEN ROYAL INFIRMARY.

AN abstract of the collections, contributions, legacies, &c., given to this institution during the year ending 31st March 1869, has just been published. Mr. Carnie has made the abstract, by which it will be seen that the interest taken in this institution has not abated, but rather increased—the total amount subscribed during the year, as shown, being £2,863 14s. 5d.

SANITARY MEASURES.

THE local authorities of the parish of Beath, held a meeting lately to take into consideration the sanitary condition of the village of Cowden-beath, where for a long time past fever of a very malignant type has constantly prevailed, and caused much distress, and proved fatal in many cases. The death-rate of the village has, in consequence, increased so much of late as to draw attention to the matter, it being generally admitted that the drainage and water supply are grossly deficient. It was agreed upon to proceed immediately with the draining of the village, and the bringing in of an adequate supply of water, the probable expense of which scheme, it is considered, will not exceed £500.

BANQUET TO THE LORD ADVOCATE OF SCOTLAND.

The Right Hon. James Moncreiff, Q.C., M.P. for the Universities of Glasgow and Aberdeen, was on Saturday night last entertained at a banquet in St. James's hall by London friends and constituents. The chair was occupied by the Duke of Argyll, at whose right hand was the guest of the evening, and among those present were :—The Earl of Airlie, the Hon. A. Kinnaird, M.P. ; Colonel Sykes, M. P. ; Lieutenant-General Sir A. Wyllie, K.C.B. ; Mr. W. Finnie, M.P. ; the Earl of Minto, Lord Rollo, Lord Campbell, Mr. F. Dundas, M.P. ; the Solicitor-General for Scotland, M.P. ; Mr. W. P. Adam, M.P. ; Mr. Peter M'Lagan, M.P. ; Mr. James Merry, M.P. ; Mr. W. E. Baxter, M.P. ; Mr. Edward Ellice, M.P. ; Mr. David Robertson, M.P. ; Dr. Lyon Playfair, M.P. ; Mr. Æ. W. Macintosh, M.P. ; Mr. Grant Duff, M.P. ; Mr. George Loch, M.P. ; the Lord Provost of Edinburgh, Mr. R. Sinclair Aytoun, M.P. ; Mr. H. Campbell, M.P. ; Mr. J. J. Grieve, M.P. ; the Hon. Charles Carnegie, M.P. ; Sir Robert Anstruther, M.P. ; Mr. R. A. Macfie, M.P. ; Mr. W. Graham, M.P. ; Mr. A. Orr Ewing, M.P. ; Mr. E. H. Craufurd, M.P. ; Mr. George Moffatt, Mr. Stevenson, M.P. ; Mr. Roger Eykyn, M.P. ; Mr. R. Jardine, M.P. ; Mr. W. H.

Maxwell, M.P.; Mr. T. B. Potter, M.P.; Mr. W. J. Fordyce, M.P.; Mr. G. Armitstead, M.P.; the Rev. R. Aspland, vice-chairman; Sir William Fergusson, vice-chairman; and the Rev. J. Kennedy, vice-chairman.

Dr. J. R. Wolfe has been appointed lecturer on ophthalmic medicine and surgery in Anderson's University, Glasgow. Dr. G. Weir becomes consulting physician to Edinburgh Children's Hospitals, and Dr. R. P. Ritchie, physician to the same charity.

◆

Notes on Current Topics.

Filthy Treasure.

The utilisation of sewage has again attained an incontestible triumph in the results attained at Aldershot camp. Three years ago the water-closet drainage was one of the difficulties of the locality, and one of the greatest dangers to the health of the troops. It cost a heavy expense to get rid of it, it polluted the air, and made the water undrinkable. A Scotch farmer, Mr. Blackburn, bid for and took it in a quantity of 170,000 gallons a day off the hands, if the phrase be admissible, of the authorities. He took his unsavoury bargain to 100 acres of stony and almost useless land, and got rid of it there. Into what did he turn its fragrance this the third year? Into six crops of Italian rye grass, selling at something like £10 a crop per acre, or say £5,000 nett for his 100 acres in the year. Will the public ever see for themselves these results, and learn better wisdom than walling up their rivers and polluting their air and drink by casting money value into their water courses. "Thus," says the *Times*, "in the space of three years the Aldershott sewage, which used to be poisonous matter, has been turned by skill into one of the most useful and fertilising agents that has ever been placed at the disposal of the agriculturist; and while the soil reaps the benefit of getting back the vegetable constituents which it has given forth, the camp authorities at Aldershot are saved all trouble and expense, and cease to pollute all the dykes and rivers round them. In plain terms, sewage, which used to be an endless trouble to be got rid of, is now likely, when properly applied, to be a source of continued prosperity to farmers who use it properly, even over the poorest lands. No greater proof of its success can be afforded than the Camp Farm at Aldershot, which in three years has been reclaimed from a sandy waste into a flourishing homestead."

Increase of Lunacy in France.

The attention of the Paris Academy has been called to this important subject by M. Lunier, who, being dissatisfied with the official statistics, had entered on a revision of them, which he submitted to the Academy. He found by his first observation that it appeared that the number of them had been increased fivefold in the interval between 1835 and 1869. In 1835 there were 16,000, or one in 2,016 of the population, and in 1869 the proportion had increased to 93,000, or 1 in 412.

M. Lunier attributed this apparent increase to an alteration in the method of taking the census, and to the annexation of Savoy, which brought a great number of Cretins and idiots into the calculation. His own personal calculation showed rather a diminution than an increase in the proportion. The number of admissions to special asylums has continuously increased since '35 from 3,947 to 12,317; but this increase has not been uniform throughout the whole period, and for some years it has not amounted to more than two per cent. He attributes the increase in mental disease to general paralysis and to alcohol, and he finds that a very much greater proportion of men than of women enter the asylums. Madness is not, as is usually believed, more common in woman than in man.

London Institution.

We have received information of a proposal to close the laboratory of this institution. We should hope this may not be done, for we have too few of such places in our metropolis.

Budleigh-Salterton.

We are glad to hear that the pleasant Devonshire retreat of Budleigh-Salterton is likely to have its one defect—insufficient supply of water—remedied. With plenty of good water, Salterton might rank with any of our health resorts. There is a good opportunity to attract many visitors both in summer and winter. We sincerely hope that now the question is seriously taken up it will be rapidly settled. Our own experience justifies us in predicting great progress for Budleigh-Salterton, an excellent resort for delicate people.

British Association.

Great preparations are being made at Exeter for the reception of the British Association for the Advancement of Science. It is hoped that Dr. Livingstone will be here in time for the meeting, in which case the success may be even greater than is anticipated. Exeter will give the Scientific Congress a reception equal to any it has met with.

New French Books.

Manual of Pathology and Histology, by Professor Cornil and M. Ranvier. Part 1—General Pathological Anatomy, with 168 figures. Price, 4f. 50c.

On the Various Forms of Nephritis, by Professor Cornil. A Thesis—pp. 175. Price, 3f. 50c.

On Empyema, by Dr. Damaschino. Thesis. Same size and price.

On the Alterations of Structure by Extractive Matter. 1f. 50c.

The Classification and Pathology of Chorea, by Dr. Leven. 2f.

On Polynsia, Diabetes Insipidus, by Dr. Launcereaux. 2f.

Gout and its Treatment, by Dr. Mourier. 1f.

The Pathology and Classification of Bronchitic Affections, by Dr. Hayem. 3f. 50c.

On the Re-section of the Coxo-femoral Articulation, by Dr. Good, surgeon in Confederate army. 2f. 50c.

On the Evacuant Action of Tartarised Antimony, by Dr. Davreux. 2f.

The Function of the Vascular System on Nutrition, and specially on that of the Heart, by Dr. Renoult. 3f. 50c.

Practical Treatise on Diseases of the Uterus, its Appendages, and the external Genital Organs, by Dr. Nonat. 2nd edition. 15f.

On Hernia of the Ovary, by Dr. Loumaigne. 1f. 50c.

Lectures on Refraction and Accommodation, by Dr. Ed. Meyer. 5f.

Treatise on Hygiene, by Dr. Motard, 16f.

Faradization at the Polytechnic.

Of all Professor Pepper's triumphs that to be now seen is most interesting to our profession. He has produced the most powerful induction coil ever seen, and the results must be of lasting importance. Faraday could scarcely have anticipated the perfection of mechanism which has thus made his discovery of so much greater value than was till just lately believed. Till now a coil fifteen inches long and four in diameter was called large. That would light up vacuum tubes, and give a spark of six or seven inches. Professor Pepper's new coil is a "monster," nine feet ten inches long and two in diameter. It gives a spark of twenty-nine inches, perforates plate glass five inches thick, and charges a Leyden battery, forty feet square, by three breaks of contact.

Some difficulties had to be overcome to make the monster manageable—for instance, at first the contact-breakers were destroyed in a moment on the first trial. But all has been overcome, and Pepper's monster may be seen in wonderful and terrible action, and will not only be a source of amusement to the many, but will, we cannot doubt, hasten many important discoveries.

The core of this new coil is of soft iron, formed by a bundle of straight wires, each five feet in length and ·0625 of an inch in diameter. The diameter of the combined wires is four inches, and the weight of the core is 123 lb. The primary coil is of copper wire of the highest conductivity, and weighs 145 lbs. The diameter of this wire is ·0925 of an inch, and its length is 3,770 yards. It is wound round with cotton, and makes 6,000 revolutions around the iron core. The secondary wire is 150 miles in length, and ·015 of an inch in diameter. It is covered with silk, and is wound into an outer coil 50 inches in length. The primary wire is insulated from the secondary by an ebonite tube half an inch in thickness, and the whole coil is enclosed in another ebonite tube and mounted upon substantial supports also covered with ebonite. The galvanic current for the primary coil is furnished by a Bunsen's battery of forty cells.

Dr. Richardson's Summer Course of Lectures.

On Tuesday, April 6th, Dr. Richardson inaugurated his Summer Course of Lectures on Experimental and Practical Medicine by a thoroughly original and deeply interesting discourse on the Effects of Temperature on the Animal Structures.

The important and novel fact, that animal tissues contract under the influence of a high temperature, was beautifully shown by an experiment in which the spasmodic contraction of a piece of muscle (which had been previously frozen), under the influence of a high temperature, was made the means of pulling the trigger of a pistol, so that the muscular contraction was demonstrated by the explosion of the cap upon the pistol as the hammer fell.

After the lecture, Dr. Sedgwick showed, under the microscope, the dilatation of the vessels in the web of the frog's foot under the influence of cold, and their contraction when heat was applied. The lecture was listened to by a numerous and attentive audience, and the experiments were most successful and interesting. The next lecture is arranged for May 4th, and will be on the Effect of Sudden Alternations of Temperature on the Animal System.

Sussex County Hospital.

The lamented decease of Mr. Blaker has caused a vacancy in the surgical staff of this hospital. Some of the local papers have published a statement that the appointment in question has always been given to members of a family or partners. Such ought not to be the fact. The surgeons to the hospital are general practitioners, and out of the 127 names in the Directory there can be no dearth of choice. These appointments ought all to be bestowed in a just manner. We commend to the Governors the example set in the formation of the Brighton Children's Hospital, on which we commented last week.

Brighton Drainage.

We observe that the *Brighton Examiner* denies the recent allegations of the *Lancet* on this point. At the same time, the *Examiner* evinces no desire to burk inquiry, but rather urges that it is impossible for the reputation of the town to suffer so much from free discussion as from any concealment of facts.

Small-pox and Vaccination.

The Report of the Medical Officers of the Small-pox and Vaccination Hospital shows that, in the course of the year 1868, 1,026 patients have been admitted into the Small-pox Hospital; and, of this number, 113 have died, being a mortality of 11 per cent. on the whole admissions. Of these 1,026 patients, 989 were suffering from small-pox, and 37 from various forms of acute febrile and, for the most part, eruptive diseases, not small-pox, but not easily distinguishable, in their early stages, from that disease.

The report also gives a sketch of the epidemic which has prevailed in the last five years, from which we extract some details:—

> "The epidemic of small-pox, which commenced in the autumn of 1862, would seem to have begun in the eastern parts of the metropolis—in Whitechapel, St. George's-in-the-East, Ratcliff, &c.; but it soon spread, and by the beginning of 1863 was, with perhaps one or two exceptions, nearly equally prevalent in all parts of London. It reached a high degree of intensity by May and June, 1863, soon after which it began to decline, and continued doing so until the middle of 1864, at which time (although still very largely in excess of what is observed in non-epidemic periods) the monthly admissions into the hospital had fallen to less than a half of what they had been in the corresponding months of 1863. In the winter of 1864-5, the epidemic evinced increased activity, and the lowest monthly admissions in 1865—namely, 75 in December—were but a trifle less than the highest monthly admissions in 1864—namely, 83 in January and April. The disease became more and more prevalent in 1866. In that year 2,069 patients were admitted into the hospital—a very much larger number than had ever been received within the same period, and exceeding by more than 25 per cent. those admitted in 1863, the year of largest admissions in the whole history of the hospital prior to 1866. The epidemic continued in full activity during the whole of 1867, and up to May, 1868, after which it very rapidly declined, and ceased in July, or the beginning of August, 1868.

The admissions into the Small-pox Hospital in August, 1868, were more than 20 per cent. less than they had been in any month since the commencement of the epidemic.

In the five years and nine months—from November, 1862, to July, 1868, both included—during which the epidemic continued, 8,376 patients were admitted into the Small-pox Hospital. They were distributed as follows:—

1862—November and December ...	207
1863	1,537
1864	836
1865	1,249
1866	2,069
1867	1,626
1868—January to July	852
	8,376

The disease at the commencement of the epidemic was severe, and the mortality proportionately high, but it became gradually milder and more benignant, and consequently less fatal. The general mortality diminished from 17 per cent. in 1863 to 11 per cent. in 1868; the mortality in unvaccinated subjects from 48 per cent. in 1863 to 34 per cent. in 1868; and that in vaccinated subjects from 9·9 per cent. in 1863 to 5·6 per cent. in 1868.

The progressive diminution in the severity and mortality of the disease will be better shown by the following table. As a standard for comparison we may take the mortality in 1861, a year wholly uninfluenced by epidemic causes. In that year we had no deaths from superadded disease. The general mortality was 10·7 per cent.; the mortality in the unvaccinated 33·9 per cent.; and in the vaccinated 5 per cent.

	1863.	1864.	1865.	1866.	1867.	1868.
General Mortality	17·0	12·9	13·0	13·0	12·66	11·0
Mortality in the unvaccinated	48·0	36·0	38·0	35·7	36· 8	34·0
After deducting superadded disease	47·0	35·0	..	..	..	..
Mortality in the vaccinated..	12·0	8·7	7·4	7·3	8·29	6·2
After deducting superadded disease	9·9	7·9	7·2	6·7	7·46	5·6

Brain Work in England and its Results.

We publish elsewhere some very serious facts respecting the increase of insanity in France, and we have, unfortunately, to supplement them among ourselves by not less startling figures.

Among brain diseases, softening has of late years rapidly increased. In the ten years 1857-66, 11,685 deaths were registered in England and Wales. In the first five years, 1857-61, the average was 894, whereas in the second period of five years, 1862-66, the deaths averaged 1,443 annually. In 1857 the number of persons who died from softening of the brain was 775. Glancing at the mortality by all diseases of the brain and nervous system, including cephalitis, apoplexy, paralysis, insanity, chorea, epilepsy, convulsions, and other brain diseases not distinguished, it appears that the mortality in England and Wales to 1,000,000 of population has increased from 2,705 in 1857 to 2,912 in 1866. It is remarkable that the mortality from apoplexy and paralysis respectively has from the first been very nearly in equal proportions to 1,000,000 persons living, the proportion from apoplexy being 439 in 1857 and 490 in 1866, that from paralysis being 457 in 1857 and 500 in 1866. The deaths from insanity—21 per 1,000,000 of population in 1857, and 31 in 1866—do not indicate the number of deaths of persons in a state of insanity; large numbers of maniacs die of consumption and other diseases, and consequently appear under other heads. Of chorea the proportional number of deaths to 1,000,000 of population was only 3 in 1866. From epilepsy, to 1,000,000 living there were 118; and from other brain diseases undistinguished, 207 in 1857 and 267 in 1866.

The Meath Hospital, Dublin.

Rumour is busy within the profession in Ireland about the probabilities of the succession to the Surgeoncy of the Meath Hospital, vacated by the lamented death of Mr. Maurice Collis. That event has been so unexpected, and has occurred at such a period of the Session, that predictions of the result is rather difficult. Amongst many names mentioned as likely to be candidates are those of Dr. Mapother, Professor of Physiology in the Royal College of Surgeons, Dr. John Morgan, Professor of Practical Anatomy in the same School, and Dr. Mayne, son of Dr. Robert Mayne, the noted Irish physician, who died some years since. We believe the selection cannot be predicted with any confidence; but the fact of Dr. Mayne having been a candidate on two former occasions gives strength to his candidature.

Regeneration of Organs in Animals.

In the lower animals and even in certain classes of the vertebrates it is common to observe the growth of an organ or member which has been removed. It is interesting to know up to what point in the animal scale this mutilation may be effected with the probability that the organ may be reproduced.

M. Philipeaux has already proved by experiment that the spleen in the mammifers and the limbs in the salamander are not reproduced unless a portion of the organ be left in its place. New experiments on fishes have enabled this observer to generalise the results first established by him. He cut from the middle of the abdomen of gudgeons the left abdominal fin, and immediately placed the fishes in water under favourable conditions for health. Eight months afterwards the fins were completely reproduced.

In a second series of experiments he excised the fin with all the bones which support it. Some of the fishes died; but those which lived presented, eight months afterwards, a simple cicatrix, with no effort whatever at reproduction of the member.

The Health of Ireland.

Although, as we have remarked in another part of our issue, the Registration System in Ireland is utterly unreliable as affording any comparison with other countries, yet it is, we presume, no worse than it was last year, and we may take the statistics *quantum valiat* as representing the sanitary state of Ireland.

The deaths registered during the last quarter of last year show a decrease of 144 as compared with the corresponding quarter of the year 1867.

Scarlet fever of a malignant type was very prevalent throughout the country; forty-four of the Registrars refer to this disease.

In the Tallow District, of the 18 deaths registered, 8 resulted from scarlatina, and the Registrar observes that "I believe neglect in the sewerage department is a fruitful source of fever, *and to that cause I attribute the continuance of scarlatina.*"

In Broughshane, one-half of the deaths registered were caused by scarlet fever. Of the 54 deaths registered in Randalstown, 24 were from scarlet fever; and of the 44 deaths registered in Glenarm, 25 were referred to the same disease.

In some districts typhus fever was epidemic. The Registrar of Dysartmoon, states that "Fever, of the worst form of typhus, was very prevalent during the quarter. Four died in the district of the disease, and four in hospital."

The Registrar of Parsonstown observes that "There was more fever than usual, and of a more severe character. The common, continued fever which we generally meet with here, being in some instances replaced by typhus of a grave kind from the commencement." Typhoid or enteric fever prevailed in Cookstown.

Measles was epidemic in Belfast, Clonmel, Enniskillen, Lurgan, Moira, and Ballina.

Several Registrars report on the prevalence of whooping cough in their districts.

From Mohill the Registrar writes, "We have had an outbreak of fever, which must have been caused by the filthy and neglected state in which the inhabitants generally keep their yards, &c., and also by the imperfect drainage and sewerage of the town; for though the facilities for improvement in a sanitary point of view are very considerable, from its position, yet I regret to have to state that such has not been taken advantage of."

The Galway Registrar reports favourably of the sanitary condition of his district: he says, "The sanitary arrangements lately introduced, particularly the waterworks, which give to the poor an abundant supply of pure water, have contributed to the healthy state of the district."

Local Non-Government.

The final cause of the diarrhœa epidemic which has been for some time prevalent in Leicester has at last been traced to the ineffably stupid system of cesspools. These receptacles, as generally constructed, are nothing but ingenious arrangements for filtering the sewage solution into the drinking water of the public, and it turns out that in Leicester it is a favourite theory that you have only to hide the sewage out of your sight and you thereby dispose of it most effectually and innocuously. The poor of Leicester have paid the customary toll to this idea of an increased death-rate with, we presume, as much effect on the minds of the local sanitary authorities as if it were only the income tax.

For their instruction we quote the following extract the Sanitary Record.—

A significant entry in the Government Return appears under Tamworth, vix.: "No works of sewerage or water supply have as yet been commenced under the Local Government Act; plans and estimates for the purpose were obtained, but a great clamour has been raised in the town against the proposed works, in consequence of which nothing has been done." Unfortunately for the health of Tamworth, the matter did not rest here. In the Registrar General's last Quarterly Report of 1817 it is recorded:—"There has been much fever in the borough of Tamworth. The town is in a very bad state, abounding with nuisances, none of which are ever removed by the authorities. The mortality bears but a small proportion to the amount of sickness occasioned by the extremely filthy condition of the town. Tamworth appears again in the third Quarterly Report of 1868 with a death-rate enhanced two-fold, the chief losses, as is usual under these conditions, being of children under five years of age. Once more, Tamworth appeared about the same time in the Birmingham conference with the following notice attached to it:—"In Tamworth, where the table shows the well-water to be excessively bad, disease is fearfully rife. One medical man informs me that from 'his own knowledge, typhoid and diarrhœa are exceedingly prevalent,' that in one house where one of the above waters was used, 'he had about eighteen months ago ten cases of typhoid.' He adds, that there was considerable improvements in the health of those who were at the trouble to obtain pure water." If Public Health be in reality, as it has been dedeclared to be, Public Wealth, "if these five words do, indeed, form an adage of momentous import and stern truth," if it be true "that the gain of lives annually would pay ten times over the cost of all the exertions that might arise to secure them for life and for their country," then what has been the cost of Tamworth to the State and the community at large, and how many more Tamworths are there in the country?

Liebig's Extract of Meat Company.

Columbus had his theories disregarded by the knowing ones of his time. The history of useful discoveries forms a record of struggle against prejudice, ignorance, and scepticism. Discoveries that have illumined the firmament of philosophy, that have opened up the hidden treasures of science and of letters, that have a thousand-fold increased the universal store of learning, and that have trebled the wealth of nations, had to languish—neglected in their infancy, derided, contemned, and scorned. Indeed, few, if any of the men to whose genius mankind and civilization are largely indebted, live to see the triumph of their principles, or to obtain the reward their laborious study should receive—rather a sad reflection for those who would press still further the limits of discovery.

Among the human benefactors of the present century, Baron Liebig takes a prominent place. He, unquestionably, is the most "practical thinker" of the age. To him the broadly-stretched human family are largely indebted; and much as the debt has been acknowledged by the studious, the scientific, and the thoughtful of the present time, the crowning wreath has yet to be placed on his brow—at no distant day, nevertheless.

One of the last "practical thoughts" of Baron Liebig has been directed to the utilization of the immense herds of sheep and of oxen that swarm the plains of South America. To utilise the vast amount of animal flesh—heretofore permitted to become a pestilence over the boundless prairie (for the skin and what it displayed on the outer surface—fleece or hair, as the case might be—had been considered the only valuable portions of the animals)—by reducing it by a certain process to a state sufficiently portable for exportation to countries where, for want of animal food, the peoples languish, has been the grand idea of the great thinker. But it has become more than an idea. Into a broad, bold, and indisputable fact—tangible and ungainsaying—it now resolves itself.

The Liebig's Extract of Meat Company, whose manufactories for the utilization of the animal flesh aforesaid—by converting it into an extract, a *single* pound weight of which extract contains the essential qualities for human sustenance of *thirty-five pounds* weight of *boneless* beef, free from gelatine and from fat; light, palatable, strengthening, and sustaining; suited for the sick room, the infant, the adult, and the aged and infirm—are at Uruguay and Entre Rios (Argentine Republic), and whose London offices are at Mark lane, now places in our markets the priceless boon which we have for so long sought—cheap beef; and it remains with ourselves, by supporting in a *practical* manner the laudable and indefatigable exertions of those who have commenced this great undertaking for the people's good, to what extent it is to be further carried.

On Saturday evening last a number of gentlemen were entertained at Francatelli's St. James's Hotel, Piccadilly, by the Directors of the Liebig's Extract of Meat Company. As stated in the *carte*, the "test" dinner was "intended to show the value of extract of meat as a meat-flavouring ingredient, and as a general aid in cookery, thus illustrating the part which this new article of food may play in the meat supply of this country."

The guests consisted principally of gentlemen well known and able workers in the fields of medicine, science, art, and letters. The Company was represented by Dr. Thudichum and Messrs. Boutcher and Gunsher. The principal speakers were the Chairman and Vice (Messrs. Boutcher and Gunsher), Dr. Richardson, Mr. Murphy—whose eloquence, intersprinkled with sprays of satirical humour, fun, and good sense, was scarcely unequalled by his good looks and portliness, kept the company in a continued feast of soul—Mr. Ruskin, R.A., Mr. Woods, Dr. Routh, &c., &c.

The banquet, for such we shall call it, was served with that correctness and profusion which has made the name of M. Francatelli famous as a caterer of culinary art, and successfully and practically settled, to the satisfaction of the entire company (and, by-the-by, to that of the caterer, M. Francatelli, who, on being called, distinctly stated that the meat extract *should* necessarily become a leading material wherever large culinary arrangements were required, on account of its richness, durability, portability, and cheapness), that Liebig's extract of meat is a success and a boon, for which European nations, and England in particular, should feel grateful, obliged, and—more.

We append *carte*, by reference to which our readers may have an idea to what extent Liebig's beef extract was employed on the occasion:—

Menu du Diner
A l'extrait de bœuf, &c., de la Compagnie Liebig.

Potages.—Le consommé à l'extrait de bœuf (la soupe de ménage du Baron Liebig); à la téte de veau en tortue.

Poissons.—Le turbot à la vatel; les rougets aux fines herbes.

Entrées.—Les cailles en caisses au gratin; les cotelettes de mouton piqués en chevreuil; les filets de volaille à la duscelles aux pointes d'asperges.

Relevés.—Les poulardes truffées; le jambon aux feves; le filet de bœuf à la jardinère.

Second Service.—Les canetons rotis; les petits pois; les salades de thon; les gellees de peches; les savarins aux abricots; les souffles glaces.

For all the soups, fish, and made dishes, Liebig Company's Extract of Meat will be employed in lieu of the ordinary stock, the proportions used being one ounce of the extract as a substitute for the stock produced by about two pounds of lean beef.

The Vice-Presidency and Council of the Royal College of Surgeons in Ireland.

The Vice-Presidency of the College, which will occur in June next, by the outgoing of Mr. Porter, the President, and the elevation of Mr. Macnamara to the Chair, will be sought, we understand, by Dr. Albert Walsh, Surgeon to the Adelaide Hospital, and for many years a Councillor of the College. Up to Saturday last Mr. Stapleton had been also a candidate, but we presume that his election to the Examinership on that day will, if it should be ratified at the election in May, cause the withdrawal of his claim on the Vice-Presidency. At present no other candidate has, as far as we know, declared himself, but it is not impossible that on the first Monday in June there may be other claimants for the honour of the vice chair.

The lamented death of Dr. Mackesy, of Waterford, creates a vacancy in the Council, on which it would be as yet premature to speculate. Dr. Morgan, Surgeon to Mercer's and the Lock Hospitals, and Professor of Practical Anatomy in the College, and Dr. Kirkpatrick, Medical Officer of the North Union, will seek the suffrages of the Fellows.

Election of an Examiner in the Royal College of Surgeons in Ireland.

The College and its Council assembled, as we announced last week, on Saturday for the election of Examiner in the room of the late Mr. Collis, the election having been necessarily held at an early date to meet the requirement of the primary examination, which commenced yesterday. The short interval between the declaration of the vacancy and the election did not reduce the competition, for six candidates offered themselves. The chair was occupied by the President at three o'clock, and a majority of the Council and some Fellows were present. The leading competitors were Mr. Stapleton, Surgeon to Jervis street Hospital, and formerly for many years an Examiner; and Mr. Philip Crampton Smyly, whose candidature we noticed last week; and with them the following gentlemen competed:—Dr. W. Roe, Assistant Physician to the Coombe Lying-in Hospital; Dr. Charles Moore, Physician to one of the Districts of the South Dublin Union; Dr. Robert Murney, and Dr. Gogarty.

In accordance with the Charter of the College, seven gentlemen were drawn to elect, and the lot fell upon the President, Mr. Porter; the Vice-President, Dr. Macnamara; and Messrs. Irvine, Wharton, Butcher, Labatt, and Elliott, who were duly sworn and retired to consider their choice. On their return, the President announced Mr. Stapleton elected. The regular annual election of Examiners will take place in May, when a full Court, probably of its present members, must be elected.

Death Registration in Ireland.

It is subject for much regret to the profession in Ireland, no less than to the public, that the registration, which was entrusted to the medical officers of dispensaries in preference to the police, as proposed by Mr. Cardwell, shows itself to be totally unreliable on a comparison of the death-rates for Ireland and England. The Quarterly Return of the Registrar-General for Ireland notices this state of things, and condemns the working of the system on apparently very sufficient grounds.

The number of deaths registered in Ireland during the last quarter of last year was 20,528. This shows a proportion of 1 death in 67·5, made up of proportions varying from 1 in 30 in Belfast down to 1 in 139 in Newport, Tipperary. The established ratio in England is about 1 in 40 or 45, so that, if the salubrity of each country be the same, it is evident that more than a fourth of all the deaths are neglected, and never returned to the Registrars at all.

In the matter of births the evidence is as strong, the ratio for England being 1 in 30, and for prolific Ireland only 1 in 42, when probably, if all the births were duly recorded, the proportion would be reversed.

The Registrar-General says, "the registration of marriages is still more unsatisfactory."

In the interest of the Poor-law Medical Officers of Ireland, we greatly regret to be obliged to record these facts. The Legislature confided an important duty to the profession, and refrained from placing a penalty on its non-performance, and it will be greatly to be regretted if it be necessary to enforce registration or to place it in other hands.

Solvents for Croupal Membrane.

The *Gazetta Medica di Lombardia* records the results of many experiments on the solubility of false membrane. The specimens selected were as nearly as possible of the same consistence and of a gramme in weight.

1. Solution of iodide of potassium, one in ten. At the end of fourteen hours the false membrane was reduced to filaments.
2. Sulphate of zinc, same strength. After fourteen hours membrane had shrunk.
3. Bromide of potassium. After fourteen hours membrane was transformed into a pulpy substance.
4. Chloride of sodium, chloride of barium, and hyposulphate of soda gave same result.
5. Cyanide of potassium. Complete solution in fourteen hours.
6. Borax. Membrane became yellow and tough.
7. Muriate of ammonia. No result.
8. Sulphate of iron. No result.
9. Carbonate of potash. Complete solution.
10. Sulphate of soda. No result.
11. Chlorate of potash. In three hours became like charpie.
12. Lime water. Same effect in same time.
13. Bicarbonate of soda. Perfect solution in three hours.
14. Nitrate of silver, one in ten. Hardening and contraction.

The Queen visited St. Bartholomew's Hospital last week.

A severe form of pleuro-pneumonia has broken out among the cattle in several parts of the country.

Dr. J. J. Phillips has obtained the Assistant-Physiciancy at the Children's Hospital.

Mr. Tay is a candidate for the Assistant-Surgeoncy at the London Hospital, and Mr. B. Squire, M.B. Lond., for the Skin Department at Charing-cross.

A subscription has been commenced, as will be seen on reference to our advertising columns, for the purpose of defraying the legal expenses of Dr. Hardwicke in contesting his rights to the West Middlesex coronership.

The Children's Protection Society of Lyons, desirous of encouraging mothers in nursing their own children, have announced that they will award at their meeting in 1870 a prize of 300 francs to the author of the best essay "On the influence of lactation on the moral and physical health of the mother, and the accidents and diseases which may result from the suppression of that function."

◆

IN MEMORIAM.

MAURICE COLLIS.—A LAUREL SPRAY AMID THE CYPRESS.

When I became a medical student the late Mr. Collis was Junior Surgeon and Medical Registrar to the Meath Hospital. That was in the time of Crampton, Porter, senior (and junior), *the* Smyly, Rhind, and others whose names I omit, as I hav'nt the slightest reason to remember them with that affection which *should* exist for aye between teacher and pupil. It was ere Wharton's time, and prior to Hudson's and Macnamara's election.

Then, and perhaps at present, students received from their teachers cards that admitted them to the sessional meetings of the Pathological Society. When I became a senior student I sought for, and obtained, a Pathological Society's admission card, my ambition being to receive at the end of the session the coveted certificate of that Society, given only to those that attended a fixed number of its meetings. The meetings I religiously attended until towards the close of the session, when I was compelled to remove to the country. Even then I determined to secure my certificate, so on two occasions, at a fare of 10s. 6d., and at railway speed, I *sped* to catch those Saturday evening meetings of the Society. I won my prize—at least I thought so—and even had, I considered, a "meeting to spare;" but, lo! red tape in the fingers of Mr. Robert Smith, Secretary (and everything) to the Pathological Society, tripped me up! On two occasions the paper slip given by me (the check on my attendance) displayed my name written in the unassuming "*delibility*" of black lead! for in the hurry of departure I forgot my card case, therefore I fell back on the most convenient substitute. Let me observe that names written on paper were very generally tendered and received, therefore I wondered on what grounds my name was omitted from the list. I consulted the oracle, who consulted *his* book of fate. Ye gods! therein was recorded the *recognised number of marks to qualify me for my certificateship*, but *two of my papers were written by a black lead pencil!!*—a crime sufficiently grave to disqualify an Alderman, I was given to understand. Stern and unmovable as the Sphinx, not to be twisted nor swayed by any explanation, was Mr. Robert Smith. My name was written in pencil, and that "*clinched*" the matter.

In due time I mentioned the case to Mr. Collis. "What! do you tell me Robert Smith attempted to retain your certificate, and at the same time acknowledges that you attended the proper number of meetings to entitle you to it?" he asked. "Yes, such are the facts," I answered. "Come with me," and he led me from ward to ward until he met with Mr. Wharton and, I think, Mr. Porter. My grievance was *re*lated, a consultation held, and it was determined to see Dr. Stokes—then in the board room—on the subject, who, in a quiet sort of way "would see that I was rightified." Mr. Collis, Mr. Wharton, and myself entered the board room. Mr. Wharton, with that genuine courtesy for which he is distinguished, introduced the subject to Dr. Stokes. Mr. Collis supported the plea. Dr. Stokes rubbed his temples, and declined to interfere. My teachers appeared to be much disappointed, and I retired, grateful to them.

That Pathological session had closed, but Mr. Collis desired that I should remind him of my case, and during the coming session he would see justice done me.

At Dublin death has removed from the midst of the profession a noble soldier in the person of Mr. Collis. Reading the Obituary of him in the MEDICAL PRESS AND CIRCULAR conjured up vividly and distinctly to my mind this little incident. I affectionately place it on his grave, a chaplet to his memory, and *in Perpetuum in memoriam.*

Correspondence.

SUGGESTIONS IN MEDICINE.—No. III.

MR. EDITOR,—Among the variety of symptoms attending consumption, there is none more distressing perhaps than the cough. Often this may be considered salutary, as evidencing the efforts of nature to dislodge something offensive in the air-passages; but, in the later stages, there is a continued short, dry hacking, that greatly annoys the poor sufferer and appears to answer no good purpose. It seems to depend on morbid irritability of the air-passages, and more especially of the epiglottis and adjoining parts of the larynx. Medicine is here, doubtless, of great service to soothe and allay. But, even when this fails to give relief, I have found the greatest benefit arise from freely handling such parts as are comeatable. The epiglottis may be readily reached with the finger of the physician. At first there is great resistance. The coughing is increased and even slight retching induced; but by a steady persistence these drawbacks are overcome, and the parts may be handled with perfect impunity. Nothing, in my experience, allays the irritability, and cough depending on it, better than this. I believe it is now a frequent practice to apply a solution of nitrate of silver to these parts for the same purpose. But I employed the former method many years ago when practising in London, and, subsequently, while Medical Officer to the General Hospital in Tasmania. The poor patients in the wards would entreat me urgently to repeat it, as it gave them the greatest comfort and relief.

It always appeared to me that greater efforts should be made to dislodge the tubercles from the lung when first deposited—that is, in their crude condition, ere they become softened. We know that this has always been considered a grand desideratum with practitioners, who have tried to effect it chiefly by means of absorption, and have failed; iodine, mercury, &c., seeming to have little good influence in such cases. It struck me, therefore, that something that would act upon them chemically might be tried advantageously. Considering that the tubercle is seated quite as much in the small bronchi and air-cells as in the parenchymatous structure, and assured by the experiments of Magendie, if I am not mistaken, that absorption of fluids takes place even more rapidly from the lungs than elsewhere, I thought that if a good solvent could be found that would not be injurious to the delicate vital tissue, it might be possible to employ it even within the thorax. My hopes rested on the acetic acid, which I found to have considerable power over tuberculous matter out of the body. At first I employed it in the form of vapour. Subsequently—that is, about twenty years ago—I got bolder, and proceeded to inject a small quantity of weak acetic acid into the larynx, by means of a small syringe with a knob at the extremity of its curved pipe. The nozzle I found could be directed to the epiglottis by the finger and placed beneath it readily. The fluid was then slowly and cautiously injected. By the symptoms, appearance, and sensations of the patient, I felt certain that this generally trickled down into the lungs. At first but a few drops were used, and these gave rise to such symptoms of dyspnœa as made me feel very anxious and uncomfortable. But, finding these effects soon pass off and the patient none the worse for them, I gradually increased the quantity, so that many times a drachm or more of fluid has been introduced at one sitting, *stillatim*, into the thorax. They were always young subjects on whom I operated, with merely the indications of tubercle. Yet, it must be owned, it requires some nerve to operate in this way on a fresh patient. Those who have submitted two or three times, seem to be but little incommoded, and describe their sensations as similar to those arising from having allowed a portion of fluid while drinking to go the wrong way.

It remains now to state the result of this novel proceeding. My experience of its effects has not been sufficiently extensive to warrant my stating anything very positive, but I regard the effects as very encouraging on the whole. There was a much more free expectoration after the injection, and the dulness on percussion, and other indications of tubercle, were lessened considerably. Indeed, in two or three instances, when the process was several times repeated, the respiratory murmur was to be heard throughout, all want of resonance, &c., ceased, and I considered the patient quite relieved. It would be better, however, I imagine to employ the solvent in the form of vapour, under the circumstances hereafter described, if found safe and equally efficacious. From this system I auger great things.

The next suggestion I have to offer is with respect to those cases of consumption where the disease, although far gone and likely to prove fatal, is entirely confined to one side of the chest—phthisis pulmonalis of one lung only. These cases are rare indeed, but not so much so as might be generally imagined. Tubercle is frequently limited to one lung, and to the upper lobe or lobes of it. No want of resonance, bronchial respiration, or other sign of impeded air action can be detected in the other. *Post-mortem* inspection reveals the accuracy of this research. This isolation of tubercle is, as is well known, the rule at the commencement of phthisis, as it extends afterwards. But occasionally, and, as I have stated, not very unfrequently, the one viscus becomes utterly diseased and destroyed, while the other continues perfectly sound and normal. The one entire lung gets infiltrated, the tubercles soften, and the two or three lobes become studded with vomicæ. Still, as the disease progresses on one side of the thorax the other remains *in statu quo*, or rather increases in vital strength and energy, able to carry on all its functions normally. In some instances, of which pathologists are well aware, the disease runs through its entire course in this way. The viscus is utterly destroyed, shrinks away, and is found years afterwards, when death has arisen from other causes, contracted into a small lump against the dorsal vertebræ, in such manner as to show that it had long ceased to assist in the aëration of the blood, and that this vital process had been alone effected by the surviving organ. Here nature interposed in a manner almost miraculous, as if to show man what could be done. Such lessons, when given in any department, ought to be diligently conned and implicitly followed.

Generally, however, the case is otherwise. Vomicæ form, extend themselves by erosion and absorption into large abscesses, and the patient sinks, not so much as ordinarily from deficient aëration of the blood, for that is effected by the other viscus, but from constitutional irritation and excessive discharge. This disease is hence as fatal and often as rapid in its course as if both lungs had been implicated. Practitioners must have met with such instances in the course of their experience. I am quite aware that I am stating nothing but what is well known. I have come across several cases myself and inspected the bodies after death. The one lung was apparently sound; the other, the cause of disease, riddled with large abscesses, except in the few small points that were so hepatised by inflammation as to be totally unfitted for their special function.

It was from witnessing this havoc that I bethought me—surely something out of the common way should be tried in such exceptional cases. If I had had health and strength I should doubtless, long ere this, have put to the proof of experience the method I now leave to others to adopt if they should think well so to do.

What I propose is, that the diseased lung should be sacrificed —amputated, as it were—in a comparatively early stage, in order to save the life of the patient. Of course this does not mean that the viscus should be excised—cut out of the thorax —for that would be perhaps impossible in the living subject, but that the obscure operation of nature should be imitated, and the lung be made, artificially, to collapse against the spine. I will presently show how this is to be accomplished. After all, it is but applying the same rule of practice to the internal, that is employed so beneficially to the external organs. When a limb is so far injured by an accident or invaded by disease—mortification for instance—as to imperil life, is it not customary to sever it? The part is sacrificed to save the whole. So should it be with the organ under consideration. When the phthisis is strictly confined to one lung, the other being healthy and the disease has not progressed so far as to seriously injure the constitution—when, in fact, circumstances are so far favourable as to hold out a fair promise of success—let the offending member be put *hors de combat*, and rendered incapable of doing further mischief. The lungs are happily double, as if originally designed for such an emergency. At least, so we speculate with respect to other organs of the body—those of special sense, for example. We believe that the Allwise bestowed them in pairs so that the function might still be exercised if one of them should be accidentally injured or destroyed. The case is similar with respect to some of the internal viscera. When double, one of them often becomes spoiled, yet the vital functions are maintained normally by the other. So with respect to the organs under consideration, the lungs. Nature herself, as I have previously stated, occasionally renders one of them totally inert, yet air action and calorifaction are well sustained for years afterwards by the uninjured viscus:

The question now arises—"Can this amputation, so to speak, of the lung really be effected?" I believe it can, without great danger or difficulty. The plan I would suggest is this. In the cases and under the circumstances previously indicated, the patient being seated in a well-warmed room, let a hollow needle, of moderate size and with a valve at the outer extremity, the same being now closed, be inserted between two of the ribs on the side diseased, so as to reach the bag of the pleura. When all agitation has subsided, the valve may be opened and a small portion of warm air admitted into the cavity at each act of inspiration. Then let the stop-cock be turned again. Of course, in accordance with this ingress, there will be a corresponding collapse of the lung, and it is to be hoped, expectoration or ejection in some way of the pus and other noxious fluids contained therein. This elimination should be encouraged as much as possible. After a time, to be determined by the condition of the patient, more air could be admitted, but always in a slow, cautious, and guarded manner, until the lung is completely emptied of its contents and firmly contracted against the dorsal vertebræ.

Here it would be no longer a source of irritation and debility. In this quiet, inactive condition the vomicæ would probably contract and cicatrize; at all events, they would be placed in the most favourable condition to do so. The other lung would maintain the vital functions of aëration and calorifaction.

The simple instrument I have mentioned would, I should judge, answer every purpose. It might be withdrawn and reintroduced, or, if not the source of irritation, held in its place by bands round the thorax. There would be little danger of exciting pleurisy by so fine a puncture, and the smallness of the bore would almost ensure that which is so essential—viz., the very slow and cautious admission of the atmosphere. This ought, as I have previous stated, to be regulated in strict harmony with the strength of the patient and the elimination of the fœtid secretions.

No difficulty will, I imagine, be experienced in penetrating to the pleural sac and no further. It will be remembered, that many years since a somewhat similar process was proposed by certain humane people for slaughtering cattle. Air was to be admitted into both pleuræ, with the intent of inducing death by asphyxia. Here, on the contrary, it is to be hoped that life—human life—which it is clearly the duty of the physician to guard and prolong, will be saved and rendered more healthful and happy.

Other sanatory aids could be employed in conjunction with this process. These relate also, and more especially, to ordinary consumption—phthisis of both lungs—of which I have still to treat. It is, however, of too great importance to be more than alluded to here, so it will form the subject of my next letter.

Your obedient servant,
Bath, *March*, 1869. TOOGOOD DOWNING, M.D.

(To be continued.)

◆

PAUPERISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read this day in your issue of the 17th inst., a report of a discussion on Pauperism and its Causes at a scientific society in London. Will you kindly permit me to say to your readers a few words on this subject; which is now beginning to be a cause of no little apprehension in the minds of intelligent men in England and in Scotland; in which countries one person in every twenty is a pauper—and the number is increasing? The number has risen in Edinburgh to one in ten, and the cost of their relief in that city now amounts to 13s. per head of its whole population. The cost in all Scotland has risen since 1816, when it was 4¾d., to its present rate, which is 5s. per head. These figures I take from a recent pamphlet by the Rev. Professor Kirk, of that city. Drink is the cause of this dangerous state of affairs.

It is no wonder that much anxiety should be evinced there, and, indeed, in wealthy England also, in regard to this matter, where one million of her people are paupers.

The gentlemen who carried on the discussion which you have given to your readers, nearly all seemed to concur in the opinion, that the only way to cure the evil of over-population, and of the destitution they conclude it causes, is, to induce the people of Great Britain to be satisfied with fewer children—for husbands and wives to be each content with two, instead of five or six little ones. In this way they propose to arrest the fearful influx of babies, who are threatening, like locusts, to eat up every green thing, and bring sorrow, instead of joy, on the land.

I have no faith in their remedy, nor in the theory of over-population; we have yet abundance of room for the little ones who come to gladden the hearts of fond parents; and in due time to give their labour in the production of wealth and of all the comforts it brings in its train. This problem, which multitudes, both here and at the other side of the Channel, stumble at, I now proceed to prove by the following reasoning:—

The over-population theory is taken by many as a dogma which cannot be disputed. Let us see. I hold the opinion that no country is over-populated that can produce sufficient food to maintain, in health and vigour all its inhabitants; or whose people can earn money enough to buy sufficient food to supplement their deficiency—if deficiency there be—elsewhere. If this be a true theory—and I apprehend few will be found to dispute it—I have but to show that Great Britain and Ireland are in that position, in order to prove my case. That they are in that position, I think I can clearly prove.

It would take up too much of your space were I to go into a long array of statistics to exhibit their present production of food—animal and vegetable—nor is it necessary I should do so. Taking the whole United Kingdom, it is true that a large annual import of food is necessary to supply the wants of the population, under our present system of agriculture; but the demand which this necessitates on the constantly accumulating capital of the country is not felt. That accumulation is over one hundred and thirty millions a-year.

Notwithstanding this power to supply the wants of a much larger population than this Kingdom now contains, we have doubtless a great deal of poverty in these lands; but that is not owing to over-population, for we certainly could maintain in comfort a much larger number of inhabitants in these countries than they at present contain, if our resources were properly applied; so that the existing distress must be traced to other causes than over-population. I attribute it in part to an universe distribution of the wealth of the nation, which is encouraged, instead of being discouraged, by the laws and customs of our country. Your space will only permit me to illustrate this view by a reference to one striking misapplication of those magnificent resources of our country, which would not alone render unnecessary the existence of anything like misery among us, if they were wisely applied, but would afford abundant and profitable occupation, and that constantly to a far larger population than that now existing; which is deemed—erroneously as I conceive—an incubus that should be relieved by emigration. This does appear to me an erroneous theory. I believe we are yet far from any such necessity, if wiser measures were adopted for the promotion of prosperity and comfort among all the people. The one striking evidence in proof of this opinion, to which I refer, is found in the fact that we expend and waste every year, in the creation of misery, upon poisonous alcoholic liquors, which are in no way conducive to health or strength, one hundred and fifty millions of pounds sterling. Turn this enormous sum into channels that would be productive, and ever reproductive, of still increasing wealth; and no person of sense and reflection can doubt for a moment that the rational means for exterminating our poverty, and of banishing our pauperism, are at hand, and may be applied without doubt of their efficacy, by cutting off this indefeasible expenditure.

There is no necessity for lessening the happiness of domestic life, as hinted at by your learned friends, to secure these great ends; on the contrary, twice the number of our present population would find ample occupation, and good wages to boot; and for many generations to come, every new-born baby would be welcomed as a useful consumer, instead of being considered a burthen in the family; for their future labour would amply repay all expense incurred in their youth.

I could readily elaborate this idea—which I believe to be the true one—and not the over-population theory. If statesmen and landholders place such impediments in the way of agriculturists, as render it all but impossible for them to obtain the largest production which our fertile soil and genial climate would freely yield, that is no good reason why they should start an over-population theory, to hoodwink the people, and shelter themselves under their own misdoings.

I have pointed out one of the many most mischievous and most enormous misdirections of our annual resources. In the interests of public health; of scientific truth; of morality; of order; and of philanthropy; I am justified in imploring—nay, demanding—of our rulers and our people, that our mischievous, our ruinous, drinking customs shall be put an end to; and that our whole population in these lands shall have the means put within their reach, amply to feed, clothe, and house themselves by their own industrious efforts in the land where they were born, and which they enrich by their labour. I would not feed in idleness those who were able to work.

I am, my dear Sir,
Very truly yours,
James Haughton.

35 Eccles street, March 24, 1869.

PROFESSOR HUXLEY'S THEORY OF THE PROTOPLASM, OR PHYSICIAL BASIS OF LIFE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the "Mirror of Science" of the 9th of April, an article appears by Mr. Joseph Wallace of Belfast as an answer to the learned professor; one portion I quote as of vital interest to the medical profession—viz., "Syphilis, cholera, or any other contagious or epidemic disease is unknown in India amongst those who live on vegetarian diet; but induce a young girl to live on fresh meat and alcohol, and thereby increase her animal propensities, &c., &c. Syphilis, then, can be, and has been generated by intemperance of the animal economy, where it was unknown before. She then becomes of course susceptible to the disease of other flesh eaters."—Now sir, this is a bold statement. In my Eastern experience I cannot satisfy myself that a strict vegetarian is free from venereal disease. On what ground does he assert that vegetarians are never attacked by cholera, contagious or epidemic diseases? Will Mr. Wallace give facts, if so, he can enlighten the medical profession as to these great scourges of humanity.

A Physician.

NITROUS OXIDE IN DENTAL SURGERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—We must all feel much indebted to Mr. W. S. Whatford for bringing under the notice of the profession the notes of his two interesting cases which appeared in your number of March 31. To help us to explain these phenomena we must bear in mind two facts which often come under our notice. In the first place, when people have taken a few inspirations of the gas they usually feel a numbness and tingling in the fingers, and in a few cases this numbness remains for a longer or shorter time after the patient has recovered consciousness. This numbness varies much in degree: it may be just perceptible, or it may be severe, as in the three cases following. In one case, that of a lady aged about thirty-five, the patient declared herself unable to move her hands for about half a minute, and during all the time she was regaining full consciousness she continued exclaiming, "Oh! I have lost the use of my hands!"

A girl of eighteen, to whom the gas was administered, complained of numbness and loss of power over the fingers for as much as half-an-hour after recovery.

A pupil at the Dental Hospital complained of, long before consciousness was lost, a most distressing feeling in both hands, and begged his fellow students standing around him to rub them hard.

In the second place, we know how, after an amputation of the arm or thigh, the patient complains of disagreeable sensations in the fingers or the toes, as the case may be; that is, he refers the sensations to the sentient extremities of the irritated nerves; and as these have always been in the digital extremities, to those parts does he refer his disagreeable sensations.

Remembering these facts, I think we can now well understand why the sensation appeared to the patient to be in the fingers of the amputated extremity. In the soldier's case, Mr. Whatford does not say the right hand was unaffected; and in the matron's case, from her saying "she felt much more pain in the left arm," I infer she had some in the right arm and hand also. I cannot, except in two cases, say that I have met with any of the alarming symptoms Mr. Whatford speaks of. As regards the dreadful dreams, I think the prevailing idea in the patient's mind as unconsciousness sets in gives the tone and colour to the dream which follows; and therefore it is always well to gently reassure the patient and use any means you can to overcome the nervousness which so often exists. I have found one great source of disagreeable dreams to be the unequal pressure of the gasometer, the gas, either being forced into the patient's mouth from the counterpoise being too light, or, what is more disagreeable still, a difficulty in inhaling from the counterpoise being too heavy; in both of these cases the patient often dreams of strangling, or drowning, or some subject connected with difficult respiration.

Perhaps Mr. Whatford will kindly mention in what way the patient is suffering who has been ill for two weeks? My own experience of nitrous oxide is most favourable. I confess I should be sorry to have a tooth removed with being previously put under its influence. I do not say that there is not a certain amount of risk with the gas; but as compared with the risk of chloroform, it is exactly one half, for chloroform may prove fatal by paralyzing the heart's action, or by causing cessation of breathing: and in all the animals I have seen killed by this agent the heart's action continued after the respiration had ceased. Apologising for the length,

I am yours, &c.,
A. F. Brain, F.R.C.S.

Medico-Parliamentary Intelligence.

HOUSE OF COMMONS.

April 5th.

DIRECTOR-GENERAL OF THE NAVY MEDICAL DEPARTMENT.

On the vote of £54,757 for the expenses of the medical establishments at home and abroad.

Mr. Corry said he could not allow this vote to pass without congratulating the First Lord on the discrimination he had shown in appointing Inspector-General Armstrong to be Director-General of the Medical Department of the Navy. He felt bound on public grounds to say he believed that this appointment would be conducive to the best interests of the Navy.

Mr. Childers said he had taken three months to make this appointment. It was too important to be made in a hurry. He was glad to hear the testimony borne by the right hon. gentleman to Dr. Armstrong's claims.

The vote was agreed to.

◆

Medical News.

The usual Monthly Meeting of the Metropolitan Association of Medical Officers of Health will be held on Saturday, the 17th inst., at 7.30 p.m., at the Scottish Corporation Hall, Crane court, Fleet street, when a paper will be read by Dr. Letheby, "On the methods of estimating nitrogenous matters in potable waters; and on the value of the expression 'previous sewage contamination,' as used by the Registrar-General in his monthly Reports of the Metropolitan Waters."

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

To the names of gentlemen mentioned in another part of our issue as likely to compete for the vacancy in the Council caused by the death of Dr. Mackesy, we have to add those of Sir William Wilde, oculist to Her Majesty in Ireland; Mr. Smyly, surgeon to the Meath Hospital; Dr. Barton, surgeon to the Adelaide Hospital; and Dr. Quinan, secretary to the Irish Medical Association.

◆

Obituary.

DEATH OF DR. MACKESY, OF WATERFORD.

It is our melancholy duty to record this week the death of another eminent member of our profession. Dr. Mackesy, of Waterford, had reached the ripe age of seventy-eight, and had been just sixty years in practice at the period of his death. His career was no ordinary one. He became a Member of the Royal College of Surgeons of England in 1809, and some time afterwards settled in Waterford, where for many years he has practised with great success, and we find his name intimately connected with every charitable institution in that locality. His reputation, however, was not limited to Waterford. He was appointed a Member of the Council of the College of Surgeons, and in 1862 was elected President of the Royal College of Surgeons in Ireland, being the first provincial surgeon who ever obtained that high honour. As President of the Irish Medical Association, his sage advice and kindly feeling has always endeared him to his professional brethren, and there, more especially, will his loss be felt. Within the last few months death has been making sad havoc in our ranks, and no one more universally beloved or more deeply regretted than Dr. Mackesy, of Waterford.

NOTICES TO CORRESPONDENTS.

SPECIAL NOTICE TO SUBSCRIBERS IN IRELAND.

The Subscribers are respectfully informed that the offices of this Journal have been removed to Moflat and Company, 6 D'Olier street, Dublin, to whom all business letters should henceforth be addressed. Editorial communications should be sent to Dr. Jacob, 23 Ely place.

Evan Evans, Dorking, Surrey.—As your name does not appear upon the "Official Register" or in the "Medical Directory," we could not for an instant entertain the idea of advertising you as M.D., &c. Your liberal offer is, therefore, respectfully declined. Moreover, your "Announcements" are not likely to "be favourably received" by the readers of this Journal, and we would advise you to send to other *media*, as there are plenty of publications open to such advertisements.

James Jefferson, Esq., Forest Hill.—Probably the same individual as the foregoing. In any case, this person is referred to the previous notice.

Oculist.—The statements of our contemporary respecting the history of the Ophthalmic Hospital were entirely erroneous.

Registered.—The protection of the unqualified person by a registered one is worth being brought under the notice of the Medical Council.

On Cancer of the Rectum. By Mr. Holmes Coote, F.R.C.S., received.

Carbolic Acid in the Treatment of Buboes and Skin Sinuses. By J. Lamprey, M.B., Portsmouth, received.

Sir Duncan Gibb, Bart., will please receive our best thanks for the kind suggestion contained in his note.

Mr. Jameson. the alterations have been attended to.

Dr. Ewing Whittle, Liverpool, and Mr. Falconer Clark, are thanked.

SYPHILIS IN PREGNANCY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—In your report of the meeting of the Medical Society of London in your last issue you state that Dr. Dunn, in his reply, said "that secondary syphilis showed itself in the second and third months, and not in the first."

The statement I made was that, from my own experience and facts I had collected on the point was that hereditary syphilis first appeared most frequently in *the second and third months* of an infant's life, not in the first month, as Mr. Hamilton stated.

I trust, therefore, you will kindly correct the statement your reporter has made.

I am,
Yours, &c.,
R. William Dunn.

Surrey street, Strand.

APPOINTMENTS.

Bennett, C. J., M.R.C.S.E., has been appointed Surgeon to the General Hospital and Dispensary, Cheltenham, vice W. Philson, M.D., resigned.

Burder, G. F., M.D., has been re-elected Physician to the General Hospital, Bristol.

Cumming, J., M.B., C.M., has been appointed Assistant Extra-Physician to the Royal Sick Children's Hospital, Edinburgh.

Finch, Dr. J. E. M., of the Leicestershire Lunatic Asylum, has been elected Resident Medical Superintendent of the new Leicester Borough Lunatic Asylum.

Galton, J. C., M.A., F.L.S., M.R.C.S., has been appointed Lecturer on Comparative Anatomy at Charing-cross Hospital.

Langmore, J. W., M.B., has been appointed Physicians' Assistant at the Middlesex Hospital, vice W. Maine, M.R.C.S.E.

Lough, J. J., M.B., has been appointed House-Surgeon to the Liverpool Infirmary for Children.

Phillips, J. J., M.D., has been appointed Assistant-Physician to the Hospital for Sick Children.

Pierce, F., M.D., late Resident Medical Officer to the Brixton Dispensary, has been appointed House-Surgeon and Secretary to the Victoria Hospital for Sick Children.

Ross, G., M.D., has been appointed Medical Officer of Health for the Parishes of St. Giles and St. George, Bloomsbury, vice G. Buchanan M.D., resigned.

Rouch, J. R., L.R.C.P.L., has been appointed House-Surgeon to the Bradford Infirmary and Dispensary, Yorkshire, vice H. T. Broughton, M.R.C.S.E., resigned.

White, Dr. J., Medical Officer of Dispensary, &c., has been appointed Medical Attendant to the Constabulary Force of Rickhill Station Co. Armagh.

Wolfe, B. J., M.D., Surgeon to the Ophthalmic Institution, Bath street, Glasgow, has been appointed Lecturer for the recently appointed Chair of Ophthalmic Medicine and Surgery at Anderson's University, Glasgow.

Woods, G. A., L.R.C.P., M.R.C.S.E., has been appointed Honorary Surgeon to the Southport Convalescent Hospital.

◆

VACANCIES.

The Leeds General Infirmary.—Four Assistant Resident Medical Officers. To take the charge of wards in new building. Apartments, board, &c., found. Election, April 17th. See advertisement.

The Chair of Botany at the Charing cross Hospital Medical School.

Poplar Union.—Medical Officer. Salary, £100, exclusive of fees.

Royal Albert Hospital, Devonport.—Assistant House-Surgeon. Salary, £50, with board and residence.

Victoria Hospital for Sick Children, Chelsea.—Assistant-Surgeon.

◆

DEATHS.

Blades.—On the 26th ult., at Blackburn, W. D. Blades, F.R.C.S., aged 54.

Cox.—On the 6th of Feb., at Valparaiso, Nathaniel M. Cox, Surgeon, aged 85.

Gale.—On the 3rd inst., Richard, the infant son of Dr. Gale, of Poplar.

Hall.—On the 30th ult., at Southsea, J. Hall, M.D., Surgeon, R.N., aged 84.

Harness.—On the 30th ult., H. S. Harness, Surgeon, of Fulham road, aged 70.

Loe.—On the 24th ult., Gertrude Eliza, fifth daughter of J. S. Loe, M.R.C.S.E., in her fifth year.

Miles.—On the 23rd ult., H. Miles, L.S.A.L., of Gillingham, Dorsetshire, aged 71.

Morgan.—On the 7th inst., at Penffordd House, Newport, Monmouthshire, Ann Aitken, the beloved wife of W. W. Morgan, M.D., J.P.

Pearce.—On the 5th inst., J. W. Pearce, M.R.C.S.E., of Peterborough.

A SUGGESTION FOR THE SANITARY IMPROVEMENT OF TOWNS AND DWELLINGS.

By Zachariah Johnson, A.M., T.C.D., F.R.C.S.,
Licentiate of the Royal College of Physicians, Dublin; Surgeon, Kilkenny Co. Infirmary.

SANITARY Science is a subject of such acknowledged importance that it scarcely seems necessary to offer an apology for any observation or suggestion, however humble, which may tend at once to point out a defect in the arrangements which modern civilization has adopted in the furtherance of sanitary security, and to indicate an easy and effective means of obviating that defect.

It will be conceded on all hands that a vitiated and impure atmosphere exercises a pernicious effect on the health of all members of the human family living within the precincts of its influence. The comparatively unhealthy and prematurely aged aspect of the citizen, contrasted with the robust and hale appearance of the peasant of equal age is a familiar fact. That this is owing to the effects of the more impure atmosphere, in which the denizen of the city spends his life, would appear to be established by the consideration that while the citizen usually enjoys the advantage of a better dietary, the peasant, even when dependent on the poorest and most inadequate diet, far exceeds him in vigour and healthiness of aspect, the purity of the atmosphere which the latter breathes proving manifestly more than an equivalent for good diet with bad air.

Among the means which civilization has introduced for the purpose of purifying the atmosphere of our towns and dwellings, none is more familiar or important than the sewer. Its object plainly is to carry out of sight offensive matter, and to confine and imprison gases resulting from decomposition, which not only offend the senses, but which were long since observed to be deleterious to health. The inhabitants of crowded districts, where the sewerage is insufficient, or ill-contrived, and where the atmosphere is deeply impregnated with the gases extricated by the decomposition of organised matter, too plainly bespeak, by their wan and cachectic appearance, the deadly influence of some pernicious agent; and on the outbreak of any epidemic, whether cholera or typhus, small-pox or scarlatina, erysipelas, or malignant exanthem of any class, it is but too notorious, not only how much the spread of the disease has been promoted, but how much its malignity has been increased, by the presence of bad sewerage; for, although it cannot be pretended that the gases of decomposition constitute the essence of zymotic or epidemic disease, it cannot be denied by any practical observer that they assist and contribute, in some inexplicable manner, to the spread and propagation of such diseases, while, under ordinary circumstances, they exercise a deteriorating influence on the health of those subjected to their effects.

The deficiency of the covered sewer, and the inconvenience and danger arising from the escape of the sewer gases, which had become only more concentrated and more powerful by their accumulation and temporary imprisonment, soon became apparent, and the expedient of trapping the apertures of the sewer, both where they open in the street channels and also in the sculleries and areas of private dwellings, was adopted as a preventive of the bad consequences following on the escape of sewer-gas.

The fact seems to have been overlooked that in merely trapping the higher apertures of the sewers, the dangers resulting from the imprisonment of the sewer gases were positively increased, and that, in order that the trapping might fulfil the intention with which it was adopted, another, and further precaution was necessary, which has been almost altogether neglected, and most of all so, where the danger appears to be greatest and most urgent.

I was led to this conclusion by the consideration of two facts. The great object in all sewers is to have a fall, and consequently the inclination of the sewer, more or less, is downwards, towards its mouth. But the tendency of the sewer-gas, in consequence of its volatility, is *to ascend;* and hence follow most important results.

If the sewers be not trapped, the gases escape from the highest apertures, intended for the admission of surface drainage, or domestic offal. The passer-by is, perhaps, offended by the unsavory emanation, or, in time of pestilence or epidemic, peradventure the noxious effluvia acts the part of ally to the prevalent disease, and he sickens ere he arrives at his dwelling; while, of that gas which makes its escape in the untrapped area or scullery of the private dwelling, a part probably finds its way into the lower regions of the house, to rise from thence to the upper storeys, while a part becomes diffused in the surrounding atmosphere.

Let us now consider the results which follow, when the sewers are trapped, according to the present system, which makes no provision for the ascent of the sewer-gases, their cumulative tendency, their volatility and diffusibility, or the inevitable consequences of any pressure or obstruction occurring at the orifice of exit from the main sewer.

It is now an established fact that the sewer-gases ascend in currents, opposite in their direction to the flow of the contained water and denser materials, which gravitate towards the sewer's mouth. This might naturally be expected, but it has been positively ascertained by a series of experiments undertaken by Mr. Bazalgette, Engineer to the Corporation of London, who, by their desire, instituted these experiments for the purpose of deciding this point, and found the currents of the sewer-gases directly opposite to that of the descending fluids.*

This being the case, and the street gratings being trapped, the gases necessarily find their way from the street mains into the branches leading to private houses, and escape into the area or scullery, if untrapped; but if they are trapped, no resource remains but to ascend the down-pipes of the water-closets, which are too often in the body of the house, and here they are temporarily arrested.

It is not difficult to show that the arrest here is only temporary. The gases being cumulative, and their tendency being to ascend as they increase in quantity, the pressure on the gas, which has attained the highest point, must increase. In the water-closet, the escape upwards of the sewer-gas is prevented only by the water in the trap.† But, water being capable of absorbing gases to some extent, a slow, insensible process is constantly going on, by which the gas, absorbed by the water in the trap, is given off within the closet, and, mixing with the atmosphere of that chamber, must not only vitiate it, but become diffused, more or less, through the atmosphere of the dwelling.

It is to this circumstance, conjoined with the impossibility of making any plumber's work so staunch as to completely prevent the escape of these volatile and attenuated agents (which we know will permeate crevices that water could not pass through) that we are to attribute the heavy, mawkish, oppressive smell which is to be met with in the best constructed and most approved water-closets of the day.

In the case of our street-sewers a somewhat similar process must occur—pressure from like causes must take place upon the roofs and sides of the sewer, and the gases escape through cracks and rat-holes with which all sewers abound. They first become diffused through the superincumbent clay, and, rising to the surface, soon meet the lower strata of the air, from whence it is not difficult to foresee their easy transfer to the lungs of the passer-by.

Thus, the atmosphere of our streets becomes vitiated by the leakage of the gases from the mains, while that within our houses is poisoned by the escape from the house sewers, *the soil-pipe of the water-closet in particular.* It is a mistake to suppose that these mephitic gases find their exit at the mouth of the main sewer, far away from our houses. It is an ascertained and established fact, as already mentioned, that they rise in the sewers, in a direction contrary to the current of the fluid contents, finding their way to the highest levels, from whence they must find vent somewhere, and can escape only in the manner already indicated.

These conclusions were more particularly forced upon me by the observation of phenomena of frequent occurrence in the town where I reside. The houses in one of the best streets, which stand on an incline, at a considerable elevation above the river, and at a considerable distance from it, are liable to become very remarkably foul and oppressive during the prevalence of high winds, which might naturally be expected to ventilate and purify the atmosphere. The circumstance appeared unaccountable until it was observed that the inconvenience, which always bears direct proportion to the force of the storm, is produced only by such winds as bear more or less directly on the mouth of the main sewer. The mystery was now solved, and a clear explanation of the circumstances afforded. The pressure exercised by the wind driving up the sewer plainly forced the gases into the houses.

The inferences to be derived from this observation received further confirmation from a circumstance which occurred in one of the houses in question. The proprietor was greatly annoyed by the escape of foul gas from an open grating placed adjacent to the jam of the back-door; but no sooner had he taken the precaution of having this grating trapped than the atmosphere within the house became palpably more impure than ever, and this was the more apparent in proportion as the wind blew more or less forcibly on the mouth of the main sewer, which empties itself into the River Nore, far away from the house which was thus affected. (In this case the house-sewers pass under and across the house to reach the street main sewer.)

The significance of this fact seems to admit of no doubt, or controversy, and it can scarcely be questioned that the same phenomena are constantly going on in every town in which the covered sewers are constructed on the present plan, the only difference being merely one of degree.

The remedy for an evil which comes home to every one who frequents a town, whether he be a resident or not, seems to be to provide *a free escape* for the sewer gases into regions where they cannot be any longer injurious to man; and this would seem to resolve itself into—firstly, PUBLIC PRECAUTIONS for the relief of the street mains; and, secondly, PRIVATE PRECAUTIONS for the relief of domestic sewerage.

On the first of these I had, some time since, prepared some observations for the Press (being under the impression that my conclusions and proposed remedies were *original*), when I found that the phenomena to which I have referred had been already recognised, and that the necessity for providing safe vents for the imprisoned sewer-gases, had been strongly urged on the London Corporation by so high an authority as Mr. Bazalgette, their able and eminent engineer. The disappointment which may be conceived to arise from ascertaining that a supposed invention or discovery has been anticipated, was here more than compensated for by finding that views which were perfectly original, as regarded myself, were endorsed by the recommendations of so eminent and practical an engineer as Mr. Bazalgette.

---

* For an account of the experiments instituted by Mr. Bazalgette, in order to determine this point, the reader is referred to his Report on the subject, made to the Corporation of London, by their desire, and which has been printed, and can be had through any bookseller.

† It may be necessary to explain that there are two forms of trap in use in water-closets, but the argument applies equally to each. They are called respectively the D trap and the S trap. The latter, or S trap, is the most approved, and that now most in use. The principle in each is the same. The foul gases from the soil-pipe are arrested in their course upward by water, so disposed that the gas must *descend* through this water in order to reach the apartment on the other side of the trap. This it cannot do immediately (in the way we see air, or the lighter gases ascend in bubbles through water, oil, and other fluids); but it does so slowly, by absorption and subsequent gradual evolution. The peculiar mawkish and oppressive effluvia perceptible in the best trapped and most perfect water-closets must be familiar to every one, and is, in itself, sufficient proof of this.

It appears from his Report* that he urged on the London Corporation the necessity of attaching vertical pipes to lofty buildings, and connecting these with the crown of the adjacent street sewer. In some instances he succeeded in prevailing on private parties to allow the *rain spouts* to be placed in connection with the street sewer, care being taken always that the superior aperture was kept as much as possible above the level of the upper windows of the houses. But prejudice, or the fear of permitting this connection to be made, was so great, that in few instances only could he effect it; and there would seem to be little prospect of having this precaution carried out on a sufficiently extensive scale unless taken into hands, as a public measure, by the authorities.

With reference to the relieving of the main sewers, two plans had suggested themselves to my mind as feasible:—

First.—Ornamental columns, such as we now see erected to commemorate human slaughter, with its concomitants of untold misery and bereavement, might be constructed, at the public expense, for the far different purpose of abating human mortality and contributing to health and comfort. Such columns, placed in suitable positions, might be, at once, useful and ornamental; and while they could be made to serve as ventilating shafts for the main sewers, might be utilised at the same time for purposes of public lighting, the telegraph, and other uses.

Secondly.—The lightning conductors of *existing columns* and *church spires*, which are at present formed of *solid material*, might be converted into *hollow tubes* of conducting metal, which would continue to serve the purpose of lightning conductors still, but which, by being brought into connexion with the neighbouring main sewer, might be made to answer the further purpose of carrying the poisonous gases of our sewers into atmospheric strata, far above the dwellings of man, there to be so diluted and dissipated as to be no longer a source of danger or disease.†

These are measures to be carried out only by municipal bodies, unless indeed enlightened Imperial wisdom should yet see the necessity for direct and stringent interference. As it is, our authorities, imperial and municipal, are so blind or so apathetic in all matters relating to sanitary precaution or improvement, that there seems little chance of any such measures, as those suggested, being carried out during the days of the present generation, even though advocated by the highest authority, and though substantiated by the most unanswerable experiments and proofs.

As to the *private precautions*, here there seems more room for hope; and I shall proceed to describe a domestic precaution which, I am persuaded, is of considerable importance, and which is not the less valuable because it is within the reach of every private individual, is inexpensive, easy of application, and would prove, to a large extent at least, effectual in purifying the atmosphere of private dwellings.

I must now recal attention to the fact that where the area and scullery sewers are trapped, the sewer gases must necessarily find their way (subject to more or less pressure from below) up to the soil-pipe of the water-closet, where, so soon as it reaches the summit, it meets the water in the trap, which is intended to arrest its further progress. Partly, however, from the absorbent power of the water, which slowly imbibes the mephitic gases and delivers them from the surface adjacent to the pan, and partly from the imperfections which time and canker will produce in the best of plumbers' work, these gases are slowly evolved, first beneath the seat of the water-closet, where it is natural to suppose they are not detained very long, but from whence escaping (owing to their diffusibility and volatile disposition) they mix readily with the atmosphere of the closet itself, and thence find access to the body of the house.

The remedy which appears calculated to obviate this effectually is, to insert a small pipe into the summit of the soil-pipe, at its junction with the trap of the water-closet, and to conduct this pipe above the roof of the house, where, by attaching it to a chimney or gable, it might easily be reared to a height sufficient to insure immunity from the effects of the disengaged gases.

A piece of ordinary gas-pipe, an inch or three-quarters of an inch in diameter, would be amply sufficient for the purpose, and by its constant discharge of the volatile and ascending gases, would rid our house sewers of what now constitutes a source of danger; and by relieving the pressure at present caused by continually increasing volume, would obviate the leakage which takes place into our dwellings, and, still further, would greatly help to relieve the tension of the main sewers also.

The summit of the soil-pipe is proposed as the point of junction for the vent-pipe, because where there is a water-closet, it is usually the highest point of the sewerage; but where there is not an *elevated* water-closet the highest point of the sewerage should be selected for the insertion of the vent-pipe.

It would seem probable that a more general adoption of the patent earth-closets (which appear to have many advantages, and have been favourably reported on by those who have tested them) will supersede to a considerable extent the present water-closet. But it should be remembered that the water-closet is not the sole means by which foul gases find their way into our homes. Leakage takes place from the best constructed sewers, which is increased by the internal pressure caused by accumulation, where the sewer is trapped; so that, whether it be trapped or not, the pernicious gases are likely to find their way into the house, unless carried into the higher regions of the air. The safest plan, then, would seem to be to trap the sewers effectually, by all means, but on no account to neglect providing a safe means of escape for the sewer gases, which can be done by inserting a vent-pipe into the highest point of the sewerage, whether that be the soil-pipe of a water-closet or not,—only taking care to conduct the vent-pipe to such a height as shall secure immunity from the deleterious nature of its contents.

I fear now that many who expected some profound discovery in physics, or some addition to the inexhaustible resources of chemistry, will have been disappointed. It may be said, perhaps with truth, that the subject was suited, not for a learned society of physicians, but for a company of domestic engineers or a sanitary commission. As I do not happen to belong to either of these bodies I could have no opportunity of laying my views before them, and I do not know any body more capable of judging of the merits of this question than the College of Physicians, to which I have the honour to belong. Besides, if the suggestions I have offered have any real merit, or are calculated to lead to any beneficial result, none can show a claim to their first fruits prior to that of a noble profession, the members of which devote their time and best energies to the alleviation of human suffering, and have never hesitated to risk their lives at the shrine of duty when the interest of afflicted humanity, or those of philanthropic science, required the sacrifice.

---

* The Report already alluded to, and which can be had through any bookseller.

† It has been objected that there might be a difficulty in getting the gases to ascend through these pipes. This objection is, I think, futile. Every house mason is well aware of the necessity for keeping the aperture of any pipe, which communicates with a sewer, above the level of the upper windows, as otherwise the sewer gases would be conducted into the house. *This is a familiar fact.* But even were it not so, it would not be difficult to exhaust the vent-pipes and the sewers themselves by a self-acting apparatus. It is scarcely necessary to suggest the application of a revolving fan, or spiral flange, to the upper end of the vent-pipe, which should be adapted for its reception. The mere action of the wind on either of these would pump up the gases from the sewers. Nor is this all. The storm, which now, by pressing on the sewer mouth, forces back the gases into our dwellings, would then, by its simultaneous action on the fan, effect a thorough ventilation of the sewer. The efforts of nature to purify our atmosphere would be supplemented, instead of being, as now, frustrated; since it is a fact that the storm, intended to purify the adulterated atmosphere, is made, by our imperfect arrangements, to intensify the noxious emanations which it drives now into our dwellings; while the proposed measure presents a means of co-operation with the beneficent design obviously intended by Providence for our benefit, but stupidly perverted by ourselves.

NOTES OF A VISIT TO SOME OF THE SKIN HOSPITALS.

By H. S. Purdon, M.D.,

Physician Belfast Dispensary for Skin Diseases.

During the Autumn of last year I visited the Glasgow Dispensary for Skin Diseases. Dr. M'Call Anderson, my former teacher, showed me several cases of *psoriasis*, which were improving under the use of coal tar, in doses of two drops thrice daily, after food, due attention being paid to the state of the bowels. The internal use of tar sometimes gives rise to dyspepsia, when it has to be discontinued. No local treatment was adopted in these cases, as the effect of the tar could be better observed. An interesting case of "*pityriasis rubra*" was under treatment, and improving under the use of Fowler's solution, and cod-liver oil. Dr. Anderson has recently described, under the name "lupus verrucosus," an affection of the skin called by Hardy, of St. Louis, "scrofuloderma verrucosum." The disease shows itself by warty looking patches, with slight ulceration, from which hypertrophied papillæ stand prominently forth. It is a troublesome affection to cure. Iodized glycerine is the preparation most relied on, and any flaw in the health of the patient attended to. A very good specimen is preserved in the Dispensary, as also specimens of favus in a cat and mouse.

On Friday, March 5th, 1869, I visited St. John's Hospital for Skin Diseases, London. Mr. Milton showed me some cases of lupus, to which he had applied the acid nitrate of mercury with the best results. The patients also had cod-liver oil. When it is necessary to order arsenic in any cutaneous disease, the preparation employed is the solution of the chloride, which very seldom occasions any derangement of the stomach, and is the preparation now used by the majority of dermatologists. I saw several cases of psoriasis, the local application ordered being carbolic acid, five grains to the ounce of water, gradually increased, if the patient can bear it, to ten or even twenty. This remedy rapidly removes the disease when combined with arsenic internally. He had an interesting case of lichen of the face in a little girl, aged twelve years. In this disease Mr. Milton places great reliance in salines, especially in purgative doses, the hospital mixture containing sulphate of magnesia, heavy calcined magnesia, and peppermint water. An interesting case of sycosis of the beard and whiskers was under treatment (but I should have called it a form of impetigo pilaris, as I hold sycosis to be a purely parasitic affection, accompanied in an advanced stage by tubercular elevations, which complaint is extremely rare in this country, as I have had only some three or four cases out of nearly 4,000 dispensary patients). The disease in question shows itself in a growth of small tubercles, which slowly suppurate; at first of the same colour as the skin, a hair running through each, and often leave little pits behind. To use Mr. Milton's own words, it is a "true creeping lupus on a site covered by hair." Many cases of the various varieties of eczema presented themselves. Debility is looked on as the essential cause of this affection, and, no doubt, in large cities it usually is. The iron mixture of the hospital is generally prescribed; it consists of a simple solution of iron in strong muriatic acid. Locally, benzonated zinc ointment is applied, the patient being desired to wash in very hot water. Mr. Milton, after a fair trial, informes me that he has lost all faith in Hebra's black soap and potash treatment. Scrofulous affections of the skin are not so common as formerly, although on the increase in country districts. This Mr. Milton attributes to the improved sanitary condition of the city, and also to the better food used by the lower classes. In chloasma, which he believes is seldom, if at all parasitic, he puts most faith in sulphur, fumigations, and chloride of arsenic internally. Sometimes strong tincture of iodine painted on the affected part removes the disease quickly. Any cutaneous disease accompanied by the formation of crusts, which have to be removed, he anoints with oil or lard, and subsequently stupes with either warm water or linseed tea. Poultices he avoids as much as possible, as they weaken the "tone" of the skin, and give rise to boils. I was able to see a case of tubercular leprosy, the diagnosis of which Mr. Milton informed me had been confirmed by Mr. Erasmus Wilson. The patient was between thirty and forty years of age, and had resided for many years in the East Indies, where he was first attacked by the present disease. Words cannot convey an accurate account of the appearance of the skin. I may, however, state that there was ulceration of the fingers, ali-nasi palate and fauces, with insensibility to touch in the arm and legs, as also to heat and cold. The conjunctivæ were slightly bloodshot, and sense of smell gone. The affected skin of the face and arms was characterised by patches of a purplish colour, and elevated tumours of irregular size and shape, some of which were running into ulceration; the hair of the whiskers had fallen out. The patient had taken arsenic, also hydrocotyle asiatica, but without benefit. In acne, Mr. Milton exclusively uses the hypochloride of sulphur ointment applied every night, and generally gives nitric acid and infusion of quassia internally; subsequently, if necessary, arsenic. An interesting case of urticaria subcutanea of the legs occurred in an elderly female, and which might have at first been mistaken for erythema nodosum. In this case he prescribed colchicum and magnesia, and informed me it seldom fails. In a case of chronic infiltrated eczema of the hands and fingers, the patient was getting well under the influence of the bichloride of mercury. In such cases as this Mr. Milton makes the patients constantly wear gloves, and he called my attention to the fact that butchers or others who work amongst greasy substances never have this disease. When wine is required, he orders "Taragona."

At the Hospital for Skin Diseases, New Bridge street, Blackfriars, which numbers amongst its surgeons, Startin, Hutchinson, and Nayler, I had on Thursday, March 4th, 1869, an opportunity of witnessing the practice of Mr. Sims, the assistant surgeon. I suppose that at least 200 out-patients were prescribed for. I was much struck with the frequency of alopecia areata, a rare disease here; at least six cases presented themselves, and Mr. Sims informed me that it is rather common. He holds it to be essentially parasitic. The treatment adopted is to blister the affected part with glacial acetum cantharidis, and to improve the health with cod-liver oil or nitric acid. Several cases of psoriasis occurred in young females, who were anæmic looking, for which affection the red ointment of the hospital was prescribed, which contains red precipitate of mercury. The iron mixture, with or without aloes, was also ordered. In syphilitic psoriasis, of which disease a good example presented itself; the iodide of potassium and mercury mixture of the hospital was prescribed. Many cases of acne presented themselves, which disease is often accompanied by a disordered state of the digestive organs, and foul tongue. In these cases the medicine generally given at first is the magnesia and colchicum mixture, subsequently arsenic; creasote ointment being a common stimulating local application. In all cases soap is forbidden; bran-water gruel, or linseed tea being used instead, to the affected part. Printed rules of diet are given to each patient. In phtheiriasis, the compound sulphur ointment of the hospital pharmacopœia is used, which contains besides sulphur, various essential oils. This hospital has a large suite of baths. In squamous affections, glycerine or starch baths are sometimes used, or alkaline, but there is this noteable distinction between the British and French modes of treatment, that in the former, internal remedies are more relied on, whilst in the latter, local treatment is principally adopted; but, of course, cutaneous diseases vary according to the country in which they occur.

At the Liverpool Hospital for Skin Diseases, Mr. Smyth uses a preparation of his own in various squamous diseases, viz., tincture of sulphur. He also prescribes phosphate of zinc in diseases accompanied by much debility. His favourite preparation of arsenic is the solution of the chloride. In lupus he uses the acid nitrate of mercury, and epilates in sycosis. Ulcers are treated with carbolic acid ointment. In the class of diseases called scrofuloderma, he gives tincture of iodine internally. Mr. Smyth has invented a chloroform inhaler, which I now show to the society.

FOUNDATIONS OF THE SCIENCE OF HYGIENE.

By a London Physician.

The Medical Press and Circular recently called attention to the fact that the teaching of hygiene in our medical schools is now beginning to be felt as a necessity of our times. The appearance, too, of several works on this important topic from the pens of Drs. Parkes, Mapother, and other eminent physicians, testifies to the conclusion that this branch of preventive and curative medicine is soon destined to engage much attention. The most important of all questions in the domain of hygiene, however, turns out to be that of wealth. Thus Villermé, Quetelet of Brussels, Casper of Berlin, &c, have long ago conclusively shown, what indeed I might expect, that, in addition to the numerous other advantages arising from the possession of wealth, there must be placed to its account the greater longevity attained by members of the richer classes, in comparison with the poor, and even with the less wealthy of the middle classes. The summing-up of this truth has been admirably made by the learned and most distinguished professor of logic of Aberdeen, Mr. Alexander Bain, in an appendix "on happiness," in his recent work *On Mental and Moral Science*, in the following words :—"The prime requisite of happiness, health, is very imperfectly secured in the lowest grades of respectable citizenship. The public registers have demonstrated that mortality and disease diminish at every rise in the scale of wealth." The worst chance of life and health, as I should naturally have expected, turns out to reside among the poorest classes. To remove pauperism, then, and indigence would at once be a work of benevolence and hygiene. How impossible poverty renders it for the poor workman to take the necessary care of his or her health, those of us who have much hospital experience see every day. Consumption is well known to be very much more frequent among the ill-fed classes, both from their bad living and bad rebreathed air, as Dr. M'Cormac has it, and fever and zymotic diseases, including venereal complaints, are, as all know, far more prevalent wherever bad ventilation and over-crowding in cheap lodgings exist.

Readers will, for the most part, be ready enough to concede the point, that indigence and bad living are the greatest of all foes to the attainment of health and longevity. Some admirable attempts have recently been made to grapple with the question of pauperism and the evils resulting from this gigantic evil of our modern societies. Dr. Stallard and Dr. Hardwicke, and others, have a considerable faith in the power of a different administration of our Poor-law system to produce a diminution and almost a disappearance of able-bodied pauperism. If I understand the views of Dr. Stallard aright, as put forward by him in a pamphlet recently published, that gentleman believes that it would be possible to employ *productively* all able-bodied applicants for work, who, in exchange for a clean bed and a frugal meal, might be forced, he says, to do enough productive labour to pay for these parish gifts. Some other gentlemen, who seem to think that such a scheme as that proposed by Dr. Stallard would be inadequate, and who appear to believe that we are over-peopled, suggest large schemes of government emigration. For example, on March 31st, at a meeting held in the Borough road, it is reported that the Rev. G. Murphy moved the following resolution :—"That the supply of labour in this country so greatly exceeds the demand, as to cripple industry, and increase pauperism in alarming proportions. That an instant and extensive remedy is demanded ; that one of the best and most feasible remedies is the exportation of our excess of labour to the colonies, where it is needed for their development ; and that the Government should be at once urged to give the subject its earnest consideration."

For my own part, I must confess to have no great faith in either of the expedients for getting rid of indigence proposed by Dr. Stallard, Dr. Hardwicke, or by the Rev. G. Murphy. Not that I do not think much *temporary good* might be done in the present frightful crisis of poverty which so overwhelms portions of our gigantic city, London, by employing in large sanitary works, such as the widening of streets and beautifying these weary and hideous districts inhabited by our poorer brethren, as well as by the erection of numerous houses for the working-classes, to make up for those recently destroyed by the railway companies. But all such works are merely, I assert, expedients for the present moment. Can emigration promise us anything towards the radical cure or prevention of this anti-hygienic pest, poverty ? No ! Let us listen on this question to the political economy of the benevolent Scottish divine, Chalmers. In his *Principles of Political Economy*, Edition, 1856, he says :—"The felt necessity of emigration from a country is, in itself, a practical evidence that its resources are not illimitable. We may rest assured that, if other remedies for the destitution of the people were at hand, they would have the preference over this. Could home colonization, or the invention of new employments, or the increase of capital, or the opening of foreign trade, have furnished ready and withal indefinite resources for over-population, we should never have witnessed to any great extent among them a disposition to renounce the scenes of their infancy, with all the charms and associations of home, for the chances and perils of distant and unknown lands. . . . Population, when permitted its full development, by an unbounded supply of the means of subsistence, can double itself in fifteen years ; and we proceed on a computation greatly more moderate than this, when we affirm, that for an emigration sufficient to allow an unchecked multiplication of our species in the British Islands, there would require to be at least half a million of human beings transplanted annually from our shores." Chalmers, indeed, and in this I agree with him as a general thesis, to which the emigration from Ireland is an apparent exception, although the agonies caused by that terrible exodus of a nation must have been awful beyond our imagination, thinks that the belief in emigration is a most dangerous and fallacious one : and that, whenever emigration is habitual to a great distance, it is a token of a great suffering among the poorest, and indeed in many higher strata of the society whence it proceeds.

Many of the French writers on political economy hold views similar to those of Chalmers. Among others I may cite the admirable work "*Sur la Population*," by Joseph Garnier, as a proof how little emigration is believed in by the ablest thinkers in France. M. Hermann Merivale, again, in a paper on the "utility of colonisation," read at the British Association Meeting, at Cambridge, thinks that emigration has given us a great advantage over France recently. To this view I demur *in toto*. My own experience of the life of the working classes in France would not allow me to grant the assumption, that the English workmen is better off than the Frenchman. But M. Block, a French statistician of eminence, is quite "English" in his lamentations, as to the ultra-prudent character of his peasant countrymen. Thus Mrs. Grote, wife of *the* historian of Greece, in her "collected papers," quotes the following extract from M. Block's writings. Speaking of the French town artizans, that gentleman says, "Once married, many of them are careful to have no more offspring than can be competently provided for, and can be fairly endowed at the death of their parents. This habit is likewise adopted in many of the rural districts. It is affirmed, indeed, that in several of our departments, the peasantry habitually limit their families to two children. If France does not possess more numerous colonies, it is because children do not swarm with us as they do in England, and that, consequently, we possess not the amount of over-population requisite to set up fresh communities."

To this the lady authoress, Mrs. Grote, replies with great boldness, and with perfect truth. "Few persons can, I think, fail to perceive, in the almost ludicrous lamentations of M. Block, the source of the difference in the condition of the French people, taken as a whole, and the English. Those to whose imaginations the ideas of boundless wealth carry unmixed delight and pride, will deem the English form of existence the preferable one. But persons of a really philanthropic turn of mind, will probably regard the prudent, independent habits of the French Peasant with approving sympathy. Nay, they may even come to regard the advantage of setting up distant colonies as dearly purchased by the painful sacrifice involved on a system of inconsiderate, improvident multiplication of families, necessitating, as a last resource against famine, an expatriation from country, conjoined with, possibly, a life-long separation from home, and friends."

It is not necessary, surely, to explain, that both infanticide and abortion are much rarer in France, than in England. The laws of France are particularly stringent against such practices, and hence, it is well known that "conjugal prudence," as it is called, is the form which restrains on over-population takes in France. I merely advert to this, because it seems to be thought by some amongst us impossible to restrain our over-crowding, except by those methods of emigration, which have this half century been proved to be such miserable failures. Not that much sentimental hatred is not felt in France to any such "conjugal prudence." Mr. Joseph Garnier, indeed, states, that the catholic priesthood are accustomed to represent to their patients, that such prudence is "le plus damnable des péchés mortels." It must be added, however, that the French peasantry, with rare exceptions, seem to care very little for these anti-utilitarian doctrines of the reverend fathers, and prefer a couple of well-fed and happy children to eight or ten unfortunate and ill-fated offspring. The Pope and Cardinals may ere long give way upon this point, and follow Chalmers and Whately.

Emigration, even from the Eastern to the Western States of America, appears not to be rapid enough to remove the over-population of New York or Boston. How much less will it ever be able to accomplish for the inhabitants of our great hives of industry, London, Paris, Manchester, or Glasgow? The great remedy, I must confess, for poverty, and also for preventing infanticide and other evils, such as prostitution and its concomitant contagions, lies in the "conjugal prudence" of the French. Not that manifest objections do not exist to this said prudence. It *is* an evil; but, then, the condition of our race on this planet is such that we tend, like all other animals, to starve each other if we increase too rapidly. Hence, as emigration is a failure, it behoves us, if we wish to prevent poverty and its concomitants—consumption, fevers, and misery of all kinds and shapes—to look our fate full in the face, and see whether early marriage and "conjugal prudence" would not be a better preventitive of poverty than either emigration, new poor-laws, or the many panaceas of socialism and anti-political economical writers. Medical men would wonder at anyone who denied the truth of the science of physiology; but some of us, and among others the learned Dr. MacCormac, in a most interesting and benevolent paper in the pages of the MEDICAL PRESS AND CIRCULAR recently, do not hesitate to deny entirely the leading doctrine of *a science*, which appears to us as well established as are the truths of astronomy or of chemistry, the Malthusian law of population. I humbly ask permission to direct the attention of such heretics to the works of J. S. Mill, Chalmer, Garnier, and Whately.

Hospital Reports.

METROPOLITAN FREE HOSPITAL AND FARRINGDON DISPENSARY.

CASES OF SYPHILIS TREATED WITHOUT MERCURY.

By CHARLES R. DRYSDALE, M.D., M.R.C.P., F.R.C.S.,

AND

ROBERT W. DUNN, Esq., M.R.C.S.,

A part of which was read at the Harveian Society on March 18, 1869.

(Continued from page 268.)

THE following case of double iritis is still under observation:—Emily A., aged forty-eight, Hatton Garden, came to Farringdon Dispensary, September 1, 1868, complaining of painful micturition, for which infusion of buchu was prescribed. October 4th. She presented spots of syphilitic eruption on the forehead, of a dusky ham-red colour, and commencing iritis of the right eye—namely, slight intolerance of light, circumorbital deep-seated pain, triangular pupil, and muddiness of the iris from effusion of lymph. ℞ Potassæ chloratis, ʒj., gr. xv.; acidi hydrochlorici diluti, ʒiss.; aquæ ad., ℥j., t. d. s.; and to drop in the following lotion (atropiæ sulphatis, gr. ij., aq. dest. ℥j.) into the eye twice daily. 12th. Vision greatly impaired; rep. omnia. 15th. A little better. 19th. Going on well. 29th. Much better; sees pretty well, and can read with the diseased eye; pupil still slightly triangular. December 10th. Iritis of other eye; treatment as before; eruption of ham-coloured hue on forehead and over the face, which is of a fiery colour. 24th. Perfect vision in both eyes, and eruption, though still severe, not quite so pronounced and fiery. Still attending the dispensary.

At the present time there can be no doubt that a considerable number of able practitioners have nearly entirely abandoned the use of mercury in the treatment of the eruptive stage of syphilis in adults; but, as far as our personal experience goes, it has appeared to us that there is still a very general belief in the efficacy of grey powder or inunction in the treatment of the syphilis of infants, or hereditary infantile cases. Indeed, Dr. Jenner, in his recent evidence before the Admiralty, spoke exceedingly strongly as to the absolute *necessity* of the administration of mercury in such cases. The authors of this paper are not able to coincide in these opinions. Indeed, one of them, Dr. Drysdale, was first of all led to doubt the efficacy of mercury in syphilis by watching its effects upon such cases, in many of which inunction and grey powder had seemed rather hurtful. This led him to try a symptomatic treatment, and in 1862 he treated a case of hereditary infantile syphilis in this way, which recovered and is, he believes, now alive and well. Nevertheless, the authors have found that, under all methods of treatment, the disease in hereditary infantile cases is apt very often to end fatally. Mr. Dunn has now collected notes of 85 cases of infantile syphilis treated by him without mercury, of whom 13 died. This appears to be a very excellent result, far better, it is believed, than the plan of treatment by mercury with chalk or inunction would yield. But it is evident that a comparative trial of the two methods ought, in the interests of truth, to be instituted. The disease has also been extensively treated in infants without mercury in Christiania. It is time that dogmatism should be abandoned, and inquiry take its place.

Probably, the addition of a greater number of cases of constitutional disease would only weary, and perhaps tend to complicate a simple enough question. The authors of this paper are inclined to sum up their views briefly as follows :—

1stly.—Constitutional syphilis, when treated simply, tends of itself gradually to leave the system in the majority of cases, so that no further symptoms appear in the patient, or in his or her offspring. The time required for this happy result varies from nine months to eighteen months or two years.

2ndly.—Mercury is certainly not necessary in the treatment of the majority of cases of syphilis. We believe that it is, on the contrary, very injurious, adding, as it does, a severe poisoning, if used for several months, to an already debilitated condition of system.

3rdly.—Tertiary symptoms, and even bone diseases, are found occasionally when the disease is treated without mercury, although very rarely in our experience. They are well treated by *large doses* (gr. xv., t. d.) of iodide of potassium, which doses may be continued for months or even years with apparent impunity.

4thly.—Malignant syphilis, or rupia, happily but rarely occurs, and is best treated by tonics, good food, and sometimes iodide of potassium; and the syphilis of infants, both hereditary and acquired, seems to do better without mercury than with it, although a dangerous and fatal disease in a great many cases. Mercury, then, as it is confessedly a dangerous drug, does not seem to the authors of this paper to be indicated in the treatment either of primary ulcers, secondary eruptions, or tertiary accidents.

◆

ADELAIDE HOSPITAL.

Amyloid Disease of Liver and Kidneys.

(Under the care of Dr. Little.)

James Gwynne, æt. thirty-six, occupation various; admitted February 26, 1869. He stated that thirteen years before his admission he had venereal disease, three or four sores on glans and prepuce, which came out on the fourth or fifth day after exposure to the contagion; they were very painful, secreted much yellow matter, and were followed by suppurating buboes, but not by sore throat or any eruption.

Nine years ago he went to New Zealand; his health was good while there. Five years ago he returned to Britain, and began to drink freely. Rather more than a year ago he felt himself getting very weak; he had a feeling of great oppression about the upper part of his belly, and occasional shivering fits, followed by hot and sweating stages, the entire paroxysm lasting seven or eight hours; he also vomited blood several times. He went into Glasgow Infirmary, where, he says, enlargement of liver and spleen was recognised. He got quinine draughts before the shivering fits, and was rubbed with blue ointment over the liver until his mouth was sore. At the end of two months he was discharged, feeling quite well.

For eight months he continued in good health and lived temperately. He was then much exposed to wet feet, being employed as an ostler. He commenced gradually to lose flesh and strength; the feeling of oppression across the upper part of the stomach returned; he had rigors again, and his throat got sore.

Careful inquiry failed to elicit any history of suppuration, diarrhœa, or continued discharge of any kind.

Feb. 26th.—On admission, much emaciated, so weak that he can hardly walk; face rather earthy looking, skin of rest of body shrivelled, dry, and rough to a degree; tongue clean; no appetite; complains of thirst: bowels regular; never had piles; liver dulness to upper edge of fifth rib, and to an inch above umbilicus; left lobe projects an inch and a half below left ribs; pressure on liver gives great pain. There is marked increase of splenic dulness, and the inguinal glands are slightly enlarged and hard; he has a rigor every five or six days; passes 76 ounces of pale straw-coloured urine in twenty-four hours, sp. gr. 1010, coagulable to one-fifth. Under the microscope, a very few fragments of tube casts, granular and epithelial, are seen. Is very hoarse; some prominent red follicles can be seen on the back of throat; pressure over the thyroid cartilage gives great pain; he is always hawking up ropy mucus. Treated simply, by getting plenty of nourishment.

March 1st.—Tincture of iodine to the thyroid region. A draught containing tinct. opii 20 m., ether. sulph. fl. dr. j. ordered if rigor comes on.

March 12th.—Tongue only very slightly furred. Cannot be got to take food, as whenever he drinks, wind seems to meet the drink, and he throws it off with very sour fluid, and if he has been taking milk it returns curdled. He refers his great distress to the epigastrium, where—rather to the right side—there is a bulging rising out of the general enlargement of the liver, in this he says he feels a "beeling" pain; has not the same dragging feeling in the right side, when he lies on his left side, which he had on admission. Area of hepatic and splenic dulness unchanged since his admission. Bowels act three or four times daily, with griping, the fæcal matter passed being slate-coloured. Pulse 80, feeble. Since admission, only one pronounced rigor, but every morning, about one, he has a chilliness, followed by burning heat of palms and soles, but no sweating. The skin remains parched, scaly, and shrivelled; but, during past few days, there has been an eruption of small pustules over the entire body. Soreness over larynx less since the iodine was applied. Requires morphia to make him sleep. Ordered milk, and to be packed in hot wet blanket every night.

March 16th.—The wet packing made him much more comfortable at night, but he became gradually weaker, refusing everything but wine and water, and this was vomited. For past three days has passed only a few ounces of urine daily, which was exceedingly coagulable.

Post-mortem examination, March.—Great enlargement of liver and kidneys, which presented typical amyloid characters, and reaction with iodine; spleen enlarged, but apparently only from fulness of blood; not amyloid.

In this case there was an absence of both of the conditions which usually precede amyloid disease; the man had not suffered from any wasting discharge, and the venereal disease was clearly not syphilis; there were also symptoms which do not usually accompany that degeneration, rigor-marked pain, and tenderness; and, if the patients' statement was correct, hematemesis. In favour of the diagnosis of amyloid disease was the smooth resisting surface of the liver, but particularly the characters of the urine, which were markedly those of the amyloid form of Bright's Disease.

Chronic Bronchitis with profuse Secretion.—In this condition a trial is now being made in the hospital of the inhalation of steam slightly charged with the carbolate of iodine or colourless tincture of iodine, a preparation made by Dr. Evans, of Dawson Street, which seems suitable for exhibition in this form, though its great excellence lies in its virtues as an external application. The use of the ordinary tincture of iodine to enlarged glands in the neck has the serious disadvantage that, by reason of the ugly marks it leaves, it prevents those who use it from appearing in public, while they are the very persons to whom fresh air is so necessary; this elegant preparation, on the contrary, may be applied freely without the least discolouration, and without producing any severe irritation, which experience has shown to be injurious in such cases.

◆

PHENIC ACID IN SYPHILIS.

Dr. Minteforte (in the Italian *Journal of Venereal Diseases &c.*) recommends the application to syphilitic ulcers of a solution of phenic acid in water, 5 parts to 100. Dr. Fidele de Fieri extols the deuto-phosphate of mercury, one grain a day continued for two months, in tertiary syphilis.

Transactions of Societies.

ST. ANDREWS MEDICAL GRADUATES' ASSOCIATION.

A General Session of the Association was held at the rooms of the Medical Society of London on Thursday, the 8th of April; the President, Mr. Richardson, F.R.S. in the chair.

Prof. Eckhards' communication on "Hyduria" was postponed, in consequence of a sudden inability to leave Germany.

A discussion took place on the restriction of the number of Medical Graduates to ten annually. The following memorandum by the Honorary Secretary, Dr. Sedgwick, was read:—

MEMORANDUM on the Regulations concerning the Conferring of Medical Degrees by the University of St. Andrews on Persons who have not kept Terms at a University.

For a long series of years the University of St. Andrews was empowered to confer the Degrees of Doctor of Medicine after examination, on practitioners who had not received their education there.

The Universities (Scotland) Act appointed certain Commissioners to revise the regulations generally of the Scotch Universities; and they were instructed to "provide that, in so far as shall be practicable, and, in the opinion of the Commissioners, conducive to the well-being of the Universities, and to the advancement of learning, the course of study, the manner of examination, and the conditions under which degrees are to be conferred, shall be uniform in all the Universities of Scotland."

In accordance with these powers the Commissioners issued certain ordinances regulating, among other matters, the conferring of Medical Degrees, and they explained in a Report to Her Majesty the Queen the nature and effect of these ordinances, and of the provisions of the Act itself.

In their Report the Commissioners say, that "the peculiar circumstances of the University of St. Andrews afforded grounds, in our opinion, for not insisting on absolute uniformity in every respect." And so they did not require "in St. Andrews, as in the other Universities, that every candidate should have passed one of his four years of study in the University itself." But they required in all ordinary cases that two of the four years of study should have been spent in a University."

In reference to the ancient power of conferring Medical Degrees on non-resident candidates after examination, they say:—"It was, however, represented to us, on the part of the Senatus Academicus, that instances sometimes occured in which medical practitioners, who had commenced the study of their profession without the intention of proceeding to a University Degree, were desirous, after a successful career of some years, of attaining a higher professional position; and that the absence of any restriction as to the schools in which Candidates for the St. Andrews degree might have received their education, had hitherto enabled such persons to accomplish that object. The names of gentlemen of eminence in their profession, who had graduated in St. Andrews, were mentioned to us, and we ascertained, that in the medical profession a general opinion prevails that such a facility as that which the University has been in use to afford, is proper and advantageous if confined within due limits. Proceeding on this opinion, and after making the most diligent enquiries as to the number of persons on whom it might be desirable to confer a degree under such exceptional circumstances, we resolved to empower the University of St. Andrews to grant the degree of Doctor of Medicine to registered medical practitioners of established position, without restriction as to the schools at which they had received their education, on their satisfying the Medical Examiners of the sufficiency of their professional knowledge; but, at the same time, we thought it neccessary, with the view of preventing any abuse of the privilege, to limit to ten the number of degrees which should be so conferred in any one year. That number, we were assured on the best professional authority, would be quite sufficient to include all persons so situated, who could present any reasonable claim for admission to a degree."

The Regulation thus referred to, Section XX. of Ordinance No. 19, is as follows:—"The Degree of Doctor of Medicine may be conferred by the University of St. Andrews on any registered Medical Practitioner above the age of forty years, whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the Medical Examiners of the sufficiency of his professional knowledge: Provided always, that degrees shall not be conferred under this section to a greater number than ten in any one year."

The Commissioners foresaw that the regulations they framed would very greatly diminish the number of degrees conferred by the University of St. Andrews, and they looked forward to such a result with no regret in the case of a University possessing no Medical School. In their report of December 20, 1861, they say "It did not belong to the Commissioners to entertain any question as to the expediency of the University of St. Andrews possessing the power of granting Medical Degrees, as the Commissioners were not conferring that power on the University, and had no authority to take it away. But it appeared to them to be their duty to consider in what manner the system might be regulated, so as to insure, as far as possible, that the power which the University undoubtedly possesses should be exercised with due regard to the credit of the University and the interests of the public." And in their final general Report to Her Majesty they add:—"The principal object which we proposed to ourselves in the Ordinance, was to insure that no degrees should be conferred, except on persons possessed of sufficiently high qualifications."

On an examination of the place of education of the candidates "for the degree of M.D., they find that they are almost entirely persons educated and resident in England or Ireland, and in no way connected with St. Andrews." This the Commissioners consider objectionable, and they assert that "there is no occasion for persons educated in England to resort to St. Andrews for a Medical Degree, as a licence of and of the London Medical Corporations suffices to admit them to practice; and, if they aspire to a degree, it appears more natural that they should present themselves as candidates to the University of London."

The right of the University of St. Andrews to confer Medical Degrees upon candidates who have not kept terms there, but who have been a certain time in actual practice, or who hold a recognised diploma in medicine or surgery, is admitted.

That this power may be exercised with advantage to the profession of medicine is also admitted, and that the recipients of the degree are men of recognised worth is shown by the fact that Graduates of St. Andrews are attached as Lecturers, Physicians, or Surgeons, to nearly all the Schools of Medicine and Hospitals in London, and the large towns of the kingdom.

That such a power is of advantage to the public necessarily follows.

But this power should be confined within due limits, and should be exercised, as the Commissioners say, with "due regard to the credit of the University and the interests of the public." And so they ordain certain regulations, in order that the Degree may be conferred on none but "persons possessed of sufficiently high qualifications."

It would follow, then, that the provisions regulating such a power, advantageous alike to the profession and the public, should not only exclude all unworthy persons, but should also exclude no worthy candidates.

This cannot be done by a limitation in the number of Degrees which the University is empowered to grant annually, for it may well happen that in some years more than the specified number may be found worthy of the Degree, some of whom must, by this restriction to ten, be rejected, so not only an injustice be done to individuals, but an injury inflicted on the University.

It would seem to be just to require of candidates for the Medical Degrees who have not kept terms at a University that they should, in lieu thereof, show that they have been a certain time in the actual practice of their profession; but the present requirements of nineteen years is much too long. All the advantages of such a provision would be obtained by requiring all candidates to show that they have been for five years possessed of a Medical or Surgical qualification, such as would entitle them to be registered under the provisions of the Medical Act.

For such persons a searching and extended examination should be accepted as the sufficient test of qualification for a Degree. The Commissioners have provided a staff of examiners to test the knowledge of candidates in all the branches of Medical Science, and the power of visitation of examinations possessed by the General Council of Medical Education and Registration of the United Kingdom ensures the honest and faithful execution of their duty.

The Commissioners are in error when they state that there is no occasion for persons educated in England who aspire to a Degree to resort to St. Andrews, as they may present themselves to the University of London. The regulations of the latter University do not provide for the cases of Medical Practitioners, who, after a successful career of some years, are desirous of obtaining the degree of M.D., inasmuch as an attendance of several courses of lectures at a recognised Medical School is required between the first and second examinations for the Degree of M.B.; a condition obviously generally impossible to be fulfilled by a person in actual practice. St. Andrews is the only University where such men can obtain a Degree.

By the present regulations many persons well qualified for the Degree of Doctor of Medicine are prevented from obtaining it at a time when it might be of service to them.

If the minimum age at which the candidates might offer themselves were reduced by requiring five years of actual practice, and the number admitted was only limited by the stringency of the examination, the credit of the University, the interests of the public, and the honour of the Degree would be sustained, while no unworthy person would be able to graduate.

After an animated discussion, in which Drs. Wynn, Williams, Crisp, Drysdale; Phys. Williams, Tilbury Fox, Billing, Bloxam, and H. Day took part, the memorandum was received and adopted, and the Council were instructed to take such measures for bringing the subject before the University Court as they might deem best.

An interesting account of some experiments with hackisch, on himself and two friends, by Professor Polli, of Milan, was communicated by the President, who related his personal experience of an overdose of morphia, given him by mistake.

Dr. Cordwent, of Taunton, communicated a case of sudden death immediately after delivery in the upright posture, in which air was found in the coronary vein of the stomach, and showed a specimen of phosphatic calculus, removed from an old standing perineal fistula.

An important paper by Professor Eckhard, of Giessen, was then read, in which the learned author passed in review the current doctrines of the cause of the motions of the iris, and related the results of experiments performed in his own laboratory by Dr. Knoll, to elucidate the matter. The paper is printed in full in the second volume of the Transactions of the Association, which is now passing through the press.

Much interest was felt in the election of Assessor of the General Council, which was then in progress, and all were unanimous in support of Dr. Richardson.

◆

THE ARMY MEDICAL CHIRURGICAL SOCIETY OF PORTSMOUTH.

April 7, 1869.

Deputy Inspector-General Dr. C. A. Gordon, C.B., in the Chair.

Dr. Stone, R.N., read a paper on

MEDICINE AND SURGERY IN JAPAN,

in the course of which the principal diseases of that country were briefly discussed. Small-pox, which is very prevalent there, has decreased considerably in several districts since vaccination came to be practised, the general mortality having sensibly diminished since its introduction. Syphilis, which is very rife, has been inherent to the country several centuries. Of late a system of periodical medical examination of prostitutes has been instituted at the chief open ports by the native government; keepers of houses of resort are licensed and taxed. The girls are usually sold by needy parents for definite periods to the proprietors of these places, and on the completion of their period of service return to their homes, no social slur attaching to them on account of their previous life. Within the last eighteen months the services of an English naval surgeon have been secured at Yokohama in connection with a system of lock hospitals. Rheumatism, scabies, elephantiasis, pulmonary diseases, and an intractable native affection called the "stomach pain," probably a species of ulceration, were also enumerated.

The evidently European origin of their present ideas of medical practice, and the Dutch instrumentality by which this was brought about, were commented upon. Mention was also made of the Medical School at Nagasaki, under the superintendence of Dr. Baudwin, a Dutch military surgeon. One unfortunate circumstance which acts as a bar to the acquirement of sound knowledge amongst the Japanese students is the prohibition of dissections. Dr. Baudwin, however, endeavours to make up for this by the use of elaborate plates. The universal use in Japan of our chief medicines, as iodide of potassium, sulphate of quinine, mercury, &c., &c., is an interesting fact.

Dr. O'Leary, Honorary Secretary, then read a paper giving the details of three cases of aneurism which came under the observation of Staff Assistant-Surgeon Lamb, while on service in New Zealand and Tasmania. First case.—A man of the Army Hospital Corps presented himself at the General Hospital, Auckland, stating he had a bubo in right groin. On examination, the swelling proved to be an aneurism (about the size of an orange), just under Poupart's ligament, and constricted by it. At this time a bruit was audible to any person standing by the patient's bed. His statement was, that about ten days previously, while lifting a large case, he felt something give way in his groin. Pressure was applied at the distal side of the tumour, and he was put on low diet, the result of which was that the pulsation diminished in force, and the tumour became solid, but increased in size, and continued to do so till it affected the respiration by its pressure on the diaphragm. He gradually became worse, and eventually died. The *post-mortem* disclosed an enormous aneurism, extending from about six inches below Poupart's ligament up to the diaphragm, occupying the entire right side of the abdomen, pushing the liver and kidney in front of it and to the other side. The original opening in the artery was just under Poupart's ligament, and was directed backward against the brim of the pelvis, which was partly absorbed by the pressure; it had then forced its way under the peritoneum upwards on the psoas and iliacus muscles. Across the anterior surface of the tumour passed the external iliac artery. All the muscles between the tuberosity of the ischium and the lesser trochanter were disintegrated, and there was a cavity containing about a quart of semi-fluid blood.

The next case was that of a gentleman who had sold out of the army and settled in New Zealand, a robust, healthy looking, and temperate man. He suddenly slipped off his chair while sitting in the drawing-room and died. The *post-mortem* disclosed the pericardium full of blood, which had escaped from the rupture of a very small aneurism about half an inch above the right coronary artery. The sac was just large enough to admit the top of the little finger.

The third case was that of a private in the 2nd Battalion 14th Regiment, who was admitted into hospital with symptoms of lumbago, soon followed by intense pain down the left thigh, and particularly referred to one spot just above the patella. The most careful examination failed to detect any tumour or bruit, though one was suspected in the abdomen, probably pressing on the anterior crural nerve. He died rather suddenly. The *post-mortem* showed a large quantity of fluid blood in the left side of the abdomen, and lying on the psoas muscle was a large pyriform aneurism of the abdominal aorta opposite the first and second lumbar vertebræ, the bodies of which were absorbed almost entirely, the intervening cartilage being unaffected. Across the anterior surface of the aneurism passed the anterior crural nerve, stretched and flattened out, and its fibres separated. The kidney on that side had almost disappeared. The point of interest in this case was the existence of so large an aneurism, receiving its current of blood from the aorta, and issuing at a right angle to the course of that vessel, without any bruit being audible, or any other physical sign to establish the true nature of the disease.

A paper by Surgeon Porter, 97th Regiment, followed, on a

CASE OF POPLITEAL ANEURISM CURED BY COMPRESSION.

This man was admitted to hospital complaining of pain in left knee, numbness and stiffness of joint, and attacks of cramp of calf. On examination, a pulsating tumour about the size of a hen's egg was found on the outside of the medial line of the popliteal space. There was a loud rough bruit, which disappeared on pressure being applied to the femoral artery. Signosmi's tourniquet was applied at intervals extending over a period of six days, and making in all seventy-five hours, when complete solidification of the tumour was produced. All uneasiness disappeared, and the man was discharged to his duty cured in exactly one month from the date of his admission.

THE SURGICAL SOCIETY OF IRELAND.

THIS society met on the evening of the 19th March, in the Albert Hall, Royal College of Surgeons. MR. WHARTON in the chair. The following members were present:—

B. Wills Richardson, Dr. Murdock, H. H. Stewart, W. D. Moore, M.D., H. G. Croly, I. W. Usher, J. R. Kirkpatrick, A. H. McClintock, T. Purcell, H. Kennedy, G. Montgomery, H. Coulton, W. T. Stoker, W. Roe, R. Bookey, G. S. Buchannon, F. McClean, jun., E. D. Mapother, Dr. Cary (Artillery), J. R. Ferguson, R. P. White, A. H. Jacob, C. F. Moore, F. T. Porter, J. A. Baker, C. H. Robinson, M. Collis, J. H. Porter, 97th Regt., W. J. Wheeler, T. E. Beatty, W. Stokes, jun., G. Beatty, E. Hamilton, B. F. McDowell, F. V. McDowell.

DISCUSSION ON MR. H. G. CROLY'S PAPER.

MR. MAURICE COLLIS said these were most interesting cases, especially the one in which Mr. Croly stated that he had removed the submaxillary gland. It was not a promising case, the original disease having been epithelioma, and the society would look with interest to the future record of it. He had removed the submaxillary gland for cystic disease. The tumour was a very malignant one, although not cancer, and the hæmorrhage in that case gave him a great deal of trouble. In tearing out the tumour a considerable artery poured forth blood. He tied it two or three times, and on getting a momentary glimpse of it in the interval of sponging, he found the nutrient vessel of the tumour had been torn across at its origin, and this it was which caused the difficulty in dealing with the hæmorrhage. He was glad to see Mr. Croly holding to the good principle of conservative surgery in these cases. The removal of the lower half of the jaw saving the teeth, was a very valuable operation. He believed the fatality of these cases where the jaw was cut completely through was very considerable, and he might also remark with respect to those operations where a great portion of the tongue had to be removed, that he believed the great fatality in Mr. Syme's cases, and in the cases of those who had followed his plan of incision, arose from the division of the jaw. The absence of support, the constant irritation that was necessitated by it, and the consequent increase of purulent depots all lead to unfavourable results. He thought whenever it was possible to keep a portion of the jaw as a bond between the two sides, it was of the utmost importance to do so. He did not know whether Mr. Croly's section implicated the dental nerve or not. The question of treating cysts of the jaw in the manner he had described was a very important one. He thought it was only necessary, even when these cysts arrived at a large development, to remove a portion of the cyst sufficient to get out the contents to produce a cure.

DR. MAPOTHER said that about a week since, in St. Vincent's Hospital, he met with a case of extensive epithelioma of the lower lip, with glandular disease on the surface of the submaxillary gland. He did not attempt the operation of removing the submaxillary gland, and the lymphatic glands connected with it, but thought it right to remove the epithelioma of the lower lip. He must acknowledge that since then, the secondary disease of the lymphatic glands underneath the lower jaw had progressed extensively. When he operated, the disease consisted in a hardening of the gland, but it is now ulcerated, and last evening he lost half a pint of blood from it. The man himself pressed strongly for the operation, and for that reason he performed it.

MR. CROLY in reply said, he would make known to the society anything he heard of the future history of this case. He was not himself in favour of the operation, but the man pressed very hard for it, and when his colleagues thought he should get the chance, he (Mr. Croly) did not like to refuse. The wound healed with wonderful rapidity, considering that the patient was an old man. He thought in dealing with hæmorrhage in this region, it was right to remember that deep plugging was likely to be attended with mischief. The curious point in the case was that the epithelioma was at one side, and the secondary tumour at the other. In performing the operation, he went as close below the dental nerve in the horizontal section as he could, whether he cut the dental nerve he could not say, but he got out the diseased mass without much hæmorrhage. He had known cases of this kind where the tumour having been punctured, gave exit to a dark coloured fluid, composed of blood and serum, which on examination, was found to be cancer. In this instance he avoided puncturing the tumour, in order that this cancer juice might not escape and extravasate into the neck. The man got better rapidly, but he would not be surprised to hear of the return of the disease.

Mr. WILLIAM STOKES read a paper on

MR. WHARTON'S MODIFICATION OF TEALE'S AMPUTATION BY RECTANGULAR FLAPS.

There are few topics in surgery which have of late years more actively engaged the attention of operating surgeons than that of determining the method of amputation of the thigh which is fraught with least danger to the patient, and affords the most satisfactory results, not only as regards the appearance, but also the form of stump which can be best adopted for the subsequent application of mechanical appliances. Among these methods may be mentioned those of Verduin, Sedillot, B. Bell, Vermale, Liston, Langenbeck, Velpeau, Gritthey, Syme, Spence, Teale, Carden, and others. There has been, and there still are, many advocates for each of the operations with which the names I have mentioned are associated—a fact which shows that the opinion of surgeons is still to a great extent unsettled as to the mode of amputation which, in every respect, yields the most satisfactory results.

There can be little doubt that of the comparatively novel procedures the "rectangular method," suggested first by the late Mr. T. Pridgin Teale, the eminent surgeon of Leeds, is one which, perhaps more than any other, has found favour among surgeons. This results from the advantages of this operation, which are doubtless familiar to the majority of those present, and which it is, therefore, unnecessary to enumerate. However, objections have been raised to this method which are not by any means devoid of foundation. These are—1st, the great extent of cut surface that the operation necessitates; 2nd, the longitudinal division of muscular tissue; and 3rd, the high division of the bone. The amputations of Spence, of Edinburgh, of Carden, of Worcester, and lastly, the operation which is the subject of this communication, get rid to a great extent of these so-called defects. Mr. Spence's operation appears to be allied to Mr. Wharton's modification, as it consists of a long anterior oval flap, and no posterior one; but it differs from it in one essential particular, that it involves as high a division of the bone as in the rectangular operation of Mr. Teale. Of Mr. Carden's operation, the amputation by a long anterior skin flap, notwithstanding the favourable accounts he gives of his results in a paper which he read at a meeting of one of the provincial branches of the British Medical Association, and published in a separate form in 1864, I cannot think highly, though I have not, it is true, practised it on the living. Yet I have frequently performed the operation on the dead subject, and the unfavourable impression I formed of it was, to a great extent, confirmed by seeing two cases—one in University College Hospital, and the other in the Dreadnought Hospital Ship, at Greenwich—in both of which cases the flap sloughed. The operation, therefore, which seems to me to get rid best of two of the supposed defects in Teale's amputation—viz., the extensive division of muscular tissue, and the high division of the bone—is the method which has been suggested in the *Dublin Quarterly Journal* for November, 1868, by my friend, Mr. Wharton.

It is, I believe, an undisputed fact that, at all events in amputations of the thigh, the nearer to the trunk the bone is divided the greater is the risk to the patient.

Dieffenbach, in one of his lectures on amputations of the thigh, pithily expresses this in the sentence, "Zollweisi steigt die Gefahr," which, freely rendered in English, means, "the danger increases by the inch." Any modification, therefore, of the methods of the rectangular amputation, which has for its object the saving of bone, and which, in all other respects, affords equally good results as in the cases where the operation has been performed without any deviation from the plan laid down by Teale, must obviously be an improvement. The modification may be given in Mr. Wharton's words:—"Let the measurements for Teale's amputation be accurately taken and mapped out, but instead of dividing the bone—I am now specially referring to the thigh, at the site directed by him—let it be sawn at the situation corresponding to the inferior termination of *his* posterior flap, and let the superior boundary of the anterior flap be limited by the same plane. The saving of bone thus effected will be considerable, and therefore tend directly to diminish the mortality of thigh amputations. Ac-

INEBRIATE ASYLUMS.

(Continued from page 313.)

INEBRIETY A DISEASE.

WE find in a biographical notice of a celebrated man, who himself was an instance of the case described, the following words: "In the same unfortunate direction was the tendency of a habit grown insidiously upon him—a habit against the damning control of which he wrestled with an earnestness indescribable, resorting to all remedial expedients which professional skill, or his own experience, could suggest, but never delivering himself entirely from its inexorable mastery."

No thinking man can be blind to such qualities and struggles in one who is near and dear to him, and whose character he intimately knows, without being convinced that of whatever faults he may be guilty, it is not the result of that wilful malicious preference for evil which constitutes criminalty and justifies punishment; consequently the more intelligent of the community have been led to the conviction that inebriety is a disease, an abnormal condition of nerve matter, and a proper subject for remedial, rather than coercive, treatment.

The fundamental basis upon which all hopeful treatment must rest, lies in the desire of the patient himself to escape from the slavery that enthralls him. But little if anything can be accomplished in opposition to the wishes of the person to be treated, and it is a melancholy fact that cases do exist of those so naturally base, or debauched by long indulgence, that no aspirations for better things can be excited within them, and no effort can stimulate them to that personal exertion which their salvation demands. But in a vast majority of cases we may confidently rely upon the hearty co-operation of the patients themselves. It would surprise one not familiar with the fact to be made aware of the almost universal desire for reformation, and of the power of self-control which animates the soul, even of those who are hopelessly abandoned by their friends as sunk in irreclaimable degradation and vice.

We know from experience in hundreds of cases, and from extensive intercourse and correspondence with this very class, that it would not be too much to say, that thousands in our land are listening with unutterable longing for some authentic voice to sound the glad promise of relief—who make it their prayer by day, and their dream by night, that some brazen serpent may be lifted in the wilderness in which they have fallen, to which they can look and live again.

In over two thousand cases of which I have been cognizant, ready submission to, and co-operation with, treatment have been universal, and in a large majority of cases this compliance with the means of recovery has been prompted solely by the patient himself, whose eagerness would not allow him to wait even for the advice or urgency of friends.

Indeed, one of the foremost and prominent advantages of seclusion is found in the fact, that, on entering upon it, the patient tacitly admits the necessity of remedial treatment in his case, and stands committed by this step to active measures in his own behalf. The man who will consent to the sacrifice of personal pride for the success of any object, has given the strongest evidence of his desire for its attainment, and can no longer be considered hopeless. All experience shows no more potent spell for the recovery of lost freedom, than the consciousness that "who would be free, himself must strike the blow."

But perhaps the strongest reason why seclusion and restraint are recommended to the inebriate in search of restoration, is because by that means, and by that only, can the great desideratum—total abstinence from everything that can intoxicate—be ensured. This is the absolute *sine qua non* to which all other treatment is subsidiary. So long as the appetite is fostered and kept alive by stealthy and repeated indulgence, all other treatment will be futile. The question of total abstinence then—now and forever—covers the whole ground of remedial treatment.

I think a large proportion, even of those deeply interested in this work, lack a correct understanding of the extent of our skill in this matter, and what is the utmost limit to which human science and effort can go in the treatment of inebriety as a disease. The appetite—whether it be idiopathic, as is sometimes the case, or induced by the habits of the past life, as it more often is—*can never be removed by any human skill*— It may be weakened by a long lapse of time, but it will never die so long as its possessor himself may live. But while it shall still have a dormant existence, so long as no drop of inflaming stimulants is allowed to feed it, it must abrogate all its vast power for evil and become the slave and subordinate to that which is strong enough to stand firm to the total abstinence principle.

Experience has shown a thousand times, with sufferers by this disease, that after the most solemn promises, and often, no doubt, with the best intentions to keep them, even after precautions have been taken to cut off the supply, the patient, by the exercise of astonishing cunning, would still nullify every effort by continual indulgence.

Even in the Asylum it is necessary to stand guard with unceasing vigilance over every avenue by which stimulants can reach those from whom it has been recently withdrawn.

A residence at the Asylum has also the merit of placing the patient constantly under the eye of the physician who has his case in charge.

No effort for renewed self-control can be made with a fair chance of success, without the co-operation, as far as possible, of a healthy physical system. The first attention then in any rational treatment must be given to a searching and patient diagnosis of whatever malady may suggest itself, and the application of the proper remedial agents.

The brain, if not already diseased, is in imminent danger. The stomach is almost sure to exhibit a morbid condition, while *Renal* and *Hepatic* diseases are very common, and we have reason to believe that the most fatal diseases, such as consumption, apoplexy, &c., often result direct from the intemperate use of stimulants. The effect of these alcoholic and narcotic poisonings can be traced in *post-mortem* examination, by lesions all through the physical system. Indeed, it is hardly too much to say, that there is not an organ of the body that is not impaired in their functions by this fatal habit.

It has often been noticed that self-control, which seemed impossible of attainment, has been found easy and natural on the removal of some physical ailment, which has had the effect to cloud the moral perceptions and demoralize the will. It will therefore be seen that the exercise of the most judicious moral restraint will often be of no avail, unless supplemented by proper medical treatment. Such treatment, dealing with diseases, sometimes of long continuance and always dangerous, must often be the work of months, and the physician will labour with greater advantage when a prescribed diet and proper sanitary regimen can be enforced, with that opportunity for close observation allowed, which can only be the case when the patient is under the physician's immediate control.

Concerning the nature of this restraint I wish to say a word or two. We know well that everything which has the appearance of restraint upon the freedom of the individual is looked upon with suspicion and aversion by our free people.

Our rule in the matter is a simple one. We impose no restraint that will not be readily acceded to by any one sincerely desirous of accomplishing the result for which he has entered the asylum. The amount of liberty granted must vary somewhat with the nature of the case, but it will be the largest that in the judgment of the Superintending Physician the patient will admit of. In cases of those who will not abuse it, the leaning is always towards additional liberty rather than towards additional restraint.

There is one class of patients, however, who are exceptions to the general rule; who, either from absolute weakness and entire deficiency of self-control, or else from mere malice, will abuse every liberty accorded them, and seize every opportunity to violate such rules of the Asylum as are essential to the comfort and happiness of all. There is but one course open to such cases, either to benefit them, or to restrain them from demoralizing and injuring others, and that is to place them in such confinement as will effectually restrain them, until either the power of volition is strengthened up to the point of resistance, or they are coerced into some respect for themselves and others. These are exceptional cases, however, and I have often seen such become new men, and truly reformed.

It is only after patient thought and experiment, sometimes often repeated, that the proper remedies are administered, and such influences brought into action as shall best "minister to a mind diseased."

Such evidences as these furnish us the comforting assurance that "our labour is not vain in the Lord," and that in our efforts to break the strongest link in that chain with which sin has held the human soul, we are following in the footsteps of Him "who came to preach deliverance to the captive, and the opening of the prison doors to them that are bound."

In closing I propose briefly to submit to you the result of our work during the last eight months. As it appears, there have been admitted eighty patients, forty-two from the State of New York, thirty-eight from other States. Their average age is thirty-one years. Thirty-five married, and forty-five single. Forty have been discharged. Forty are now remaining. None have died.

There is not a profession but that has its representatives here, and we see on our roll the names of merchants, artisans, mechanics, farmers, and one or more from almost every trade and calling. With but few exceptions, they have evinced a desire for reformation by obedience to the rules of the Institution, and I have not the least doubt that most of them will attain the high position they seek—a life of sobriety and usefulness.

Should any one estimate the pecuniary value to the state of a sober industrious man, compared to that of a drunken man, who must be only a burden to the State, it will be found that money spent judiciously for the reformation of the inebriate will return to the public treasury a larger interest than any other investment. But this is taking a mere cold pecuniary view of the matter. Look at the father returned to his family a reformed man! His children are now clothed and educated. The vacant place in the Church and Sabbath School is again filled. His farm, his workshop, his counting room, or his professional office is once more attended to, and the life blood of the community is quickened and enriched by the restoration of one of its members. Every fibre of the body politic feels its influence. Therefore we are not engaged in a mere speculative work, without an ample return for money expended.

◆

SCOTLAND.

UNIVERSITY OF ABERDEEN.

THE COURT.—THE GENERAL COUNCIL.

The University Court met on Monday, the 12th, when an important discussion took place as to the admission of reporters. Eventually the following resolution, proposed by Dr. Pirie, was carried :—

"That all cases which involve the exercise of discipline or comparison of professional qualifications, which the Court may deem it for the interest of the University to consider in private, shall be preliminary, and shall be determined before the Court is opened. That representations of the General Council, or other matters of public interest, shall be considered subsequently, and that the probable time of such business being brought on shall be intimated to the reporters for the press, so that they may attend and report any discussions which may take place, if they deem it desirable."

The resolutions of the last General Council, recommending greater facilities in the exchange of books at the University library, and a new catalogue, were then considered, and the following deliverance unanimously adopted :—

"The Court, while most anxious to meet the wishes of the University Council, are constrained to say that they do not know any arrangement under which the object contemplated in No. 1 of this representation could be satisfactorily attained. The Court fully recognise the importance of having a complete catalogue of the library prepared, and they have reason to believe that when the books shall be re-arranged on the shelves of the new library, the whole subject of such a catalogue will be considered by the Senatus, with special reference to the question of having it printed, and a report thereon presented to the Court."

Dr. Alexander Ogston asked the Court to fix his fee for the class of ophthalmoscopy at one guinea, but the Court were not satisfied that they had power to fix the fees of optional classes, though they considered the fee named very moderate.

Some other business was also transacted.

THE GENERAL COUNCIL.

The half-yearly meeting of this body was held on Wednesday afternoon last at Marischal College. The Principal occupied the chair.

Regulations as to printing the proceedings were adopted, which will enable distant members to receive copies on defraying the expense of postage.

The next subject discussed was the library grant, in reference to which Professor Geddes pointed out that by some mistake of making up the returns it was found that the whole value received was only £320 per annum, as compared with £525 given to St. Andrews, £630 to Edinburgh, and £707 to Glasgow. He regretted that they had not the Maitland and Bannatyne series of works in their library, as an instance of what they might have; and it was, he did think, the duty of a General Council to make such a representation to the University Court, and endeavour as far as possible to secure what they only wanted, equity and justice. (Applause.)

Some other speakers having supported these views and furnished statistics, Professor Bain, admitting that great injustice had been done to Aberdeen, said that the cause of the inequality was that other Universities in Scotland maintained their buildings, but they did not from their own funds, but at the public expense. He would state what had actually been voted to the University—1859, £6,000 for new class-rooms, new library, professors' houses; 1860, no vote; 1861, £6,870 to continue the works; 1862, £903; 1863, £1,459; 1864, £580 for repairs; 1867, £3,035; 1868, £4,805, divided in erecting a professor's house and to the library, and to Marischal College. He had not got the estimate for the present year, but he believed it contained the remaining £2,000, making in all a grand total of £25,652. This has been expended rightfully enough, and he was not prepared to say otherwise. In the face of such facts he doubted the expediency of entertainment of Professor Geddes' motion. If the Treasury were, say, to make up the grant to that of St. Andrews (£630) on the condition that they should pay for all repairs on the buildings, they would be losers by the bargain, and consequently he could not agree to the motion. (Applause.)

Professor Black, Dr. Struthers, and others having spoken, a resolution was carried by a large majority to represent the matter to the University Court with a view of the inequality being rectified. On the motion of Dr. Brown, seconded by Dr. Corbett, it was agreed to take steps towards reducing the library fees.

The last business related to the Education Bill, on which the following resolution was agreed to :—

> "That of the parties represented by the proposed Board of National Education for Scotland, none have a deeper interest in that great object than the University Councils ; that this fact has been distinctly recognised in the Education Bill for Scotland now before the House of Lords, in so far as by clause 4 of said bill it is provided that of nine members who are to constitute the board of Education, two shall be elected by the Universities of Glasgow and Aberdeen, and two by those of St. Andrews and Edinburgh, to serve for a period of years alternately ; that, nevertheless, the noble Duke who introduced that bill did, in the discussion on the second reading of said bill, signify his willingness to abandon that provison of it which gives to the University Councils power to elect two members of the Board as aforesaid ; that this Council, deeply regretting that this should be in contemplation, and persuaded that the true interests of Scottish education will be best advanced by allowing to the University Councils the position assigned to them in the bill as first brought in, do accordingly resolve to petition both Houses of Parliament not to make any such alteration in the bill as would deprive them of that place."

UNIVERSITY OF EDINBURGH.

The Professorship of Chemistry in the University has been conferred upon Alexander Crum Brown, M.A., M.D., D. Sc. (of the University of London), who, in addition to Dr. Macadam, has been for some years one of the Extra-Academical Lecturers on Chemistry. Dr. Crum Brown is the author of the graphic method of chemical notation, which has been very generally adopted, and is now used by Kekulé himself. In addition to one or two experimental papers, the new Professor has issued, in conjunction with Dr. T. R. Fraser, a book on the "Connection between Chemical Constitution and Physiological Action." This paper treats of the investigation of the physiological action of the compounds of strychnia, brucia, and other alkaloids, with the iodides of methyl and ethyl.

The installation of the Chancellor and the Ceremonial of Graduation take place this day.

PROFESSOR SYME.

The whole profession will be pleased to hear that our great surgeon is making rapid progress.

THE BLESSINGS (!) OF POVERTY.

A series of articles on "Political Economy and its Application to Popular Science Questions," is being published in the *Weekly Scotsman*. The following extract on the benefits of poverty is a good specimen of the writer's style, and worthy the attention of a profession that sees so much of poverty :—

> "One of the oldest and noisiest of cants of which this world is full, is the cant about the benefits of poverty. Perhaps nobody believes it ; but how ready most of us are to enlarge on the inexpressible blessing of having nothing ! This cant is the cardinal doctrine of asceticism. It is the cry of all the Senecas that ever lived, whether they have come as Roman stoics, preaching in purple and fine linen and with well-weighed epigrams the vanity of riches, or as Puritans, the modern stoics. It is one of the commonest, most Protean, and abiding misrepresentations of Christianity. Yet, an instinct not to be preached out of existence impels men to gather wealth, as an instinct impels bees to gather honey. Moralists and preachers notwithstanding, man goes to the mill, or the field, or the sea, as the bee to range over the wild thyme or clover. Surely for grown men it is time to cease talking as if there were affinity between brown bread and any of the cardinal virtues, or as if charity were incompatible with broadcloth worth so much a yard, and to hint that we are nearer the state of original innocence the less garments we possess, or that a man is in a good way provided he have holes in his stockings. Let him darn them, and a step is taken. We do not deny that on potatoes and dripping may be nurtured the sturdiest virtues ; but some moralists forget that the former do not insure the latter. How many things are impossibilities without wealth ? Civilisation, and all that it brings in its hands—leisure, knowledge, culture, the fine arts, and, vastly more momentous, the hope of a better lot for the millions that must now labour on unenlivened by rays of worldly prosperity, happy if they can deaden their desire of that smoothness of life which all of us at some time or other dream of—are possible only with a large accumulation of wealth. Without it there is no immunity from famine. Our ancestors, being poorer than we are, lived lives that were on an average shorter than the lives we live now ; and, if things march as we desire and hope that they will march, our children will live longer than we live. To the increase of wealth, we owe in great part political emancipation ; to the poverty of the world, we owe the very existence of slavery; for, as Aristotle long ago remarked, if the chisel and axe could work of themselves, there would be no slaves. And when a country becomes so wealthy as to be able to yoke wind, water, and steam, so that the chisel and axe do work of themselves, slavery is rendered unremunerative and antiquated—in his own interest, the master frees the slave."

THE LATE DR. SELLER.

Dr. W. Seller, whose name from his early youth has been familiar to Edinburgh men, died on Sunday week, after a severe illness of nearly three years. By his learning and talents he had gained a reputation in the profession. For many years he edited more than one medical journal. In 1862 the Royal Society presented him with a medal for his memoir of Dr. Whytt. He was President of the Royal College of Physicians from 1848 to 1850, and President of the Medico-Chirurgical Society from 1854 to 1856 ; and was honoured by the Royal College of Physicians to sit for his portrait, which now adorns their new Hall.

The remains of Dr. Seller were interred on Friday last, the Colleges of Physicians and Surgeons were represented at the funeral. The Fellows of the College of Physicians met in their hall, where they were joined by Mr. Spence, President of the College of Surgeons, and many Fellows of that body. There were also present Dr. Ormond, President of the Medico-Chirurgical Society, and many members of that association who are not Fellows of either College. These medical friends joined the funeral procession in carriages. On nearing the cemetery the carriages of the Fellows of the College of Physicians (of which body Dr. Seller had been twice President, for a long series of years a Councillor, and, at the time of his death, Morrison Lecturer), left the main body, and driving rapidly on, reached the gate before the arrival of the body, which they received drawn up and attired in their crimson and black official robes, headed by their President, Dr. Moir. The coffin having been removed from the hearse at the gate, the Fellows of the College formed two deep and preceded it to the grave, the College officer bearing the mace covered with black crape. Sir James Y. Simpson, Bart. ; the Hon. Lord Deas, Dr. Moir, President of the College ; Dr. Alex. Wood, Mr. Arch. W. Dickson, F.R.S., were pall-bearers.

PUBLIC HEALTH IN MARCH.

The Registrar-General's monthly return is unusually important :—During the month of March, there were registered in the eight principal towns of Scotland, 3,574 births, 550 marriages, and 3,218 deaths. These numbers are the highest recorded during any month of March since the Registration Act came into operation in 1855 ; and, allowance being made for increase of population, the births are 222, the marriages 47, and the deaths 618 above the average of the month during the last ten years. Previous to this, the highest monthly number of deaths was recorded in January 1864. In Glasgow, the mortality has been high beyond all precedent, the registered deaths being 53 in excess of the births. The high mortality has not been caused by the prevalence of any epidemic, but by atmospheric agencies, and in especial by the biting severity of the northerly and easterly winds which have been the prevalent aërial currents during March. These not only raised the mortality from all disease, but causes an immense increase and fatality of inflammatory affections of the respiratory organs. The zymotic (epidemic and contagious) class of diseases proved fatal to 688 persons in the eight towns, and thus constituted 21·4 per cent. of the mortality; but the actual number of deaths from that class of diseases in each town, excepting Perth, was much above what it had been in February, showing the baneful effect of the atmospheric vicissitudes even on epidemic diseases. Fevers still continue the most fatal of the epidemics, having caused 189 deaths, or 5·8 per cent. of the mortality. This rate was slightly exceeded in Glasgow, Paisley, Perth, and Aberdeen. Of the 189 deaths from fever, 126 were attributed to typhus, 46 to enteric, 3 to relapsing, 4 to simple continued, and 10 to infantile remittent fever. Hooping-cough, the next most fatal of the epidemics, caused 141 deaths, scarlatina, 100, measles, 77, diarrhœa 42, croup 32, diphtheria 15, dysentery 7, small-pox 6 (of which 5 occurred in Greenock), and metria 3. Apoplexy caused 41 deaths, paralysis 58, and diseases of the heart 124. The deaths from inflammatory affections of the respiratory organs (not including consumption, hooping-cough, or croup) amounted to 812, being more than double the number during the corresponding month of last year, and 225 above those of February 1869. The deaths from consumption alone were 408.

UNIVERSITY OF ST. ANDREWS.

Dr. Richardson, of London, has been elected Assessor by a majority of 69.

ALVA.—NEW WATER SUPPLY.

A few months ago the Parochial Board of Alva, acting as local authority, resolved to introduce a general water supply for the village. A large cistern or reservoir is in course of erection at the foot of the hill, and pipes are being laid in the streets. A number of wells will be erected at convenient places, while persons who desire it may have a supply into their houses. It is estimated that the scheme will cost between £900 and £1,000.

BLACKFORD.—FEVER.

A severe epidemic is prevalent among the inhabitants of Blackford. Several deaths have occurred, and the lives of a large number are despaired of. The low situation and imperfect drainage, together with impure and unwholesome water, are generally blamed for the outbreak.

CLIMATE OF INDIA.

Sir Alexander Grant, Principal of Edinburgh University, delivered the last of the Winter Course of Lectures under the patronage of the Young Men's Christian Association, in the Queen street Hall, on the 12th inst. The subject was his "Recollections of Western India." Speaking of its sanitary aspect, he says:—

> "As regards the question of health, the risks were undoubtedly greater in India than in this country; but he did not think they were so great as implied by the Life Assurance Companies, who nearly double a man's premium in going out to India. Much depended on the constitution and on the local climate in which a man was placed in India. There was on the whole nothing absolutely alarming in the climate of India, speaking generally, for a man of sound constitution and accurate habits. European children, from the ages of six to sixteen, could, however, hardly bear the climate, and India would hence ever remain to Europeans an encampment of warriors and pro-consuls, in which man's most abiding residence seemed after all an abiding tent only for a night."

THE SEASON AT NICE.

(FROM OUR SPECIAL CORRESPONDENT.)

Nice, April 1869.

Having given you in my last, particulars of the last illness and death of Prince Stirberg, and of the sad drowning of poor Mrs. Hill, and the accident to the Duke Caylus, I need not say we have had plenty of sensation here lately.[*] You will remember that Prince Stirberg was a Hospodar of Wallachia, and is said to have amassed a large fortune during his tenure of that office. He had resided here a dozen seasons. Like a good many other ex-potentates, he found this cosmopolitan town rather agreeable, and was content to idle away his time after the approved fashion. The drowning of Mrs. Hill made some sensation amongst the Anglo-Saxon community. She was an American, and, like some others of that go-a-head nation, would bathe on the beach at this early time of the year. This was most imprudent, considering the weather we have had to endure. Indeed, no one should attempt so summer an enjoyment here till after May. It seems to me a great absurdity, and very few will be found to do the same.

No amendment has taken place in the state of our drainage. The weather has been anything but at its best. I fancied that what we suffered early in the year would be made up to us by the beauty of this season, but I find I was mistaken—my prophesies were not fulfilled. From Cannes and Mentone just the same sort of complaints arrive. The latter, indeed, does all it can to conceal the hateful fact that it is no better off than the rest of us, and goes on declaring that the railway will really be opened to its station in time for next season, and that it will reap a golden harvest. *Nous verrons.* I have my doubts. People are beginning to find out how slight are the variations along this coast, and how foolish it is to place reliance on the differences between the climates of towns only a few miles apart. We have our attractions; they have theirs. Which are the greater, who can tell?

◆

Notes on Current Topics.

Malvern Rural Hospital.

We have received the first report of this institution, which seems likely to be a further proof of the success of the cottage hospital system, and that on an important scale. At an expense of £1,593 18s. 5d. a building has been erected for the hospital. We note with pleasure a statement that all qualified gentlemen in the district have been invited to act as surgeons to the hospital. Such union is highly commendable. The hospital is not entirely charitable, but partly provident, as each patient has to pay 5s. weekly to help the expenses. After the autumnal rains the roof let in water, and it is stated that at a trifling cost this will be remedied. We would suggest that the builders should perfect their work at their own expense.

Delbriel's Sewage Scheme.

At a meeting lately held at the Inns of Court Hotel, the proposals of M. Delbriel were brought before those present, and it was decided that full details of the scheme should shortly be published, and that at a future public meeting the machinery should be exhibited. The system is known in France, where it is practically applied in several places, as *vidance à vapeur*. By means of a locomotive or traction engine, the sewage is pumped from cesspools into a closed iron tank, from which the vapours can only escape through the fire of the furnace, being thus consumed. Even very nearly solid matter can be lifted ; and the mode of applying is to irrigate the land, by a hose from the tank, with the liquid portion, the solid being subsequently used as best it may be.

---

[*] Our Correspondent's letter referred to here has never come to hand. This is another instance of the irregularities of the post. No less than six or seven letters from Nice have miscarried lately. It is time to ask our authorities in St. Martin's-le-Grand to remonstrate. There is disgraceful mismanagement somewhere. Can it possibly be partly on this side!—Ed. M. P. & C.

Coroners.

A DEBATE in the House of Commons on the election of coroners cannot be altogether useless. The present system is so bad that any change must be an improvement.

Life Peers.

CLEARLY the day is coming when life peerages will be conferred. Will the healing art then be recognised in England? or shall we remain behind all other countries? It was once hoped that Sir B. Brodie would enter the House of Lords. Sir T. Watson would gracefully fill a senatorial seat.

Festivals.

THE anniversary festival of University College Hospital has been postponed to June 23rd. The dinner of the North London Consumption Hospital is to take place on the 30th of this month, when the Lord Mayor of London will preside. On the 24th the British Orphan Asylum Festival will be held at Willis's Rooms. The Duke of Cleveland in the chair.

Pharmacy in Italy.

FROM an official report of the Italian Minister of the Interior it appears that there are at present 10,005 *pharmaciens* in the kingdom, that is one for 2,426 inhabitants. The republic of St. Marin, on the contrary, which contains 8,400 inhabitants, has only two apothecaries. The Pontifical dominions, estimated at 800,000 inhabitants, has 300 *pharmaciens*, that is 10·307 for the whole peninsula, or one to 2,433 persons.

Fasting in Wales.

A GOOD deal of speculation has been rife respecting the so-called Welsh fasting girl, who is declared to have existed since October, 1867, without having tasted food, and for about four months last past not even water. It is said that she has been closely watched without any deception having been detected, and that a medical student took his turn in the continual watching to which the girl and her friends submitted. Tales of this kind have often been circulated, and it is to be regretted that a system of constant watching, in which a medical student took part, was not carried out more fully with a view of satisfying the many inhabitants of the place whose curiosity has been excited.

The Late Mr. Bruce.

AT the early age of twenty-seven, Alexander Bruce, M.B., M.S., F.R.C.S., one of the most promising of the hospital surgeons of London, has been carried off by fever. It is not long since we noticed a pamphlet of his, and we had hoped that our columns would contain some valuable contributions from his pen That expectation cannot now be realised, and we have only to express our sympathy with those who have lost such a relative. Since he became assistant surgeon at Westminster Hospital he had, if possible, increased the esteem in which he was held. As a teacher and friend, he was deeply respected and thoroughly loved, and his devotion to his professional duties could not but excite admiration. His race has been nobly run—brief though it was. It is impossible to say the position he might have attained had his life not been cut short.

The Dead House of St. George's-in-the East.

A DAILY paper reports the proceedings that took place at the meeting of St. George's-in-the-East vestry on Friday, when Dr. Rygate, the medical officer, referred to the report which had appeared in the morning papers of the 13th inst., as to the defective accommodation at the dead house of the parish. In the report it was stated that Dr. Budgett, the medical man who made the *post-mortem* examination in the above case, gave evidence at the inquest to the effect that in the dead house there was neither table nor chair ; and that so open was the place to the public gaze, that a mob collected to witness his proceedings, and owing to the want of light he was compelled to take the stomach out into the churchyard to examine it. Also, that there was neither towel, water, nor soap in the dead house, and that the doctor only obtained the latter by giving a pauper attendant a pecuniary consideration. The medical officer said he had visited the dead house that day and found that the charcoal bench provided by the vestry four years ago had been removed, and he recommended this should be replaced and water laid on. He could see perfectly well in every part of the building, which was, moveover quite free from being overlooked, being 180 yards from the back of the rectory. In the conversation which ensued, it was stated by various members that the mob alluded to consisted of only three persons ; that soap and towels were always kept on the premises, and that the pecuniary consideration to the pauper was not for providing any of these articles, but for sewing up the body. The attendant also declared that the stomach was never removed from the body at all, and could not have been taken into the churchyard by Dr. Budgett. It was also stated that the dead house was altered during the cholera year at the instance of the Government inspector, and every request of his complied with. Mr. Herbert complained that a *post-mortem* examination in the case was wholly unnecessary, there being ample evidence of the man having been brutally murdered by being thrown on the pavement and jumped upon in the presence of three or four witnesses, and some strong observations were made as to the overdrawn and false character of the statements which had been made.

Mr. Bird's Inhaling Pipe for Smoke or Vapour.

AMONG various interesting matters brought before the London Medical Society, at the meeting on the 14th, was the recently invented inhaling pipe of Mr. Bird, of Seymour street, which was brought forward by the President. In this pipe the solution to be inhaled is poured upon a sponge of felt wadding, attached to the lid of the pipe, and then by the act of inhalation, or suction, air is drawn in through the perforations in the lid, and so caused to pass over the saturated sponge. A small aperture in the pipe stem that can be closed at will by the thumb of the smoker, serves to dilute the vapour, if need be, with common air. When it is desirable to raise the temperature of the pipe, a small pellet of heated pipe clay is inserted before the sponge and lid are put on. The sponge is secured to the lid by a small curved wire, like a corkscrew, so that it can be removed and replaced by a fresh one most readily. Through the kindness of Messrs. Savory and Moore, a series of ethereal tincture of the Datura tatula, stramonium, pellitory, &c., were shown before the Medical Society, as adapted for use in the pipe. The President, Dr. Morell Mackenzie, Mr. Henry Lee, Mr. Dunn, Dr. Thorowgood, Dr. Routh, and other Fellows present, remarked on the utility and capabilities of the pipe. All the speakers insisted much on the importance of *inhaling* any medicated vapour for the relief of asthma, and not merely puffing the vapour in and out of the mouth as is the practice of those who smoke tobacco.

St. Andrews M.D's.

At the late meeting of the St. Andrew's Graduates Association, a memorandum was adopted, urging the propriety of abolishing the restriction to ten persons annually, as the number on which non-residential degrees should be conferred. It is not common to see such an opinion maintained by the possessors of a degree, and therefore the fact before us deserves especial attention. The whole matter of degrees and licences is at present in a very unsatisfactory state. All sorts of variations exist, but without for the most part any reason. We hope the memorandum of the association in question may be productive of some good.

Bequests to Medical Charities.

By the will of General Sir A. B. Clifton, G.C.B., whose personalty was sworn under £140,000, St. George's Hospital, London, the Sussex Hospital, Brighton, and the General Hospital, Nottingham, each become entitled to £1,000. Miss Anne Wells, has bequeathed the sum of £100 to the Norwich Hospital. By the will of the late G. H. Lawrence, Esq., the Liverpool Royal Infirmary, and the Blue Coat Hospital, each receive £100. The Bradford Royal Infirmary is entitled to £100 bequest, from the late W. Rand, Esq., of Bradford.

The Ulverston Guardians and the Poor Law Board.

Some few weeks since, a series of charges were preferred by the medical officer, Mr. Cranke, against the master and matron of the workhouse, for wilful interference with his duties, neglect of instructions, and tampering with the diet of his patients. An investigation was also made into the conduct of the schoolmaster, and although no specific charge was made against him, the Inspectors, nevertheless, considered the evidence sufficient to call for his resignation, as well as that of the master and matron. The enquiry occupied the attention of the Poor Law Inspectors for the space of three days; and when the decision of the Board was communicated to the Guardians, a meeting was convened on Thursday last, at which it was determined to set aside the resolution of the Poor Law Board, and to memorialise the Right Hon. G. J. Goschen, to withdraw the same. Whether this petition will be successful, remains to be seen, but we do protest against the unwarranted assumption of the Board of Guardians, that after a patient hearing, before two able officers of the Crown, they should thus seek to set aside a decision, which was founded alike upon evidence and justice. True, one of the guardians admitted that, if the committee had had their way, the matter would never have gone before the Poor Law Board; but the medical officer considered it to be his duty to press the charges for an official enquiry, and the decision should, therefore, be respected.

Dr. Steele's annual report of Guy's Hospital has lately appeared, and is full of interesting statistics.

Mr. W. E. C. Nourse, F.R.C.S., has been appointed Surgeon to the Brighton Hospital for Sick Children.

The order of the Iron Crown of Austria, has been conferred by the Emperor, upon Dr. Petermann, for his services to the cause of science.

The "Sharpey Memorial" is assuming a solid appearance, and the committee hope to found something more than a scholarship.

It is presumed the appointment of Dr. Smart to the rank of Inspector-General of Hospitals and Fleets will necessitate his retirement for the present upon half-pay.

The vacancy in the Greenwich Hospital Pension, created by the death of Mr. James Hall, M.R.C.S., has been awarded to Deputy Inspector-General of Hospitals Charles H. Fuller. The pension is worth £50 per annum.

At the late meeting of the Parliamentary Committee of the British Medical Association, on the motion of Dr. O'Bryen and Dr. Ramsay, the Draft Medical Acts Amendment Bill was referred to the sub-committee, with power, if necessary, to confer with the General Medical Council and the Committee of Council.

The statement of a contemporary, that the appointment of Dr. Armstrong as Director-General of the Medical Department is but for a period of five years is incorrect. The duration of the office was not named, nor any condition of the kind imposed when the appointment was so deservedly given to Dr. Armstrong.

Mr. Shaw having resigned his surgeoncy at Middlesex Hospital, Mr. Nunn, till now extra surgeon, takes his place. Mr. Hulke will most likely take Mr. Nunn's office. Mr. Tay, as we predicted, has gained the assistant-surgeoncy at the London Hospital. Mr. Paget resigns his lectureship on surgery at St. Bartholomew's. Mr. Holmes Coote and Mr. Savory will conduct the course conjointly. Mr. Pearse is a candidate for the assistant-surgeoncy at the Westminster, vacant by the lamented death of Mr. Bruce.

We understand that the committee of the Metropolitan Free Hospital have decided, by a case which was brought lately before them by Dr. Charles R. Drysdale, that ladies are not to be permitted to study medicine at that hospital. This is, we believe, the second time the case has been tried by our *confrère*. It seems that, if ladies desire to acquire any knowledge of their profession, they must make up their minds to have a hospital of their own. Probably the example of Miss Garrett may relume that enthusiasm for the career of medicine, which has recently been rather flickering than blazing, owing probably to the rejection of Mr. Mill by Westminster.

◆

SURGICAL SOCIETY OF IRELAND.

(Continued from page 336.)

cording to this method the anterior flap will be shorter by a fourth than Teale's, and there will be no posterior flap." As this proposal appeared to me to be based on sound surgical principles, I determined that I would give it a trial the first opportunity that occurred.

Shortly after this a patient, aged thirty-four years, whose occupation was that of a sailor, was admitted into the Richmond Hospital on account of very extensive lupoid ulceration of the right leg. It commenced about eight years ago, after a fall over a rope, against which the lower part of the leg struck, which he sustained while running along the deck of the vessel during a dark night. Shortly after this, ulceration appeared in the situation where the injury had been received, and commenced to spread extensively.

For some time after his admission into the Richmond Surgical Hospital the case was actively treated both locally and constitutionally, and very considerable improvement took place. So much so, that he was making arrangements to return home, when suddenly a sloughing process supervened, having many of the characters of hospital gangrene. This spread rapidly, engaging the dorsum of the foot, and laying bare the tendons, muscles, and arteries. From the latter, which became ulcerated and opened, very sharp hæmorrhage occurred, which was with much difficulty controlled; indeed, it was not satisfactorily arrested until I passed acupressure needles under the vessels, and made pressure on the arteries by passing loops of wire across the needles. The "third method of acupressure" was adopted, and proved in every respect perfectly satisfactory. As the disease spread close to the knee-joint, I did not think it advisable to amputate below the articulation, and I was also deterred from doing so from the fact of the disease attacking the stump, and I did not think either that I could get sufficient healthy integument to cover the broad cut surface of the tibia in front. Behind, I admit, I might possibly have obtained a sufficiency, but I was deterred from making the attempt by a very strong objection which I have to long posterior flaps taken from the calf of the leg. All things considered, I deemed it preferable to amputate above, but as near to the knee-joint as I could, and I have not, I must allow, been disappointed in the result, whether as regards situation of the amputation or the method adopted.

It is unnecessary to enter into any of the minute details, either as regards the operation or the subsequent progress of the case. The former was performed without any deviation from the proposed modification of Teale's amputation, and of the latter, one mishap has to be recorded (though, in truth, it might be adduced as an argument in favour of the operation to those who object to the modification on the grounds of there not being a sufficiency of flap), and that was, that four or five days after the operation a small portion of the anterior flap sloughed away; but, notwithstanding this, there appears to me to be an ample covering of soft parts on the face of the stump. Now, what are the objections which have been urged by surgeons against the modification?

They are six in number, and may be briefly enumerated as follows:—

1.—The cicatrix being too near the face of the stump.
2.—Tension of soft parts on the face of stump.
3.—Insufficiency of covering.
4.—That, owing to retraction of the tissues, the posterior surface of the bone projects, and is denuded of soft tissues.
5.—Liability of cicatrix to become adherent to the immediately subjacent bone.
6.—Increased risk of pyæmia.

As regards the first of these objections, I would remark that it appears to me that instead of the cicatrix being too near the face of the stump the chances are that, owing to the retraction of the posterior tissues it will be further away from the face of the stump than in the operation as originally suggested by Mr. Teale. When the posterior tissues are divided they immediately retract, and the retraction does not cease at the time of the operation, but continues during the process of healing,—a fact recorded long since by Alanson—and consequently the cicatrix is drawn high up on the posterior surface of the limb. So much, then, for the cicatrix being too near the face of the stump.

The second objection is the liability to tension of the soft parts on the face of stump. This, it has been said, exists in the case which you can presently have an opportunity of examining. It may, I confess, be thus to a certain extent; but I do not think that it will in any way interfere subsequently with the usefulness of the stump. As regards this point, too, it must be remembered that he had a certain loss of tissue from sloughing of the anterior edge of the flap. Had that not taken place there can be no doubt we should not have had the amount of tension, such as it is, which has been observed.

The result of my case shows that the third objection, viz., insufficiency of covering, is not a valid one.

The fourth objection is one which Mr. T. Pridgin Teale, the son of the originator of the rectangular flap operation, has made in a letter which he published in the *British Medical Journal* for Nov. 7, 1868. He observes, "if, however, the posterior tissues be divided opposite the point selected for sawing through the bone, they immediately retract to a point higher up, and thus have the posterior surface of the bone projecting and denuded of soft tissues." At first sight this appears a grave objection; but we need not fear this so much when we reflect "that," as Mr. Lister observes, "it fortunately happens that the bone lies forward among the muscles, so that even its posterior surface is considerably anterior in position to the longitudinal axis of the limb." The tendency is always for the bone to come forward; and if a proof of this were wanting, we have only to bear in mind the fact that in the cases where ulceration of the flap takes place, it is in the great majority of cases through the anterior and not through the posterior or lateral position of the stump that the bone protrudes.

Projection and denudation, therefore, of the bone posteriorly need not, I think, be apprehended.

The remaining objections to this modification, viz., the liability of the cicatrix to become adherent to the immediately subjacent bone, and the increased risk to pyæmia, made by a house-surgeon of Leeds, whose name escapes my memory, need not, obviously, be dwelt upon.

Such, then, are the advantages of this modification of Teale's amputation, the chief objections which have been raised against it, and the way in which it appears to me they may be best answered. Although I have performed the operation frequently on the dead subject, I have only performed it once on the living, and the result you will have an opportunity of judging for yourselves.

I should be sorry you should think that I advocate this operation in preference to all other methods of amputation of the thigh. This I do not wish to do. But I think the case is of considerable surgical importance, as it affords a proof of the unsoundness of many objections that have been raised against this modification, which, I am bound to say, I never should have been induced to test on the living subject had not the suggestion come from one who has given to this as well as to all other subjects connected with his profession an anxious as well as a wise consideration.

Mr. Croly said he had had the great advantage of learning the rectangular flap operation from Mr. Teale himself. He had also published in the *Quarterly Journal* a few years ago, a series of rectangular flap operations, and advocated that mode of proceeding very strongly. He had not in any case since, except in the middle of the leg, performed any other operation. The point now before the society was the modification of the operations suggested by the chairman. He did not believe there was so much difference between the extent of surfaces exposed in the rectangular and the circular operations. One objection to Teale's operation was the length of bone to be removed. In a machinery accident they were unable from obvious reasons, to take a long anterior flap and a short anterior one, without going higher up on the thigh than would be necessary by other methods; but in a case of disease in operating by the rectangular flap method, they could take a skin flap from below the patella, and they all knew that a skin flap was the best they could have. With regard to the modification suggested by the chairman, he had long ago expressed his opinion, and Dr. Geoghegan, one of his colleagues in the City of Dublin Hospital, agreed with him, that in future cases of amputation by Teale's method, they ought to shorten the long flap. The only difference which he could see between the stump exhibited by Mr. Stokes, and those which he had produced by Mr. Teales method, was that in the former, the cushion on the anterior part was not so moveable. One of the advantages of Teale's amputation was, that when the finger was placed on the stump there was a bursa, and they could move it about; while in Mr. Stoke's case there was more tension. It was when the patient began to walk about with an artificial limb, and the weight of the body came upon the end of the stump, that the usefulness of Teale's rectangular flap operation was more particularly observed. The modification which he (Mr. Croly) would adopt, was to shorten the anterior flap for an inch or two, but not to do away with the short flap altogether. With regard to mortality in Ireland, as far as he could ascertain, there had not been a single death from the rectangular flap operation, and not only that, but there had been no sloughing. Surgeons had sometimes been disappointed with the result of this operation, finding that the anterior portion sloughed. No doubt, what the chairman had suggested was a step in the right direction, but he would say that shortening the long flap and leaving the short one as it was, and so giving a flap movable on the stump, thereby preventing the tension that existed in this case, was the only modification that Teale's operation required.

Mr. Hamilton said they must give the stump exhibited by Mr. Stokes that evening credit for being a very good one. He thought too much importance was attached to the idea of pressure on the face of the bone; for after the operation, in his opinion, the pressure should be borne chiefly upon the circumference of the limb. He had performed Teale's operation three times, and he did not think he would ever perform it again, except under very special circumstances. No doubt the case did very well, but he did not see why they would not have done as well, had some of the older methods of operation for amputation of the thigh been adopted. He was much more in favour, especially near the knee, of the circular operation; and he saw a good many cases going about which were evidences of the good old surgery of Cusack, Abraham Colles, and Wilmot—the individuals having exceedingly useful stumps, after operation by the old circular method.

Mr. Collis said Mr. Hamilton had apparently overlooked the freedom from mortality that attended amputation by Teale's method, which alone was a reason for giving that method a further extended trial. Surgeons ought not to rush into a fashion of always performing Teale's operation, for there were some cases for which it was not suitable. He had no doubt there were cases in which the surgeon might be tempted to perform Teale's operation, where the cutting through the thigh might be avoided by an operation through the joint. He though if they were able to get a long skin flap from the front of the leg, they might be able to get a flap from the back, which would enable them to go through the joint. The leaving of the cartilages had been made an objection to amputation through the joint; but he had no hesitation in saying that cartilages were no obstacle whatever to union by primary intention. He had seen an amputation through the joint, where there was not a drop of matter, and the stump was perfect. He would therefore throw out the suggestion, that while they approved of Mr. Teale's operation and such modifications of it as the chairman had suggested, they must not allow their preference of Teale's method to blind them to the fact that there were other modes of operation which might be resorted to with advantage.

Mr. B. Wills Richardson observed that Mr. Stokes alluded, in his prefatory observations, to a name which, at a meeting of the Surgical Society of Ireland, deserved more than a mere passing notice, he (Mr. Richardson) meant that of Benjamin Bell, a member of this college, whose anterior flap operation above the knee differs so little from the thigh anterior flap operations recommended since his time, but associated with the names of other surgeons. He (Mr. Richardson) would read to the meeting Bell's description of his operation above the knee, and he had no doubt that the members would then recognize how closely he has been imitated by more modern surgeons. According to Bell, "the extreme point of the (anterior) flap should reach to the end of the limb, unless the integuments be in any part diseased, in which case it must terminate where the disease commences, and its base should be where the bone is to be sawn. This will determine the length of the flap; and we must be directed with respect to the breadth of it by the circumference of the limb; for the diameter of a circle being somewhat more than a third of its circumference, although a limb may not be exactly circular, yet by attention to this circumstance, we may ascertain with sufficient exactness the size of a flap for covering a stump. Thus, a flap of four inches and a quarter in length, will reach completely across a stump, whose circumference is twelve inches; but as some allowances must be made for the quantity of skin and muscles that may be saved on the opposite side of the limb, by cutting them in the manner we have directed, and drawing them up before sawing the bone, and as it is a point of importance to leave the limb as long as possible, instead of four inches and a quarter, a limit of this size where the first incision is managed in this manner, will not require a flap longer than three inches and a quarter, and so in proportion according to the size of the limb. The flap at its base should be as broad as the breadth of the limb will permit, and should be continued nearly, although not altogether, of the same breadth to within a little of its termination, then it should be rounded off, so as to correspond as exactly as may be with the figure of the sore on the back part of the limit. This being marked out, the surgeon standing on the outside of the limb should push a straight double-edged knife with a sharp point, to the depth of the bone, by entering the point of it at the outside of the base of the intended flap, and carrying the point close to the bone, should push it through the integuments at the mark on the opposite side. The edge of the knife must now be carried downwards, in such a direction as to form the flap, according to the figure marked out; and as it draws towards the end, the edge should be somewhat raised from the bone, so as to make the extremity of the flap thinner than the base, by which it will apply with more neatness to the surface of the sore. The flap being supported by an assistant, the integuments and muscles on the back part of the limb should, by one stroke of the knife, be cut down to the bone about an inch beneath where the bone is to be sawn; and the muscles being separated to this height from the bone with the point of the knife, the soft parts must all be supported with the leather retractor till the bone is sawn." It was unnecessary, Mr. R. further observed, to read the completing steps of the operation, his object being to remind the Society how closely Bell's anterior flap resembles that of Teale in being nearly rectangular. In his (Mr. R.'s) opinion, Bell's flap has an advantage over the rectangular one in being free from the angles—the angles of soft parts raised from underlying structures we know by experience being very liable to slough. In the dissection of the muscles from the bone before it is sawn, in Bell's operation, a modified short posterior flap is thereby formed, and thus the analogy between it and Teale's amputation is still more striking.

The Chairman observed that the modifications he had suggested was not of recent date. The first time he saw Teale's operation he thought there was an enormous amount of cutting, and mentioned the modification to the late Mr. Smyly, who agreed with him, but did not seem to take much interest in the subject. He then mentioned it to Mr. Ledwich, who performed the operation on the dead subject, and came to the conclusion that there was ample covering for the stump. In consequence of a recent paper by Dr. MacCormac, of Belfast, he wrote to that gentleman, who, in a letter which he had received that day, informed him that he had operated on the dead subject according to his (the Chairman's) suggestion, and found that the parts when brought together were all that could be desired in a stump. It was unexceptionable in form, there seemed to be ample covering, and it appeared to possess every advantage that could be claimed for Teale's operation. He (the Chairman) tried the operation on one occasion on the dead subject in the presence of Dr. Mapother, who was amply satisfied with the result. He had spoken to his friend, Mr. Stokes, on the subject, but the first thing he heard of this case was by a letter which he received from Mr. Stokes on the 9th of December last, stating that he had performed the operation with a result fully bearing out what Dr. MacCormac had stated.

Dr. Mapother said he had the pleasure of seeing Mr. Wharton perform the operation on the dead subject, and it seemed to him to be a very beautiful one, and he fully agreed with him in the advisability of trying it whenever an opportunity arose.

Mr. Stokes, in reply, said the two advantages of the modification suggested by Mr. Wharton appeared to be, that there was a diminution in the extent of cut surface and a decided saving of bone. Mr. Croly did not think there was so very much cut surface in Teale's operation, but in the modification suggested by the Chairman there was less; for in the latter there was but one flap, while in the former case there were two. With regard to the tension of which Mr. Croly had spoken, he agreed with Mr. Hamilton that tension on the face of the stump was not of much importance, because the pressure should be made on the circumference of the limb. It should be borne in mind that, although there might be a certain amount of tension here, it arose altogether from the partial sloughing of the anterior flap. Mr. Croly said that no death had occurred in Ireland after Teale's operation. He was not altogether correct, for he (Mr. Stokes) was the unfortunate exception. It was the second operation of the thigh he had performed, and he adopted Mr. Teale's method; the patient got on very well for the first fortnight, but gradually sank and died with symptoms of pyæmia. They should congratulate themselves on this, that, notwithstanding the objections Mr. Croly had made, he modified them by saying that the Chairman's suggested modification of Teale's operation was a step in the right direction. There was no doubt that Teale's operation was very similar to Bell's.

The Society then adjourned.

Correspondence.

NITROUS OXIDE IN DENTAL SURGERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I had written a letter in reply to my respected and venerable friend, Mr. W. S. Whatford, when I discovered one in your columns from Mr. Braine, who must be regarded as an authority in this matter and whose, reply is to the point, and renders my own quite unnecessary; I will, however, trouble you with a modification of what I had written, as the subject is full of interest to those who are anxiously looking for a safe anæsthetic.

Without referring to the great success of this agent in America, where upwards of 200,000 cases are reported in five years with but one fatal result, and that in a phthisical patient who ought not to have inhaled it, I cannot do better than refer objectors to the report of the scientific committee, appointed by the Odontological Society to consider this question, which was published in the Society's "Transactions" for December last. The very favourable conclusions of the committee as to the superiority of this anæsthetic in dental surgery were founded on 2,431 recorded cases.

My own experience only extends to about 200 cases (and I think an administrator should see something like 1,000 cases before he writes in very positive terms), but I am able to endorse Mr. Braine's remarks, and I would direct attention to that part of his letter where he refers to unpleasant dreams, arising from the unequal pressure of the gasometer. Mr. Whatford alludes to cases with "very alarming symptoms," but did not inform your readers what those symptoms were; if by that he means a cyanosed appearance of the patient, I admit that to those accustomed only to chloroform administration such symptoms are alarming, but it is a very striking fact in these cases, that as soon as the inhaler is removed, the colour returns instantly with the re-organization of the blood. Some persons are alarmed at the snoring which sometimes takes place during the inhalation, and call it stertor, a dangerous condition, but the sound heard no doubt, arises from the vibration of the relaxed palatal muscles and may be legitimately called snoring.

As to the "kicking and screaming," it need scarcely be remarked that in hysterical patients these symptoms are easily produced with any anæsthetic and with nitrous oxide especially, if the administration is loosely or carelessly conducted. It is important that the respiratory organs should have full play, and that tight stays, or fastenings round the waist and throat, should be strictly forbidden. In cases where I suspect hysteria, I have learnt not to be afraid of giving the gas; my aim is to produce a profound anæsthesia; I am supported in this by the practice of eminent administrators.

The patient's recovery is much more pleasant when silence is strictly observed during the exhibition of the gas. The sense of hearing is so acute under its influence that any talking disturbs.

The most unpleasant cases I have had were among the first 50—owing no doubt to timidity and want of experience, and I therefore infer from this that Mr. Whatford's cases will improve as he advances in his investigation.

I have found that the greatest objectors are those who, either have not seen the gas given, or have witnessed it carelessly administered by inexperienced persons.

That we shall hear of accidents with so subtle an agent is, I think, probable; even careful and skilled practitioners will have their serious cases which time alone will bring to light; but what the public have most to dread is, I think, an unskilful administrator.

If some eminent physiologist would investigate this subject closely, and publish his results, it would be of much service in the meantime, practical hints from practical men would be helpful. It is with the hope that some simple hint or two might be usefulto some of your readers, that I have ventured to intrude upon your valuable space.

I am, Sir, yours truly,

J. Dennant, L.D.S., R.C.S.,
Dental Surgeon to the Brighton Hospital
for Sick Children.

Medical News.

Unwholesome Food.—Dr. Ballard, the Medical Officer of Health for Islington, last week obtained a magistrate's order for the destruction of a large quantity of cod-fish which had been seized as unfit forfood. The fish had been purchased in Billingsgate market as fresh, and when it was got home it was found to be quite unfit for food. Under those circumstances the fish was brought to the vestry for condemnation, and a certificate was given to the person who brought the fish that it had been condemned, so that the buyer might get his money from the salesman. Dr. Ballard said that in every case but one those who had received a certificate from the parish authorities had recovered his money. The fish in question was so putrid that it was quite unfit to be brought into court

Deaths in the Metropolis.—In the first 13 weeks of the year 1869, the first quarter of the year, there have been 20,088 deaths in the metropolitan district a number about 1,200 less than the average for this, the most fatal, quarter of the year, allowing for increase of population. In almost every week of the quarter the mortality has been below the average. 9,228 of the deaths were of persons under 20 years of age, 2,800 of persons 20-40; 3,455 of persons 40-60; 4,605 of persons 60 and upwards. There were in the 13 weeks 69 deaths in the metropolitan district from small-pox, 300 from measles, 648 from scarlet fever, 81 from diphtheria, 886 from whooping cough, 266 from typhus fever, 331 from enteric fever, 189 from simple continued fever, 177 from diarrhœa, 2,294 from phthisis, 2,993 from bronchitis, 1,231 from pneumonia, 1,010 from heart disease.

The Royal Hospital for Incurables.—In 1854 Dr. Andrew Reed founded this institution to afford a home for those who, discharged uncured, needed an asylum; and, secondly to give a pension of 10*l.* a year to those who, having a home were still in need of partial relief. The building belonging to the institution is situated at Putney, and contains 120 inmates, while the pension list amounts to upwards of 4,000*l.* a year. The 15th anniversary of the charity was celebrated last week. In the course of his address the noble chairman, Viscount Sydney, dwelt upon the special claims which the charity had upon the public. He observed that it did not come into competition with any other hospital, and it was only when the physician intimated that art had done her utmost that the institution stepped in and gave the benefits it was peculiarly designed to confer. Mr. Andrew, the secretary, in announcing the amount of the subscriptions to be 2,500*l.*, reminded the subscribers that, in consequence of the building of the new wing to the hospital, a debt of some 7,000*l.*, had been contracted, which it was earnestly hoped the friends of the institution would speedily discharge.

We have been requested to announce in consequence of the domestic bereavement sustained by his Royal Highness the Prince Christian, the annual festival of University College Hospital which had been advertised for the 20th inst, has been unavoidably postponed to the 23rd of June, when his Royal Highness has graciously consented to preside.

A Committee of the Medical Society of London, has Drawn up the Following Questions for Circulation.—"1. Do you consider the formation of biliary concretions to be influenced in any way by age, sex, hereditary tendency, mental conditions, food, climate and the like? 2. Is the natural formation of a biliary concretion to be detected by the manifestation of any peculiar symptoms of dyspepsia? 3. Do you consider it possible to determine symptoms of the presence of biliary concretions in the gall bladder, or the ducts of the liver? 4. Can you narrate any cases of (*a*) biliary fistula, (*b*) communication between the biliary passages and other internal organs? 5. What plan of treatment have you found efficacious for the general dyscrasia, and the relief of pain during the passage of biliary concretions?

Prudential Assurance Company.—We do not know that there is any surer investment for the family of a prudent man, than that of a well managed Life Assurance Company, whether as a shareholder or assurer. The former it is true may sometimes find himself unfortunately allied to an office that is a perpetual source of anxiety to him, but the latter is always secure if the business is only conducted with ordinary care, every policy posessing a distinct value which can always be transferred from one company to another, for the protection and convenience of the assured. That the Prudential is carefully managed we think will be evident from the report which appears in another column and from which we extract the following figures.—The premium income at the close of the year amounted to £220,978 after making allowance for all policies lapsed or surrendered, the assurance fund amounted to £241,301 against £172,959 at the close of 1867, being an increase of £68,341; the new premium income for the year ending 31st December 1868 amounted to £87,749, the corresponding amount for 1867 being £54,819.

City Gas.—Dr. Letheby, the Chief Gas Examiner to the Board of Trade, has, in accordance with the City of London Gas Act of last year, reported on the quality and purity of the gas supplied to the city during the last three months. The results of the examinations as to the illuminating power in sperm candles were as follows:—City of London Gaslight and Coke Company, *maximum* 16·27, *minimum* 14·03, and average 14·83; the Gaslight and Coke Company, *maximum* 16·28 *minimum* 14·38, and average 15·26; Great Central Gas Consumers' Company, *maximum* 16·85, *minimum* 14·26 and average 14·99. The examinations were made three times daily, at intervals between the hours of 5 p.m. and 10 p.m. He also reports that ammonia has constantly been present in the gas of the Chartered and Great Central Companies, but that all the gas had been invariably free from sulphuretted hydrogen. The following were the amounts of sulphur in 100 cubic feet of gas:—City of London Company, 18·92, 11·70, and 15; Gaslight Company, 24·15, 15·75, and 19·49; and Great Central Company, 24, 7·03, and 12·28.

NOTICES TO CORRESPONDENTS.

SPECIAL NOTICE TO SUBSCRIBERS IN IRELAND.

The Subscribers are respectfully informed that the offices of this Journal have been removed to Moffat and Company, 6 D'Olier street, Dublin, to whom all business letters should henceforth be addressed. Editorial communications should be sent to Dr. Jacob, 23 Ely place.

NITROUS OXIDE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In my last note to you, "On the Administration of Nitrous Oxide in Dental Operations," by a printer's error you make me say that I should be sorry to have a tooth removed *with* being previously put under the influence of the gas. What I really said was, that I would not have a tooth extracted *without* being under its influence. Trusting you will correct the mistake,

I am, faithfully yours,

F. Woodhouse Braine, F.R.C.S.

Mr. T. Dalston, Brough.—We shall be happy to accede to your request.

Dr. W. D. Moore.—Aneurism of the Aorta cured by Acetate of Lead, received with thanks.

Cantab.—The candidates intending to offer themselves for examination for medical and surgical degrees at the University Anatomical Schools are required to signify the same to the Regius Professor of Physic on or before the 17th of May, and to send at the same time their certificates. A fee of three guineas is paid to the professor by each candidate when his name is sent in for his first examination for the M.B. degree. The first and final examinations for the degree of M.B. will begin on Monday, the 31st of May, at nine a.m. The second examination for the M.D. degree and the examination for the degree of Master in Surgery will begin on Monday, the 7th of June, at nine a.m.

Dr. Lamprey, Portsmouth.—The three blocks received are in the hands of our engraver. Proofs shall be sent you shortly.

Mr. Crane.—A paragraph of the decision was in type for our last issue, but was crowded out at the last moment for want of space.

Dr. Madden.—Proof will be sent you this week.

Dr. Bean, Ashburton.—We will endeavour to procure and give you the desired information in our next.

A Graduate.—Dr. Richardson has been elected to the Assessorship of the University of St. Andrews by a majority of 60 votes.

◆

VACANCIES.

Member of Council, Royal College of Surgeons, Ireland.—Vacant by the death of Dr. Mackesy. Election, April 26th.

Newport Union, Achill District.—Medicall Officer. Salary, £80, exclusive of fees. See advertisement.

Newport Union, Ballycroy District.—See advertisement.

Charing Cross Hospital.—Surgeon to the Skin Department.

Carlow Union.—Medical Officer. Salary, £100, exclusive of fees. See advertisement.

New Ross Union.—Medical Officer. Salary, £70, exclusive of fees. See advertisement.

Ely Union.—Medical Officer. Salary, £45, with fees for Midwifery Cases, &c. Election, to-morrow (Thursday).

Wandsworth and Clapham Union.—Salary, £75, with Operation and Midwifery Fees. Election, to-morrow (Thursday).

◆

APPOINTMENTS.

Auchinleck, G., M.D., Staff Surgeon-Major, after 20 years' full pay service.

Abercromby Anderson, C., M.D., and W. R. E. Smart, C.B., M.D, were on Friday last promoted to the rank of Inspectors-General of Hospitals and Fleets.

Bangay, R., M.D., Surgeon to the Eastern Dispensary, Bath, vice W. Bush, M.R.C.S.E., resigned.

Dickson, Dr. J. T., Resident Medical Superintendent of St. Luke's Hospital for Lunatics, vice J. Ellis, M.D.

Falls, Dr. W., resident Surgeon-Apothecary to the Warrington Dispensary, vice Bagnall.

Gourley, S., M.D., Surgeon to the Hartlepool Hospital, vice G. Kirk, resigned.

Advertisements.

CORONERSHIP FOR WEST MIDDLESEX

THE QUEEN v. DIPLOCK.

THIS CASE has been EIGHT TIMES before the Judges of the Court of Queen's Bench, and the illegality of the votes recorded for Mr. Diplock has been substantially decided.

Dr. Hardwicke, in the full conviction that he had a majority of the freeholders in the Western Division of the County of Middlesex, was urged by his friends, as the most fitting candidate, to continue the contest till the end.

Dr. Hardwicke was returned by the legitimate votes of the freeholders, by a majority of two to one. By the illegal tender of votes by persons assuming to be freeholders on the ground that they possessed graves or were watermen, which votes were wrongfully recorded, and the legal votes were out-numbered, and Dr. Hardwicke's opponent was illegally returned as Coroner for the County.

The great expenses incurred by Dr. Hardwicke in his election has been upwards of £1,700. He is unprepared to continue the contest in the Court of Queen's Bench without further assistance, and the Committee appointed to secure his election have no hesitation in recommending to his friends of the Medical Profession, as well as those who are anxious to maintain the integrity of popular institutions and the purity of our electoral system.

Subscriptions to Dr. Hardwick's Election Fund are earnestly solicited, and will be received by the following gentlemen:—

Chairmen of Committee ... George Cooper, Esq., J.P., Brentford; Edwin Lankester, M.D., 23 Great Marlbro' street.
Treasurer ... W. G. Farnall, Esq., Isleworth.
Hon. Secs. ... Dr. Holt Dunn, Hereford road, Bayswater; G. Benson Baker, M.R.C.S., 42 Grove rd., St. Jn.'s wd.
Bankers ...... London and County Bank, and Branches.

CARMICHAEL SCHOOL OF MEDICINE,
NORTH BRUNSWICK STREET.

THE SUMMER SESSION will COMMENCE on MONDAY, APRIL 26, 1869.

Practical Chemistry	Dr. E. Davy	Tues., Thurs., Sat., 12 to 1 o'c.
Materia Medica	Dr. Fraser	Mon., Wed., Fri., 12 to 1 „
Medical Jurisprudence...	Dr. O'Reilly	Mon., Wed., Fri., 1 to 2 „
Botany	Dr. Campbell......	Tues., Thurs., Sat., 1 to 2 „

Carmichael Medals and Prizes will be awarded in each of the Summer Classes. For particulars apply to

Dr. CORLEY, Registrar, 14 Summer hill.

Address

OF THE

RIGHT HON. JOHN INGLIS, L.L.D., D.C.L.,

Lord Justice-General of Scotland,

DELIVERED ON HIS INSTALLATION AS CHANCELLOR OF THE UNIVERSITY OF EDINBURGH,

APRIL 21ST, 1869.

Theory of University Education.—I proceed at once to offer you some suggestions which may be available in carrying on that liberal and comprehensive course of improvement which has already done much to promote the usefulness and enhance the reputation of our University. The great principle which lies at the foundation of every sound theory of University education in this country is so obvious as almost to amount to a truism, and yet requires to be kept constantly present to the mind. It is, that the Professors are made for the students, and not the students for the Professors. Were we possessed of wealth sufficient for such an extension of the professoriate as would furnish a complete and effective body of teachers, and yet enable others to devote themselves more to the pursuit of scientific research, and the cultivation of the highest scholarship; it would indeed be well both for the University and for Scotland; and the day may not be so far distant but that some of our younger graduates and of our students may live to see an adequate portion of the rapidly accumulating wealth of Scotland applied to the noble purpose of securing not only the highest and best education for our youth, but places of literary leisure for our matured scholars and leaders of scientific inquiry. But we must deal with existing facts; and while we confess, with regret, that no such provisions form, for the present, any part of our academic system, we may yet console ourselves with the reflection that by perfecting and completing the teaching powers of our professoriate, we are doing good work in the meantime, and by gradually and certainly raising the standard of attainments among our students, and in the same proportion increasing the aggregate of scholarship and scientific acquirement, both in the University and in the country, are laying the surest foundation for that full recognition of the claims of learning which will in the end attract to the seats of our Universities all who are most renowned for their erudition, and who desire the repose of an academic life, with an assured competency, and the command of their own time for the further prosecution of their favourite studies.

The Professors.—In our day the Professors of our University must all devote themselves chiefly to practical teaching; and therefore the first and leading question will always be how to find the best Professors—that is, the Professors who will make the best students—who will impart the greatest amount of instruction of the best quality, in the most acceptable and useful form—guiding and counselling the clever, the ardent, and the ambitious student, exciting and encouraging the timid and the backward. The first pre-requisite to the constitution of such a body of Professors as will most efficiently discharge these duties plainly is that the patronage of the chairs should be administered with a single view to fill every vacancy by the election of the best qualified person that can be procured. But to this end, in what hands ought academical patronage to be placed? This is the subject of an old controversy; but it is a theme of paramount importance to the well-being of our University, the consideration of which, in a calm and candid spirit, seems to me neither inopportune nor unappropriate to this occasion.

University Patronage.—That University patronage is a trust and not a right—a trust for the promotion of a great public object, and not in any degree for the benefit of individuals or of classes; and, consequently, that those who rightly administer the trust cannot derive from it any selfish advantage or even any personal gratification, except what may arise from the consciousness of pure, intelligent, and successful discharge of duty—are propositions which, stated in the abstract, cannot be seriously impugned. The burden which such a trustee undertakes is a high responsibility; his reward the approval of his own conscience. There are three great qualifications for the exercise of patronage—honesty, firmness, and the capacity of making a discriminating choice; and it will be found that the men who possess these gifts, and who know best how indispensable is their use in the administration of such a trust, are, generally speaking, the most apt to shrink from undertaking its duties. It is no easy task, at least for most men, sternly to disregard the claims of kindred, the appeals of friendship, the pressure of influence, to cast aside political and politico-religious prejudices and sympathies, to wade, it may be, through a morass of faithless and verbose testimonials in the almost vain hope of gathering a few modest blossoms of truth, to exhaust all other available and trustworthy materials for forming a sound judgment, and at last to address one's self to the task of selection with a single eye to the fitness of the person selected for the special office to which he is to be appointed. And yet such are the qualities, and such the amount of honest labour, indispensable to the right administration of University patronage.

The Distinction of Appointments.—How intimately the prosperity and reputation of a University are dependent on an honourable and wise administration of patronage may be further illustrated by the consideration that much of the dignity and repute of an office arises, in the estimation of scholars and gentleman, from the high character of those who have the power of appointment. To be selected, out of a large number of men recommended by their proved abilities and great attainments, as the one person best qualified for a Professor's chair, is a gratifying distinction, and an object of honourable ambition, provided the choice be made by persons whose character and qualifications afford a guarantee that it is a just, a pure, and a discriminating choice. But reverse these conditions, and the value of the distinction is lost. The emoluments and the duties of the office may continue the same; but its attractiveness will be sadly impaired in the eyes of those who would fill it with the greatest advantage to the University. The more honourable and worthy the patron, the more honourable and more honoured will the office always be.

Result of Bad Appointments.—On the other hand, it is difficult to exaggerate the evil effects of even one or two bad to indifferent appointments. For such misfortunes are apt or repeat themselves, and that from two causes—the University injured and waning in its reputation, will gradually fail to attract men of the best stamp as candidates; and the patron, will become by habit familiarised and satisfied with mediocrity.

Plurality of Patrons.—I do not propose to detain you by any detailed exposition of the various reasons assigned by Sir William Hamilton—in which, however, I entirely agree—for preferring a small plurality of patrons to either an individual or a numerous body, and for condemning the practice of vesting the appointment to chairs in the hands of the existing body of Professors, The Universities' Act of 1858, by transferring the patronage previously administered by the Senate to the University Court in all the Scottish Universities except Edinburgh, came very near—as near, perhaps, as was practicable—to the constitution of the small board projected by Sir William Hamilton, which should combine the exercise of patronage with a direct influence and control in the administration of University affairs. Since the new Courts entered upon their functions, nine appointments have been made by them—four in St. Andrews, four in Glasgow, and one in Aberdeen—and I believe it will be generally conceded that, so far as experience goes, the change has operated beneficially.

Objections to Crown Patronage.—Of that large portion of University Patronage which is vested in the Crown, and of its exercise by the Secretary of State for the time, it would be unbecoming to speak otherwise than with caution and respect. But as I entertain an opinion on the expediency of the existing arrangements, I do not see why I should withhold the expression of it from you. I think there are cogent reasons for objecting to the Crown, or, in other words, to the Government of the day, as the depositary of University patronage, at least to so large an extent as at present. It is impossible that in this or any other country similiarly situated, where the existence of opposing political parties affords one of the practical securities for the maintenance of free institutions and of personal and politicial liberty, patronage vested in the Crown should be exercised independent of political considerations or of the political tendencies of candidates for office. There are, no doubt, important exceptions; but I fear it is vain to attempt to classify professorships as falling within the exceptions and not within the rule. If, then, these appointments are influenced by political considerations at all, I conceive that an element is introduced which is entirely alien and irrelevant in the inquiry. Who will make the best Professor, in the department either of classical leasning, of mental philosophy, or of physicial science, and, still more, in the faculties of divinity, law, and medicine? The consequence is, that many men of acknowledged distinction in literature and science, who have no natural inclination to mingle in political strife, or to proclaim themselves the disciples of any political leader, are seduced from their more congenial and more useful occupations and studies, and taught to rely, not on their own merits as scholars or philosophers and teachers of others, but on their connection with one or other of the political parties in the country. This creates a relation between the patron and the class from whom he is to select, which impairs if it does not destroy that freedom and purity and highness of purpose which, I have said is, indispensible to the right administration of University patronage. Though a minister be animated by the most honourable desire to discharge this duty aright, he has neither the time nor the opportunity to make himself master of the subject; therefore, he must either rely on his own imperfect information, or he must trust to testimonials, or, lastly, he must take advice from better-informed persons. Practically, the last course is the one which will be followed, as being the best attainable. But this involves a delegation of judgment to persons of local information or special means of knowledge, and thus the choice comes in the end to depend on the suggestions of persons who, being exempt from the influence of public opinion and sensible of no direct responsibility are liable, unconsciously to themselves, to be swayed by motives which, in the public and direct exercise of patronage, the very same persons would entirely discard; while the minister who is directly responsible loses to a great extent his sense of responsibility and contents himself with the reflection that he has taken the best advice he could command.

Restriction of Crown Patronage.—Notwithstanding these disadvantages I am bound to confess that there are some compensating advantages (chiefly, perhaps, of a material kind, but not on that account to be despised or overlooked) in maintaining the intimate connection between the University and the Government which the Crown patronage of professorships, perhaps, as much as anything else is calculated to secure. It would, therefore, be a dangerous experiment, even if it were practicable, to abolish the whole of the Crown patronage and transfer it to the University Court or any other body; but it may at least be fairly asked, whether the amount of such patronage in the hands of the Crown be not excessive? For if this question be satisfactorily answered in the affirmative, though it may not lead to a diminution of the present amount, it may tend to prevent its increase in the event of the institution of new chairs.

Board for Administering University Patronage.—Now it appears to me that, in addition to the selection of well-qualified persons to constitute a board for administering University patronage, no better incentive could be found to a zealous and painstaking exercise of this important function than a generous emulation and rivalry, not among the Universities merely, but among the boards who, in the different Universities, are charged with the appointment of Professors. But, unless there be a separate board or set of patrons for each University, if the same individuals or bodies of men are entrusted with the patronage of more Universities than one, this wholesome rivalry is destroyed. The Crown patronage is obviously liable to this objection, as long as it continues so extensive as it is at present, and the objection will be aggravated by any future addition. For there cannot be the same zeal and anxiety to procure the very best man for a vacant chair, where the spirit of rivalry is entirely wanting, and the patron may be called on within a few weeks or a few years to fill up a chair in another University devoted to the teaching of the same science or branch of learning,

Our National University System.—The Scottish Universities are, and ever have been, teaching bodies. In conformity with the true theory of a University, and with all the ancient models, we hold it to be the condition of our right to confer Degrees that we should furnish a full course of instruction in every Faculty in which such honours are bestowed. And this teaching is the public and primary function of the University itself through its Professors, never delegated either to separate or affiliated colleges, or even to private teachers within the University, though private tuition is recognized as an important useful auxiliary. It follows that one of the great distinctive features of our system is the Professoriate—an active, efficient, and, so far as our resources permit, a complete, Professoriate. Again, the Scottish Universities have, without interruption in the course of their history, opened their gates freely to students of all classes and creeds and countries without distinction, the one qualification for admission being a healthy thirst for learning. Nor has this large and comprehensive invitation to all who desire the blessings of the highest education been coupled with any serious condition of a pecuniary nature. On the contrary, these advantages have always with us been attainable, not by the more wealthy classes of society only, but by the great bulk of the middle classes also; the consequence of which has been the formation of a body of students of a singularly manly and independent spirit; early trained, many of them, in the school of adversity, or, at least, of poverty and thrift, unsparing in their assiduity to profit to the utmost by that University career which has been procured for them, it may be with difficulty and sacrifice, and bearing with them out into the world all the natural fruits of these academical experiences—a stout heart and a well trained mind, with such stores of knowledge as form the best foundation for the larger, more extensive, and more varied education which is the proper business of the whole after life. No proposal of change can be listened to which shall shut out this body of students, or any part of them, from the University. We cannot spare such students as these. They are the very heart's blood of our nation, the men who have carried the name of Scotland and Scottish education to the uttermost parts of the earth; who are everywhere known and recognized as true representative Scotchmen—brave and self-reliant, acutely observant and yet deliberate, upright, energetic, and constant. To the production of this national character, probably nothing in the University system has contributed more than the catholic tone and spirit of our teaching. Some philosophers of the present day may perhaps look back with a feeling of pity allied to contempt to the days when our Professors were all nominally of one Church and one creed. But surely, even in those days we were in the enjoyment of great freedom of thought. Could the Scottish school of mental philosophy have ever been founded, or could it have attained its great eminence, if there had not been scope for the unfettered expression of speculative opinion? The test which was at one time imposed as a condition of the induction of Professors, was abolished by a statute which was carried through Parliament by our learned Rector, much to his honour; for the test was an anachronism. It was imposed at the Revolution, and renewed at the Union, for a great political object—the security of the Protestant religion. The occasion of the enactment was gone, and it was fitting that the enactment should itself also disappear from the statute-book. But though I approve of the removal of an invidious and useless statute, I cannot admit that the Professors who, before that time, carried on the teaching business of our Universities, either those who have since departed or those who still survive, were, or are, in any respect inferior to the younger men we see around us adorning and illustrating the various departments of learning which they teach. The instruction of twenty, thirty, or forty years ago, not to speak of earlier periods in the history of the University, was as liberal, as catholic, and as well adapted to attract students of all classes, and from all places, as it is at present, saving the advance which the world has since made in physical science, and in every other department of learning.

English and Scotch University Systems.—These peculiarities of our University system are well understood among ourselves and within Scotland. But much misapprehension has prevailed elsewhere, both about what we profess and what we achieve. When, fifteen or twenty years ago, the first serious attack was made on the two great Universities of England, and some rather unfavourable points of contrast were suggested between those magnificent foundations and our poor establishments in the north, a stout champion of the old Oxford and Cambridge school thus expressed himself:—"The Scotch Universities, are, indeed, institutions for all classes; they give a professional education to the medical man, and the curtailed general education to the tradesman. But Scotland is not on this account better off but worse off than England. . . . We have Scotch University education in our grammar schools and our medical schools, and we have also what Scotland has not, that which is called University education." A great deal of the truth or falsehood of a statement depends on the precise sense in which terms are used. In the English sense the English had, at the time of which I am speaking, a University education which we had not. But the true question was, Whether the education the English youth received at Oxford or Cambridge was, upon the whole, more worthy of the name of University education than that which was to be obtained at a Scottish University? The writer whom I have quoted seems to revel in the idea of the venerable English Universities rejecting professional studies and instruction as vulgar and grovelling. These Universities, according to him, had practically abolished all teaching in two if not three of the faculties Law, Physic, and Divinity—and devoted themselves exclusively to the Faculty of Arts. Such, too, was the conception that Professor Huber, of Marburg formed of the English Universities of that time, when he represented them as charged with the duty and vocation, not to form divines, jurists, and physicians, but "gentlemen," whom he describes as "a necessary and honourable element in the national existence." While the men of the English Universities were imbued with such ideas, it was no wonder that they should misunderstand our position. While they thought themselves entitled to confer degrees in law and medicine, without giving any efficient instruction in these sciences, though they had foundations and professorships in both, they might naturally believe that we were throwing away our time in educating men to professions. But now that a better spirit prevails, and the old Universities of England have become alive to the larger and more important duties that belong to them as national institutions—now that they are endeavouring to restore the just influence and action of the University as the proper teaching body, and to render the professoriate efficient for its original and proper purpose—they may be expected to have more sympathy with what we have been doing for centuries, and to acquire a more accurate knowledge of what we accomplish with our slender means. A desire of better acquaintance with us will also be enhanced by the conviction now spreading among them, that, even in general education, in the amount of instruction necessary to the attainment of an ordinary Degree in Arts, the standard of qualification is higher with us than with them. This important fact was confidently stated by my lamented friend the late Principal Forbes, of St Andrews, in 1861, when, as a Professor of this University, he was addressing such a body of young graduates as I am happy now to see before me:—"We know (he says) and have long known that the honours of a degree, such as you now bear, and such as your predecessors have in smaller numbers for many years borne before you, are only to be obtained by a struggle more varied, arduous, and prolonged than that which is required for the ordinary degrees of Oxford and Cambridge, which yet practically bestow a passport to most professional and official dignities. This important fact is only now becoming apparent to many educated persons at home. It is, then, hardly surprising that the knowledge of it has not yet penetrated to a distance." No one will charge a man so scrupulously honourable, and so strict an investigator of truth, as Principal Forbes, with any tendency to exaggeration or loose statement; and therefore his authority standing alone would carry with it the greatest weight. But he lived to see his statement confirmed by the opinions of unprejudiced and highly qualified judges, and nowhere more unreservedly than in the report recently presented to the English Schools Enquiry Commission by a very competent judge (Mr. Fearon), who says:—"The Scotch 'pass' Degree in Arts is, at least in two of the Universities (Edinburgh and Aberdeen), one which implies a much more real amount of reading and thought than the Oxford and Cambridge pass; and this not purely on account of the nature and number of the subjects prescribed by the course, but still more on account of the difference in habits and character between the Scotch and English students."

Average and Individual Scholarship.—But let us not attach too much importance to such admissions or testimonies. Above all, let us avoid that complacent self-satisfaction which would lead us to believe, or lead the world outside to think that we believe, that there is not before us a serious struggle which it will require all our energies to sustain. We must not rest satisfied with sending out our graduates in arts no better furnished than to compete successfully with the passmen of Oxford and Cambridge; for we must remember that, while we thus beat them upon the average, we have not yet succeeded in producing scholars of such accomplishments as those who carry away the highest honours of these Universities, and that much is in the course of being done, in an enlightened spirit, to improve their course of study preparatory to graduation, as well as largely to extend the area of English University teaching, both as regards the classes of society from whom their students are drawn and the subjects and departments of instruction.

The Honour of the University.—We shall always have powerful and worthy rivals both at home and abroad. We have also watchful critics, who will be satisfied with nothing short of constant progress and expansion. But, what is better than all, we have within our own walls an ardent and ever-growing spirit of jealousy for the honour of the University, which regards increasing activity and advance as the essential condition and proof of academic vitality. It is no part of the duty of those who hold any share in the government of the University to repress (even if they could) such honourable aspirations. They are the wholesome fruits of that change in the constitution of our Universities which gave a collective existence and privileges to the great body of the graduates. Attached to the University by closer ties than formerly, the members of the General Council feel a deep and personal interest in its welfare ; and the very fact of their not being directly engaged in the government of the University makes their opinions the more valuable, because they are removed from the immediate influence of academic conventionalities. But even those who contemplate with unmixed satisfaction a constantly progressive career of University reform, may accept my friendly words of warning, not to dissuade from immediate action, but rather to counsel a more close attention to those fundamental principles of our system, to which, in times past, Scotland has owed all the higher culture she possessed. Let us build on the old foundations, whose stability has been well tried, and if we extend our lines, and add to the ancient structure, let us at least not depart far from the original style, lest in the end we find ourselves, as the result of our labours, in possession of nothing better than a tasteless and incongruous pile, without unity or cohesion.

Foundation on Continental Models.—The architecture of Scotland is chiefly of foreign origin. But the rich turreted château and the church of flamboyant Gothic, when transported from France to our own more rugged shores and sterile moorlands, adapted themselves, under the hands of our ancestors, to the necessities of their new position, and underwent a series of almost imperceptible, but useful and inevitable changes, which suited them better to the available materials, to the climate, and to the tastes and habits and wants of the people of Scotland. So it was with our Universities. Founded on continental models, they have yet grown to be essentially distinct, not only from the parent institutions, but from all Universities of modern times. They have become Scottish and national. Possibly in some things they may have degenerated even from what Scottish Universities were ; and if it be so, no task can be more agreeable than that of restoration. But the work must be done by a careful and loving, as well as a skilled hand, guided by a discriminating knowledge of those peculiarities which are essential characteristics, and on which the utility of the institution mainly depends.

Constitution and Practical Working of Other Universities.—From the ancient Universities of England we have not hitherto borrowed much ; nor, indeed, was it expedient or possible while the principles on which they were conducted were so repugnant to those on which our own system was founded. But we can never forget that to them we owe some of the most distinguished men and most successful teachers that have ever occupied our chairs, and that the very dissimilarity of their training and of their feelings and habits of thought to those of our native professors has been an element of much practical utility, tending by friendly conflict to enlarge and liberalise the opinions, and to stimulate and guide the energies of both the one class and the other. From Oxford and Cambridge, too, we have borrowed the idea of providing rewards for high attainments among our graduates, not only by the system of class honours in the different departments of classical literature, mental philosophy, mathematics, and natural science, but also by the endowment of scholarships, which serve the same purpose with the fellowships of England, by holding out substantial inducements to the cultivation of more advanced learning, and affording to those who obtain them the means of prosecuting their studies after their university education has formally come to an end. The benevolence of our ancestors was for the most part exhibited in the foundation of bursaries, to enable young men to obtain a university education who could not otherwise have afforded it. These foundations have been productive of much good in times past, and within moderate limits they are calculated still to be beneficial. But there is, I believe, little difference of opinion now among those qualified to judge, that in some of the Scottish Universities at least they had become too numerous, and were in their excess productive of no good, or even positively mischievous. I am happy to think that the views propounded and the example set by the Universities' Commissioners appointed in 1858 have been received with favour, and have led, among other useful results, to the formation of an association for the better endowment of the University of Edinburgh, which proposes as its first object the foundation of additional scholarships open to competition by all graduates in arts. The success hitherto achieved by this Association, though it may not satisfy the sanguine expectations of some of its supporters, seems to me to offer encouraging promise for the future.

Social or Gregarious Study.—The most essential, probably, of all the distinctions between the English and Scottish university systems is, that in the former the undergraduates have hitherto had access to the University only through the medium of the colleges they have received their whole education and training, with slight exceptions. I need not disclaim any intention of recommending, even if it were practicable, an adoption of the English system in this respect. But while we are here, I presume, all agree that the delegation by the University to colleges of its own proper function of teaching is a reprehensible and inexpedient innovation on the ancient and true theory of university work, it may be worthy of consideration whether some benefits of English college life may not be attained without its drawbacks. A number of students living together under one superintendence, associated, not merely in their studies, but in their social hours and amusements, contribute largely and usefully to educate one another. If the head of the establishment be suited to his place, the tone of the society will be high both morally and intellectually, and the life will be cheerful and happy. The last is of the highest importance ; for the natural condition of the youthful mind is sprightly and impulsive, and whatever tends to unnecessary depression or sombre thought will impair its elasticity and vigour. Students placed in such cirtumstances as I have supposed will, generally speaking, be preserved not only from demoralising associations, but from debasing and vulgarising influences. The solitary student, if he be true to himself and firm of purpose, and particularly if his comparative poverty place him beyond the reach of strong temptation, may secure more hours for study, and accomplish a greater amount of intellectual work. But even in his case it may be doubted whether the gain is not purchased at too high a cost, and whether the training of the moral and social man is not too much subordinated to intellectual culture and attainments. The great majority of students, however, are not of the temper and disposition supposed, but, on the contrary, both desire and need variety and relaxation. To such men in early youth, when the character is in process of formation, the pleasures and the vices of a large city are perils and snares—not to the wealthy among them only, or to those who have money enough though to purchase pleasures that combine with their allurements something of a refining influence, but still more to those who, in the pursuit of pleasure, are constrained by their scanty means to rest content with what is coarser and more ignoble. It may be objected that the social or gregarious students' life will be found too expensive for many who come to the University. I do not believe the objection to be well founded in fact. A common table and sleeping accommodation for twenty or thirty students does not imply that they are to indulge in luxuries which, if they lived separately, they could not command ; while all experience of analogous cases leads one to conclude that, *cæteris paribus*, such accommodation can be provided more economically and of better quality for a large number than for one, two, or three. But even were it otherwise—were it true that this common or social life is not attainable by all—surely that is no reason why, if it be a good in itself, it should be denied to all. Entertaining these views, and being firmly persuaded of their general soundness, I have observed with pleasure the success of such an institution in St. Andrews, and with pain and disappointment the apparent abandonment of all attempts to follow the good example here. But I still hope that, ere long, reflection and experience will induce a revival of the project, which, even as a commercial enterprise, might, I am satisfied, be conducted to satisfactory results.

The German Universities.—The German Universities, much more than the English, have been suggested as models for our imitation by some university reformers distinguished both by their ability and their enthusiasm. Nor is this suprising. The external aspect of those centres of learning in Germany is most imposing, whether as regards the number of their professors and other teachers, the amount and variety of the subjects of their prelections, or the reputation for scholarship which the professors enjoy among the civilised nations of Europe. [After describing the German system at some length, the Lord Justice-General proceeded] :—The result of this system is described by its admirers to be not only a professoriate of unrivalled learning and intellectual activity, but a body of students who, when they leave the University, are distinguished by attainments more extensive, varied, and useful than are to be acquired in any other school. It is a bright picture. But as we gaze, some dark shadows flit across it. The German Universities, we are told by Germans themselves, have been hitherto engines in the hands of despotic Governments for the promotion of their selfish ends. Every academic interest, it is said, "like everything else, is merged in the State—that ideal of false worship tending to the dominion of egotism in its worst form." The concentration of learned men at the university seats, and their isolation from public and political life, which gives them leisure to produce learning so profound and universal, is a result obtained at the expense of the country, which is thus deprived of the active services of the best minds of the day, while the professors, as might be predicted, are, when called to take part in public or political life, found practically useless. To the Frankfort Parliament of 1848 no less than 118 professors were returned, and every one knows the result. It must seem at first sight a great advantage that, at the age of eighteen or nineteen, when he enters the University, the student's classical education is completed. But listen to the sequel as described by Professor Huber—"The preference might be well given on our side, if we were to take it for granted that upon this foundation we erected a proportionate structure of learning, or at least preserved the foundation itself. That this, however, is but little the case—that young men seldom keep up, while studying in other professions, the general cultivation bestowed or forced upon them in rich and over-rich abundance at school, none will deny but those who (knowingly or unknowingly) help to weave that great web of lies which envelopes our much-praised civilisation." When we read a general syllabus of the lectures delivered in one year in a German University, we are dazzled and almost blinded by the splendid variety and apparently unlimited extent. But here again Professor Huber dispels the illusion: "If we judge of this part of our public education by our pompous pretensions, by the signboards of our gymnasia, by the praises of modern Liberalism, the jargon of speculation, and the insipid oratory of our public functionaries, we shall appear to stand infinitely higher in every point of universal preparatory education than any other nation whatever." "However, I must declare my conviction and give my testimony that all true and living results decrease in proportion as the means and the pretensions increase in number, artifice, and complication. History, modern languages, and their literature, and even geography and natural history, are studied less generally, less zealously, and less successfully than in the corresponding academic spheres in England." I need hardly remind you that I have been speaking of the German Universities as we have hitherto known them. What effect the recent revolution in Germany may have on the interests of learning and education in that country, this is not a proper occasion to speculate. But the admirers of the German Universities seem to look with some apprehension on the consequences of their contact with free institutions and political liberty.

Free-Trade in Teaching.—The most striking points of resemblance, as it appears to me, between the German system and our own, occur in the classes of the population from which the students are drawn, the absence of religious or other exclusive tests, the cheapness of the student's life, and the freedom of thought and speculation enjoyed by the professors. With a special view to these points of resemblance, it has been suggested that another feature in the German system might be adopted in Scotland, subject to some limitations—I mean that free-trade in teaching within the University itself which gives the student a choice of teachers on any subject which he is about to study. In our Faculty of Medicine this principle has already been to a great extent recognised and acted on. In the Faculty of Theology it is, for obvious reasons, more difficult to give it full effect, though even within this Faculty extramural teaching has in our University been liberally recognised as a considerable portion of the qualifications for a degree. In the Faculty of Law, the number of students, is scarcely large enough to afford encouragement to competition among teachers. It is, therefore, in the Faculty of Arts that the adoption of this principle is seriously recommended as a novelty. The project, as originally propounded and ably maintained in argument by two gentlemen connected with the University of Aberdeen, is that graduates should be allowed to teach any subject or branch of science or learning taught by a Professor in a University, and that this teaching should be as available as that of the professor to qualify for a degree in Arts; the conditions being, that to enable any graduate to undertake such teaching, he should receive from the University Court *licentia docendi*, that in granting such licence the University Court should be limited in their choice to graduates who have distinguished themselves by taking their degree with honours or the like, that the graduate receiving the licence should exact fees of equal amount with those paid to the Professors, that he should not be connected, as a teacher, with any other educational institution, and that he should not engage in private tuition. The chief advantages of this new arrangement are represented to be that when by any accident a chair is filled by a professor who, though learned and able, has not a special talent for teaching, it may be in the power of students to resort to a better teacher, and that liability to competition may act as a stimulus to activity and zeal on the part of all the Professors. The object, it is said, is not to force competition, but only to permit it when required. And therefore the competing graduate is to be placed in a position of disadvantage, without endowment, dependent on the fees of the students for his emolument without the prestige of the Professor's name and office, without a seat in the Senate, perhaps also without the advantage of delivering his lectures within the walls of the University. No graduate, it is contended, will compete on such terms with the Professor unless there be urgent need for his services; and if there be, why should the students be deprived of these services only to maintain a monopoly? The monopoly protects the Professor only when he is unable to protect himself. If he be efficient, he requires no such protection. Even if a graduate should be found adventurous enough to embark in a competition with an efficient Professor, the loss to the Professor of a few of his students would be amply compensated by the wholesome effect of rivalry in stimulating his own energies and rendering his work more satisfactory to himself as well as to others. Thus dull Professors only will suffer from the change; while dull Professors will be dull no longer, but break forth into new vigour and life; a race of teaching graduates will be brought into existence, and to some extent encouraged, who will contribute to raise the reputation of the University, and in the end be eligible candidates for Professors' chairs; while any Professor who has not the faculty of communicating his learning may be left to the enjoyment of that leisure which some so much desire, for the cultivation of high scholarship, or the uninterrupted pursuit of scientific investigation. Such, I think, is a fair statement of the grounds and reasons of a project which, even if liable to grave objections, is entitled to respectful consideration. Regarded as an abstract question, the arguments in its favour are difficult to answer. But we are bound to examine its merits in the light of practical expediency as affecting our own University. Its supporters entirely avoid the danger which is incident to a general recognition of extramural teaching as a qualification for a degree. Such indiscriminate recognition is only the first step towards a realisation of that false theory which leads a University to demit its high prerogative of training those who are to receive its degrees. A University which does not teach is, in my view, not a University at all. It is the embodiment of a modern idea—an examination board created for the purpose of graduating all who can come up to a certain standard in examination. This may be a useful institution. It may, in the opinion of some, be preferable to a University. This is not my opinion. But, at all events, it is not a University, however it may usurp the name. But while the supporters of this project guard against so dangerous a tendency, I cannot help thinking there is a fallacy pervading their arguments from assuming too lightly that the Professor's office and teaching constitute a monopoly. A Professor in a University is no more a monopolist than a teacher of a special subject in any other educational institution. Those who don't like his teaching can go elsewhere for instruction—that is, they can go to some other institution where the teaching of the particular subject is in better hands. The only monopoly is in the University itself, or rather in the whole of the national Universities; and that monopoly consists in the power of graduation, coupled with endowments which secure, or are intended to secure the best men that can be found to fill the Professors' chairs. Speaking in this place, I cannot permit the lawfulness and expediency of that monopoly to be brought in question. On the contrary, we are all bound to do what in us lies to support and justify and strengthen it. The case supposed of an incompetent Professor constitutes no objection to the monopoly enjoyed by the University, or to the system which it represents, but only indicates mal-administration somewhere, probably in the exercise of patronage. It may, however, happen that, with the best patrons, and the purest exercise of their functions, an eminent man may be placed in a Professor's chair who is devoid of the peculiar gift of teaching; and how shall we resist the argument that, for such an evil there ought to exist within the University a possible remedy, by allowing competition on reasonable conditions? This is a question of importance and difficulty on which I am by no means prepared to pronounce an opinion. I have offered for your consideration some views in connection with it, which I think it would be unwise to overlook. I would further suggest that the salaries of our Professors are not such that it is safe to try experiments. For if we create competition which has the effect of starving both competitors, we shall probably do little practical good immediately, and may do great mischief in the end, by deterring men of the stamp we should desire from offering themselves as candidates for our chairs.

Increasing necessity and demand for the Institution and Endowment of additional Professorships.—The development and cultivation of new sciences, the creation of new professions and employments requiring the exercise of cultivated and matured intellect, as much as those which formerly monopolized the name of the learned professions—these are facts in the progress of the world's history which demand something more than improvement of our existing means of instruction. That this extension of our teaching must be provided without delay, if our Universities are not to abandon their noblest function, of providing adequate instruction for all whose prospects in life, or whose personal desires, lead them to seek the benefits and blessings of the higher culture, is a conviction which, the more I consider the subject, I find it the more difficult to resist. But these considerations need cause no uneasiness or alarm to any friend or admirer of our ancient Universities; for such extension is not incompatible with the maintenance of these institutions in their integrity, and the introduction of new sciences or branches of learning will not necessarily interfere with the existing curriculum of study in any of the Faculties. No one, I think, who is practically acquainted with the working of our academic system, particularly as regards its capacity of expansion, can share in such apprehensions. So far am I from dreading any evil consequences from what I venture to call, for the sake of distinction University extension, that I believe one of the most important boons which have been conferred on the University of Edinburgh of late years has been the endowment of the Chair of Engineering by an enlightened and judicious benefactor, to whom we are otherwise under deep obligations. In the development of the material resources of the country, the work of our engineers is second to none in importance and in immediate and startling effects. Natural wealth is rendered available, and the latent energies of a population are awakened into useful and productive action, only in proportion as the country is rendered accessible by roads, bridges, canals, and railways. Foreign commerce, as we now understand and practise it—intercourse with every race of mankind in every corner of the habitable world—might have remained a hopeful dream rather than a present reality, had it not been for the application of steam to navigation, the advance in the art of shipbuilding, and the construction of improved harbours, docks, breakwaters, and lighthouses. But for the employment of practical engineering in aid of agriculture, large tracts of land which yield abundant crops, and are fitted for human habitation, would have remained in their original condition of unreclaimed bogs, salt marshes, or sterile moors. The great works of the engineers, stupendous and overpowering as they seem to the outward sense, are yet more interesting and impressive as monuments and landmarks of the advancing tide of civilisation. The men by whom such works are planned and executed must not only possess unusual vigour of mind and body, but must have been subjected to a special and laborious training; for these ends could not be attained without a thorough knowledge of the principles of mathematical and physical science, and an aptitude and readiness in their application to every new want and emergency. It is true that some of the greatest of our engineers have been men of humble origin and imperfect education. But while this lends the charm of romance to the story of their lives—their struggles, disappointments, and triumphs—it cannot be disputed that greater advantages of education might have saved them much useless toil and consuming care, and that their successors will be best prepared for their work by such an education as will not only furnish them with the highest professional knowledge, but cultivate and develop the intellectual and moral powers to the fullest attainable perfection. If this be anything like the truth, it cannot be below the dignity, or inconsistent with the functions of a University, to provide such education; nor can anyone be heard to dispute the claim of engineering to a place among the learned professions. Should Scottish Universities be among the first fully to recognise this claim, so much the better, and the more natural; for Scotland is the native land of Rennie and Telford, and their countrymen can never forget that most of the great engineering works in the United Kingdom during the past generation bear the impress of their genius, and that within Scotland itself notable triumphs of skill and perseverance over the powers of nature were achieved by two Scotchmen, father and son, less known beyond the limits of their own country, but whose name stands for ever associated with the Bell Rock and Skerryvore. I trust that the institution of the Chair of Engineering may be followed by other additions to the Professoriate which are greatly needed. It requires no argument to show that the great department of natural history (even when botany is otherwise provided for) is far too wide a field for the labour of one professor. If the domain of natural history embraces the globe and all that it contains—earth, air, and water, and every description of animal and vegetable life—it would seem naturally to resolve itself into these corresponding divisions—(1) Geology and mineralogy, (2) metereology, (3) hydrography, (4) zoology, (5) botany. It would be perhaps to ambitious too propose that each of these divisions should form the subject of a separate professor's work. But when we have it already practically admitted that botany alone furnishes ample work for one Chair, and we consider the vast recent progress of knowledge in natural history, it is surely not too much to require that the two great branches of zoology and geology should be represented by separate professorships, Leaving zoology to be taught by the present Professor of Natural History with such an addition to his salary as will compensate him for any consequent loss of students, I hope we may ere long witness the endowment of a chair of Geology and Mineralogy, embracing the widely interesting subjects of metallurgy and mining. I might easily run up a catalogue of other subjects in which the teaching power of our University is still defective. The great department of history and the philosophy of history, modern languages and their literature, political philosophy and economics, including the pure science of jurisprudence, have all strong claims on our attention when we are thus reckoning our possessions and our wants. But I trust the interests of physical science, and the admiration which its wonderful progress commands will not blind us to the still greater importance, in an educational point of view, of other and old-fashioned studies. The cultivation of physical science alone has never yet in the world's experience produced a great statesman, orator, philosopher, or poet; and I am much mistaken if the best men in the department of physical science itself, the most successful in investigation and discovery, the men of highest inventive genius, have not enjoyed the full benefit of that culture and training of the mind which, according to the Scottish theory, ought to precede the acquisition of all professional or other special knowledge. I am not about to enter upon the great controversy between "culture" and "useful knowledge," on which so much has been recently spoken and written. I have more than once had occasion in public to state my opinions on that question, and I abstain from repeating them now, the more especially as you have by this time heard quite enough, perhaps more than enough, of my opinions; and the tone of my address has been throughout so dogmatic that I almost expect the Professor of Greek to rebuke me in hexameter verse:—

"*Δόξα μὲν ἀνθρώποισι κακὸν μέγα, πεῖρα δ' ἄριστον.*"

Let me conclude with the expression of my earnest hope that whatever diversity of opinion on this question may exist even within our own walls, the University may be enabled to meet and satisfy all the educational wants and desires of modern times, without deserting any part of her great duty to teach men to know themselves, to fathom the depths of their own life, and, by the study of the laws of thought, of the science of spiritual language, and of the rules of human conduct, to grow in wisdom and virtue as they increase in strength and in knowledge.

◆

USE OF TOADS.

The *Connaisance Médicales* states that of late years French horticulturists have followed the example of the English ones, and peopled their gardens with toads. These reptiles, it seems, are determined enemies of all kinds of snails and slugs, which, it is well known, can, in a single night, destroy a vast quantity of lettuce, carrots, asparagus, &c. In Paris, toads are sold at the rate of 2fr. 50c. a dozen. The dealers in this uninviting article keep it in large tubs, into which they plunge their bare hands and arms, without any fear of the poisonous bite to which they expose themselves. Toads are also kept in vineyards, where they devour during the night millions of insects that escape the pursuit of nocturnal birds, and might commit incalculable havoc on the buds and young shoots of the vine.

Lecture.

ON FIBROUS TUMOURS OF THE UTERUS.

By James Palfrey, M.D.,

Assistant Obstetric Physician to the London Hospital; formerly Obstetric Physician to the Farringdon Lying-in Charity, and to the Metropolitan Free Hospital, and to the Surrey Dispensary, &c., &c.

Lecture II.

If, gentlemen, the somewhat extended remarks I made to you in my first lecture upon the pathology of fibroids appeared wearisome, I shall ask you to bear in mind the great importance of that portion of our subject, and remember, I pray you, that we are now investigating conditions that will every day come before you as practitioners, for of all organic diseases of the womb fibrous growths are the most frequent, hence I am sure you will not regret the time spent in a careful and complete study of these matters. Before, however, proceeding to the consideration of the etiology of these hard tumours of the womb, I am anxious to supply an omission which has occurred in my former lecture. You will remember that when speaking of the changes that take place in these growths I pointed out to you that they were liable to undergo a kind of false ossification, a change to which the term calcareous degeneration has been given. To this remark permit me to add that very rarely these tumours become the subject of an exactly opposite condition. Now and then they soften; very seldom indeed do we see examples in which this change takes place; and when it does present itself it is usually the result of some great pressure or actual injury to the uterus in which the neoplasm is developed. The tumour, I say, softens down, becomes disintegrated, and is discharged *per vaginam* in pieces, the size of which varies. This process, which I need hardly tell you, is usually accompanied with severe constitutional disturbance, is one of considerable danger, and occupies some weeks or even months in its completion. One case only in which this change has fallen under my own observation can I describe to you. It occurred in 1857 in the person of a married woman aged fifty-one, who had for several years been under the care of Dr. Lever, at Guy's. During that time she had been treated for a large fibrous tumour which with the uterus had risen out of the pelvis. While crossing a road she had been knocked down by a light cart, the wheels of which passed obliquely over the lower part of her belly and lower extremities. Dr. Lever was called to her on the second day after the injury, when I saw her with him and watched the case to its termination. For twelve days after the accident this poor woman presented all the conditions observed in post-partum hysteritis in its most active form. On the thirteenth day a uterine hæmorrhage of considerable quantity supervened, and with this occurred an amelioration in the pain and uterine tenderness. This again on the fifteenth day was preceded by a most offensive vaginal discharge consisting of putrilage and masses of softened tissue, which were expelled in considerable quantities. This continued (with well-marked hectic) until the twenty-ninth day from the accident, when, upon being moved from one side of the bed to the other, she complained of sudden and severe pain in the left groin extending to the median line. Vomiting and collapse ensued; and this woman died with all the symptoms of perforation of the peritoneal sac on the morning of the thirtieth day from the receipt of the injury. I regret to say no *post-mortem* was permitted in this case; but the rapid diminution in the size of the tumour, the decrease corresponding with the date of the appearance of the discharge from the vagina left no doubt in our minds at the time that we were dealing with a case of softening and expulsion of a fibrous tumour, such softening being caused by injury to the growth itself. Had this woman's life not been cut short by the deplorable accident of perforation, she would, I believe, have recovered not only from the effects of the injury, but she would also have been rid of her voluminous uterine fibroid.

And now let us for a few minutes consider the causes of fibrous tumours; and here I much regret to tell you that our present knowledge is of the scantiest possible nature, and upon no portion of our subject is the information I have to present to you of so unsatisfactory and uncertain a character. Such facts, however, as we are in possession of I will place before you; and

First, I will remark that *age* appears to exercise very little, if any, influence upon the production of these hard tumours of the womb. Not long ago I was able to show you an undoubted case of fibroid, attended with profuse hæmorrhage, occurring in a girl of eighteen years; and only last week a woman of sixty-two years of age was sent down to my room by one of my colleagues. She was found to be the subject of a large fibrous growth. This patient had been *apparently* in excellent health until a period dating but three months before her application at the hospital for the relief of a persistent vaginal tenesmus. These instances, however represent the extremes in age. I think upon this point you may with safety accept the rule that these tumours appear for treatment in the largest number of cases in women between the ages of thirty-four and fifty-two years; but always bear in mind the probability that growth in these cases has been present in the uterus for some years before their presence became manifest to the patients by any symptom that would lead them to seek your assistance.

Social condition likewise has but little to do with the frequency with which we meet with these cases, for the married and single alike are the subjects of them, but this one circumstance has long been apparent to me that women who have from any cause (syphilis I believe, excepted) been the subjects in their early sexual life of long continued, uterine engorgement appear at a subsequent period to be peculiarly obnoxious to fibrous growths. Again, there exists no doubt that by far the larger number of cases of this disease are found in women who have not borne children, and my own observation has led me to conclude that single are oftener found to be sufferers, than married women, although it is right that I should tell you that this experience does not coincide with that of other observers; for Dr. West tells us that of ninety-six women affected with non-pediculated fibrous tumour, eighty-two were married—however that may be certain it is, that these growths exercise a great influence in fecundity, for as soon as they have attained a size sufficiently large to alter the normal position of the womb and so interfere with the healthy circulation through that organ, they are (if left to themselves) an undoubted cause of sterility, and even where the growth is yet of small size and conception occurs, abortion almost invariably results in the earlier months of pregnancy. Again, the conditions we are considering are not found I believe, in women of any particular temperament. Dr. McClintock has noticed that a considerable number of his cases of fibroids occurred in women of a scrofulous habit. Since reading his work some years ago I have watched this point, but I cannot say I have noticed a greater number of these fibroid cases in this class of patients than in women of other diathesis or temperament. I must not forget to mention to you that Dr. Gardner, of New York, has made known to us a very interesting fact, he tells us that fibrous tumours of the womb are more constantly met with among the negroes, than among the white population, so common are these neoplasms met with in blacks, that the women of forty years of age and upwards without a fibroid, would be the exception, rather than the rule, and few *post-mortems* take place of coloured women, without one or more of these tumours being found in the uterus. This remark, gentlemen, concludes all I can tell you of the causes which produce these bodies. We will now pass on to consider the symptoms which are found to accompany fibrous tumours, and upon this point let me at once ask you ever to bear in mind the facts I have already stated, but which I venture to repeat that it is quite possible, and more, it frequently happens, that a fibrous body may exist within the uterine wall, and may progress in its development to a considerable size, and yet may give no evidence of its presence there, the patient being wholly ignorant that any change is impending in her uterine health, and not unfrequently I am sure you have seen women present themselves to us complaining only of a " little whites," or a " slight bearing down " upon prolonged exertion, who, upon examination have been found the subjects of large fibrous tumours. Again, have you not been present in the dead-house, at the inspection of the uteri of women, who during life have presented no symptom of disorder of the uterus, but in the examination of whose sexual organs was revealed a growth or growths of this character which was wholly unsuspected when alive. I am sure you have, and this fact it is important at all times to keep before you. It is, however, fortunate that in the majority of instances the presence of a fibrous growth is soon manifested by phenomena, both of an objective and subjective character of great importance; and let us see what are the symptoms which we usually meet with in these cases. Taking them in the order of their appearance: hæmorrhage undoubtedly stands first, and you will find the amount of the bleeding bears an intimate relation to the position of the growth in the uterine wall. Very early as a rule in the history of a case of fibroid disease, the patient notices that her menstrual period is not only prolonged, but is profuse, being attended with the expulsion of clots of greater or less size, this bleeding being ushered in with pain of greater or less severity which at times, constitutes in these cases a true dysmenorrhœa. After a time, this bleeding is apt to occur *during the interval of a period*, and then it constitutes a "*metorrhagia*" in contra-distinction to that prolonged bleeding which happens *at the period*, and which we denominate "*menorrhagia*." When the growth becomes very large, this hæmorrhage may continue many days, and be very profuse, exhausting and draining the patient, reducing her powers to the lowest degree. Respecting the cause of this frequent and serious bleeding, opinions are divided, some obstetricians believe the hæmorrhage is the result of profound congestion of the whole organ, others again consider that the cervical canal being gorged with blood, which being subject to pressure from above, is unable to return, nature from time to time relieves this engorgement by pouring out some portion of the contents of the loaded vessels through the cervical mucous membrane; many other theories on this point have been promulgated, none of them, however, have appeared to me completely satisfactory, and at present, my mind being unsettled upon the question, I cannot with certainty instruct you upon the precise cause of this hæmorrhage. Certain it is, that the symptom is more constantly present in the submucous than in either of the other varieties of fibrous tumours—in fact, it seldom proves a troublesome complication of interstitial disease, and still less often in sub-peritoneal growths. Another symptom, also, which early makes its appearance in the interval of the bleeding, is a *mucous discharge*, which you will find, as the disease progresses, gives place to a discharge of a more watery character. The same observation, however, applies here that we made just now when speaking of the hæmorrhage; in cases of the sub-peritoneal and the interstitial bodies—the disease may run its whole course without any such inconvenience presenting itself, and I have, at this time, under my care a lady, the subject of a considerable interstitial growth, which has certainly been present for eight years, but which has been unattended by either prolonged menstruation or any notable leucorrhœa. In the next place, we must speak of lumbar and hypogastric pain, which is usually of a shooting or tearing character, and which is often described to us by sufferers as resembling the pains which precede abortion. I need hardly remark that this pain varies in intensity in different instances and at different times in the same instance, from a painful sensation merely to a continual wearing symptom of unbearable severity. You will readily believe, I am sure, that to the above-named symptoms are soon added vaginal tenesmus. This, I may remark, is a condition which, more than any other, taxes our resources to relieve. Passing on, we find dysuria a constant trouble in these cases. In some, the painful micturition alternates with a simple difficulty in emptying the bladder; in other cases, the first symptom we are called upon to prescribe for is a continual desire to pass water, and this incessant effort I have often seen followed by profound exhaustion. These latter symptoms depend upon the size and position of the tumour; if it be small and placed in the fundus they may be altogether absent; should the growth be of moderate size and situated in the anterior wall of the womb, these vesical symptoms will give great anxiety and trouble. In the larger growths, but which have ascended beyond the pelvic brim, these bladder symptoms will not be complained of; but if this tumour not only be of considerable size, but have become œdematous, which not unfrequently happens, and is still contained *within* the pelvis, pressure symptoms of a grave nature may at any time supervene. Among the less important symptoms which attend the development of fibroids in the uterus may be mentioned, frequently recurring uterine colic, flying pains in the lower extremities, œdema of the feet and ankles, difficult or painful defæcation, descent or even prolapse of the uterus; and the presence of most of these, you will at once see, is indicative of pressure more or less great. The duration of these various and variable symptoms which I have just mentioned to you is very uncertain; usually these cases progress year after year, the distress of the patient increasing with the size of the tumour; the repeated hæmorrhages sooner or later producing a state of intense anæmia, this condition in turn being frequently complicated by cerebral or nervous symptoms, such as convulsions, cephalalgia, or cardialgia, one or other of these troubles preponderating in proportion to the gradual or more rapid diminution in the quantity of the blood; or it may be that symptoms appear the result of changes that have ensued in the composition of that fluid, or long continued attacks of pain may be succeeded by vomiting, nausea, or troubles of digestion and assimilation; or to the patient's malady is not unfrequently added all the tortures of confirmed hysteria, or it may be that many, of these complications combined present for our observation a scene of constant suffering and distress. Let me close this very general outline of the symptoms of fibrous tumours by remarking to you that happily it is a circumstance which we comparatively seldom meet with, that an attack of bleeding proves immediately fatal, although very frequently the hæmorrhage is so violent as completely to blanch the patient. On two occasions only have I seen death immediately result from this form of hæmorrhage; in both instances the women were the subjects of sub-mucous growths of large size; in both, the patients were already greatly reduced by previous bleedings and want of care and attention, and so wholly unable to withstand any longer the effects of this flow—draining from their blood vessels. At our next meeting I propose to consider the interesting subject of the diagnosis of fibroid growths.

(To be continued.)

TREATMENT OF RUPTURE OF LIGAMENTUM PATELLÆ AND OF TRANVERSE FRACTURE OF PATELLA.

M. SISTACH is of opinion that position and immobility for a sufficient length of time are quite sufficient to effect a good cure, without any use of the compressive bandages and apparatus so generally used, which are liable to do harm rather than good, preventing the nutrition of the limb, and specially the formation of the new material which is to unite the divided ends of the tendon, causing atrophy of the limb and local scurvy.—*Gaz. Med. de Paris.*

Hospital Reports.

METROPOLITAN FREE HOSPITAL AND FARRINGDON DISPENSARY.

FURTHER CASES OF SYPHILIS TREATED WITHOUT MERCURY.

By Charles R. Drysdale, M.D., M.R.C.P., F.R.C.S.,

AND

Robert W. Dunn, Esq., M.R.C.S.,

A part of which was read at the Harveian Society on March 18, 1869.

(Continued from page 331.)

Case 20.—A. P. came under the care of Mr. Dunn, February 1, 1865, suffering from syphilitic sore throat and roseola. His body, face, and extremities were covered with the eruption. Patient had contracted the infection some time before he appeared, and there was a hard indurated cicatrix on the penis, with multiple enlargement of glands in left inguinal region, for which he had not had any treatment. ℞ Potassæ chloratis, gr. v.; acidi hydrochlorici diluti, ♏x.; aquæ ad., ℥iss., t. d.; and gargle with the following gargle:—Infusi catechu, ʒiv.; acidi sulphurici dilute, ʒj.; aquæ, ℥viij. The patient was seen frequently after this, and gradually recovered. March 20th. He was discharged, as being too well to require to attend. Induration not quite gone. No relapse has been heard of since that date.

Case 21.—M. H., a man seen by Mr. Dunn, July 14, 1865, with indurated sore on foreskin and penis. Four weeks before this he had observed a sore. ℞ Mist. potassæ chloratis and lotio nigra to sore. August 9th. Sore quite healed; glands in groin still indurated. ℞ Potassæ iod., gr. ij.; decoct. cinchonæ, ℥j., t. d. 29th. Syphilitic angina; induration still remains. Repeat mist. potassii chloratis. ℞ Potassæ chloratis, ʒj.; pulveris aluminis, ʒij.; aquæ, ℥viij., for a gargle to be used frequently. September 6th. Feels much better; a very slight attack of roseola. 21st. Better. October 14th. Discharged. No relapse since then.

Case 22.—B., aged eighteen, indurated sore on labium, enlarged glands in both groins. First noticed something wrong four weeks before seeing Mr. Dunn, February 22nd, 1868. At that time had slight syphilitic roseola. ℞ Misturæ potassæ chloratis, ℥j., t. d. March 22nd. Rash well out. May 3rd. Sore healed; rash gone; sore throat. Gargarisma acidi cum catechu. June 6th. Discharged, all symptoms having disappeared.

Case 23.—H. B., a young man, aged twenty-five, Aug. 10, 1868, seen by Mr. Dunn, with indurated glands in the groin and indurated sore on penis. Patient had contracted a sore two months before. Under local treatment, without any particular internal remedy, on August 29th the sore was healing, but still indurated, roseola appearing. ℞ Syrupi ferri iodidi, ʒj., t. d. Sept. 10th. Sore healed. 16th. Syphilitic angina and roseola; induration nearly gone. ℞ Misturæ potassæ chloratis, ℥j., t. d.; and gargarisma catechu. October 4th. Psoriasis palmaris; roseola gone; throat well. May. Discharged free from symptoms. No relapse since.

Case 24.—A. G., aged twenty-four, seen by Mr. Dunn, August 26, 1868, with indurated sore on penis, and enlargement and induration of the glands in the groin. The sore on the penis had not appeared until ten or twelve days after intercourse. To take misturæ potassæ chloratis, ʒj., t. d. September 10th. Sore healed. December 4th. Roseola syphilitica. Repete misturam. January 6th. Much better. Repete. February 13th. Mucous tubercles on tongue and lips. March 2nd. Discharged cured. No relapse since.

Case 25.—J. O., seen Jan. 28, 1869, by Dr. Drysdale, with indurated sore of foreskin, and enlargement of glands of groin of both sides. Five months ago this patient had connection with a prostitute in Christiania, and he asserts, with great appearance of truth, that this is the only time that he had deserted his own partner's couch. On Jan. 4, 1869, he saw first the small sore on the foreskin. No sore throat or roseola. The sore was dressed with lint and water dressing, and the patient is still under observation, the sore having disappeared April 15, 1869. No further symptoms as yet.

The following cases show how well infants affected with syphilis do without mercury, far better, the authors think, than they do when mercury is administered.

Case 26.—John I., aged eight months, was seen by Dr. Drysdale on the 27th November, 1866, with a syphilitic dry papular eruption on the face, buttocks, and scrotum; the child was hoarse, and snuffled a little. Mother had perceived the eruption first when the child was five months old, and it at first covered the whole body. The patient was treated by Dr. Lomas for a time by oleum morrhuæ and steel wine, and also by syrup of the iodide of iron. This treatment was continued by Dr. Drysdale, and the child recovered. The mother, aged thirty-one, at the age of twenty-six had suffered from secondary eruption, and her husband at that date was in the London Hospital with a "bad arm." Before she had the eruption she had borne four healthy children. She was pregnant when suffering from the eruption. She was then delivered of twins, one of which died aged five weeks, the other still lives, and is well. She had herself been treated by pills and lotion for some months. No more births since until this one.

Case 27.—James Bailey, aged twelve months, seen by Dr. Drysdale, April 30, 1862, with swelling of the right knee and elbow, snuffles, and afterwards papular eruption. The mother of the child was scarcely affected, at least no history could be made out; the father had some syphilitic rash. This child was treated by Dr. Drysdale, and afterwards by Mr. Allingham, by two grains of chlorate of potash in water thrice daily, by cod-liver oil, and by syrup of the iodide of iron in small doses, and recovered perfectly in two months. It was a very severe case, as the joints were much inflamed, and there was considerable constitutional excitement, caused by the joint disease.

Case 28.—George Dods, eleven weeks old, was seen by Dr. Drysdale, May 17, 1862, with papular eruption of a dry character on buttocks and arms, and with cracks at the side of the mouth and great enlargement of the suboccipital glands. The mother had, before this one, had three children and a miscarriage; she had been married five years. One of the children born alive lived one month, one lived two and a-half hours, and one lived six weeks. The father was reported to be "gay," and to have suffered from eruptions; but, curiously also in this case, the mother had neither any present symptoms nor any past history of having been infected. She was rather pale. This little patient was treated by small doses of chlorate of potash in water, two grains three times a day, and was seen by Dr. Drysdale, in 1867, quite well and without any symptoms of syphilis. This case is instructive, as showing how the system gradually becomes able to generate healthy children, and also as being apparently in contradiction to M. Cullerier's law, that the mother is *always* infected when syphilitic infants are borne by her. Mr. Hutchinson's views are quite opposed to those of Cullerier on this point.

Case 29.—John Spillan, aged five months, was seen by Dr. Drysdale, 21st April, 1864, with a dry eruption on the buttocks, snuffles, and much enlargement of the posterior cervical glands. It appears that, previous to her bringing this child, the mother, eight years ago, had been ill from syphilis, for which, she says, she took a great deal of mercury. Her first child, born before her attack, was well; but, since then, she had always miscarried. The child made a good, though slow, recovery in two months on small doses of chlorate of potash, gr. ij., t. d., and cod-liver oil, with syrup of the iodide of iron subsequently. Here, again, the system seems gradually to have got rid of the poison, so as to enable the mother to have a viable child at last.

CASE 30.—Charles C., aged forty-five, suffered in 1851 from secondary syphilitic eruption, crusts in hair, and other slight symptoms of constitutional syphilis. His treatment was hardly to be called treatment—*i.e.*, patient took occasional doses of iodide of potassium, and recovered his health completely. In 1869, this patient has three healthy children by a second wife, the first partner having succumbed to phthisis; none of the children were infected. This case is given as an illustration of the frequently observed exemption of children from all taint when only the father has been syphilitic.

CASE 31.—John B., aged five months, seen by Dr. Drysdale, February 4, 1863, with eruption over body, squamous and dry in character, snuffles, and posterior cervical glands enlarged. This was a most unfavourable case, as the child's mother was a wet nurse, and had left her own child to be brought up by hand. Nevertheless, the child recovered by careful attention to diet, and under doses of two grains of chlorate of potash thrice daily at first, and a few drops of syrup of the iodide of iron subsequently. The child was alive in 1865.

CASE 32.—Sophia Aldridge, aged seven weeks, seen by Dr. Drysdale on the 2nd July, 1866, with snuffles and dry eruption on buttocks, and with posterior cervical glands enlarged. The mother had eruption two years before, and the father also. Snuffles are reported to have been seen a week before coming to the hospital. This child recovered by simple treatment.

CASE 33.—John Thomas, aged eight months, seen first by Dr. Drysdale, 27th November, 1866, with dry papular eruption on buttocks, snuffles, and mucous tubercles on scrotum. The mother, aged thirty-one, had secondary eruption five years previously, and husband also. No birth since then. Treatment by chlorate of potash was successful in this case.

◆

COCKSCOMBS.—An ingenious individual, knowing the immense consumption of cockscombs in Paris for *ragouts*, *coquilles* of cockscombs, and *vol-au-vents*, and seeing the high prices they commanded, owing to the limited supply, set to work to minister to the demand, and duly established himself as a manufacturer of cockscombs. So extensive was the trade done by him that he found it necessary to set up a small steam-engine. He was a great enthusiast, and was accustomed to pride himself upon the artificial cockscombs which emanated from his *atelier* being greatly superior to the natural article. With a modesty uncommon among his countrymen, he styled himself as a "rival" only of nature, who was not thus subjected to a too humiliating comparison. Nevertheless he would say, "Nature's productions, in the matter of cockscombs, abound with unpardonable defects; there are not two of them alike; whereas, all of mine are not only beautifully proportioned, but dentilated at the edges with the utmost exactitude. Mine, in fact, are the work of an artist, and art is simply nature perfected by the genius of man. Nature makes the marble, but it is man who carves a statue out of it; nature produces a woman, but it required a man to produce the Venus de Medicis, an ideal that nature is incapable even of imitating." This is the way our artist goes to work. He takes the palate of a bullock, calf, or sheep—either will do, though he prefers the first. After having blanched it in boiling water, he macerates it, and detaches the flesh of the palatic vault without in the slightest degree deranging it, and then places it under a stamping machine, which punches out cockscombs more perfect in shape than those produced by nature, yet sufficiently resembling them to deceive the connoisseurs. Still, there is a way of detecting the artificial production. The cockscombs of clumsy nature have *papillæ* on both sides, whereas those of art have them only on one. Counterfeit cockscombs are sold as low as four sous the dozen to poulterers, keepers of restaurants, pastrycooks, &c., and at six sous to cooks in private families. The inventor, seeing the multitude of statues set up under the Second Empire, is naturally astonished that one has not been erected in his honour; but he sensibly resign himself to what he calls the fate of genius, which is, he says, never to be really appreciated until after death.—*Once a Week.*

SENSATIONALISM.

THESE are days of sensationalism! Nothing will go down unless it is sensational!! Advertisements must be sensational. If "Shoddy and Co." wish to advertise their coats in the *Times* newspaper, they do not, as we say, put an advertisement in, but they have a whole column to themselves, repeating the word "coats" seventy times in large letters in seventy paragraphs; and it would be a hard thing, indeed, if one of the seventy repetitions did not strike the eye of a few. Look, again, at the titles of modern novels and modern plays. Anything quiet is voted dull, heavy, and a bore; and the world at large, whose favourable appreciation of an undertaking is necessary for its pecuniary success, would place on one side volumes whose sole merit consisted in the fact that they were the learned productions of learned writers, who had laboriously worked out facts and then given them to the world. We have no doubt Mr. Mudie would tell us that some novel, teeming with murders and the suicides of ardent though wretched and refused lovers, and such like trashy sensationalisms, have a hundred times greater circulation than the work of some great literary genius, who does not merely write to feed the morbid appetites of some young ladies who have just left school, but for the instruction of those whose minds crave and thirst for knowledge. People now-a-days care little for the stage unless there is something terrible to be witnessed in the shape of a young lady being torn to death by a locomotive. Our forefathers were contented with visiting a quiet exhibition of conjuring, but now, nothing short of "beheading a lady" will go down with visitors to such like exhibitions.

We regret to say sensationalists in medicine are not wanting. Some two years ago there was an outbreak of cholera in the East End of London. Dr. Letheby, who probably knows more of the water supply than any man living, and who may be regarded as the parent of the water question (for he was the first to direct serious attention to its influence on disease), carefully investigates all the circumstances of the outbreak, and comes to the conclusion, for reasons it is unnecessary to state here, that there was nothing to justify the opinion that the water was the cause of the mischief. In this the Health officer of the district agreed with him. But this carefully considered opinion did not suit some of the public, nor some of the public officers; and if Dr. Letheby was unable to prove that water was the cause of the cholera, why somebody must be found who will be able to prove it is. A certain gentleman (of course we do not question but what he was fully convinced in his own mind) succeeds in this, and his ideas are instantly adopted by the Registrar-General in his report; and thus a truly sensational report is prepared, and one exactly suited to the requirements of a sensational age. Is it to be wondered at that the public now-a-days trace every disease to the water from cholera down to a whitlow? "Don't you think, Sir, it is the water?" said a patient to us the other day, suffering from rheumatism; and we are bored with that question incessantly.

A sensationalist, however, is only the creature of a day, passing like a butterfly through a mere ephemeral existence; and what is more, with all this public love for sensationalism, which we deeply deplore, we find out it is possible for people to have too much of it. One of the gentlemen who declared water was the cause of cholera in the East End of London proposes himself for a medical officership of health. He is opposed by gentlemen of high professional, and in one case high chemical, attainments. We are not surprised at the non-medical world in the *Times* newspaper being indignant at his being declared ineligible for the post (by the bye, did he ever make a determination of the amount of sulphur in gas?). It is true the gentleman elected has never been a sensationalist, and therefore, of course, he receives no commendation from newspaper editors. He has no connection with the *Lancet*, and therefore is free from the exorbitant praises the staff of that paper so absurdly lavish on themselves.

Yet the last idea of the sensational *Lancet* caps all. A week last Saturday Dr. Letheby read a paper at the Metropolitan Association of Medical Officers of Health, on the water question, in which he took exception to the method of analysis employed by Dr. Frankland, criticised the phrase "previous sewage contamination" used in the reports of the Registrar-General, and protested against sensationalism in reference to water analysis.

Dr. Frankland, who was present, defended the phrase "previous sewage contamination," said that the position he occupied was not one of his own seeking, and expressed continued confidence in his process. He gave his views with that ability for which he is well known, but without any attempt to impugn the authority of Dr. Letheby, or the propriety of that learned gentleman bringing on such a discussion. Mr. Hawkesley, Dr. Carpenter, of Croydon, Mr. Wanklyn, Professor Ansted, and Dr. Odling, were all in, more or less, close agreement with Dr. Letheby, so that few would be disposed to deny there must be some force in his criticisms.

However, the last number of the *Lancet* contains a silly annotation on the discussion, pooh-poohing all this array of authority. The writer, with an audacity not given to higher orders of intellect, rushes madly into the arena, and then, overcome with his own impudence and apparently unable to comprehend the points at issue, turns on the assailant of the hypothesis he has too hastily endorsed, accuses him of "party spirit and temper," and objects to the "unwarrantable assumption of improper motives" that he supposes to be contained in a "protest against the 'sensationalism of the Registrar-General.'"

And so our sensational medical contemporary thinks the word that best describes it, opprobrious. We are sorry to prick so thin a skin, but cannot help asking, if sensationalism be so wrong would not the *Lancet* do well to eschew it, in fact, instead of evincing dislike of the term?

SCOTLAND TO THE FRONT.

Our space is not nearly enough to do justice to the medical topics of the day supplied by Scotland. We have postponed a mass of valuable matter in order to make the necessary room for our Scottish Medical Press on this interesting occasion, and we trust our efforts in this direction will be appreciated by all our readers. The address of the Lord Justice-General cannot fail to interest everyone at a time when education is the question of the day, and when the Universities are, as it were, on their trial. No one is more competent to speak than his Lordship, and no one will be listened to more attentively. His election is in itself a proof of the value set on his opinion in University matters and his labours in the Commission.

This, however, is but a small part of the pressure on our columns from Scotland. We should have been glad to find room for some elaborate criticisms on the installation address, as well as for a quantity of matter supplied by the editorial staff of the Scottish Medical Press and some able correspondents. With such a plethora of material we can only do our best, ask the forbearance of some of our contributors, congratulate ourselves on what we have accomplished in making the Medical Press *the* professional journal of Scotland, and take courage for the future. Scotland is just now well to the front in matters of interest to medical men, and, with a weekly journal at her disposal, has now an opportunity, she has never before enjoyed, of being heard not only in her own schools, universities, cities, and provinces, but throughout the sister kingdoms.

◆

EXEMPTION OF HOSPITALS FROM TAXATION.

A Bill has just been brought into the House of Commons by Mr. Wheelhouse, of Leeds, and Sir Herbert Croft, which is intended for the relief of public hospitals from liability to rating. Its provisions are briefly as follows:

> Whereas it is expedient that institutions established and continued exclusively for the treatment and cure of the sick should be exempt from the charge of county, borough, parochial, and other local rates, in respect of land and buildings occupied by them for the transaction of their business, and for carrying into effect their purposes. Be it therefore enacted, that from and after the first day of October next no person or persons shall be liable to pay to any county, borough, parochial, or other local rates or cesses, in respect of any land, houses, or buildings belonging to any institution mentioned in the schedule of this Act; provided that such institution shall be supported wholly or in part by the annual voluntary contributions of not less than *twenty* subscribers, and shall not make any dividend, gift, division, or bonus in money, unto or between any of its members; and provided also that such institution shall obtain the certificate as hereinafter mentioned.
>
> Before any institution shall be entitled to the benefit of this Act, such institution shall cause three copies of all laws, rules, and regulations for the management thereof, to be submitted in England, Wales, and Ireland, to the barrister appointed to certify the rules of Friendly Societies there, and in Scotland to the Lord Advocate, and such barrister or Lord Advocate shall give a certificate that the institution is entitled to the benefit of this Act, or shall state in writing the grounds on which such certificate is withheld; and one of such copies, when certified, shall be returned to the institution, another copy shall

be retained by such barrister, and the other shall be transmitted to the Clerk of the Peace, and shall by him be laid before the justices for such borough or county, and the justices are authorised and required to allow and confirm the same.

Provided always, that the fee payable to such barrister shall not at any time exceed the sum of one guinea.

Provided always, that in case any such barrister shall refuse to certify, it shall then be lawful for any such society to submit the laws, rules, and regulations thereof to the Court of Quarter Sessions; and justices may, if they think fit, order the same rules to be filed.

Schedule of Institutions to which the Bill applies.

Public general hospitals, general infirmaries and dispensaries; hospitals for sick children; hospitals, infirmaries, and dispensaries for cancer, consumption, and diseases of the chest, epilepsy, eye and ear diseases, fistula, fever, diseases of the heart, contagious diseases, diseases of the bladder, and syphilitic diseases; convalescent hospitals; dental hospitals, infirmaries, and dispensaries; foundling and incurable hospitals; hospitals for midwifery and lying-in women.

◆

SCOTLAND.

EDINBURGH UNIVERSITY COURT.

The University Court met on Monday, the 19th April. Present—Principal Sir Alexandar Grant, Bart., in the chair; Mr. Gordon, Mr. Nicholson, the Rev. Mr. Phin, and Dr. Christison. The following is the official account of the proceedings:—

> "An arrangement made by the Senatus, under which Professor Syme's class is to be conducted during the summer session by Dr. Joseph Bell, was approved of. On further consideration of the best day and hour for stated and other meetings of the Court, it was resolved that they should, as far as possible, be held on Mondays at two o'clock. After hearing parties on the matter of appeals by Professors Muirhead, Turner, and Laycock, and considering a petition from medical students against a resolution of the Senatus to admit a lady to certain of the medical classes this summer session, the following resolution was adopted:—'The Court, considering the difficulties at present standing in the way of carrying out the resolution of the Senatus as a temporary arrangement in the interest of one lady, and not being prepared to adjudicate finally on the question whether women should be educated in the medical classes of the University, sustain the appeals and recal the resolution of the Senatus.' A deliverance upon the General Council's representation of 21st April, 1868, regarding the addition of subjects in natural science to the Arts curriculum was adopted. A communication from the St. Andrews University Court was received, taking a favourable view of the proposal that members of the General Council of any one of the Universities of Scotland should have the use of the library of any other."

GENERAL COUNCIL OF THE UNIVERSITY OF EDINBURGH.

The statutory half-yearly meeting of the General Council of the University of Edinburgh was held on Tuesday afternoon, April 20th. There was a very small attendance of members. The chair was occupied by Principal Sir Alexander Grant, Bart., Vice-Chancellor of the University; and among the other gentlemen on the platform were—Professors Christison, Balfour, Masson, Stevenson, Crawford, Macpherson, and Calderwood; Dr. Lyon Playfair, M.P.; Mr. E. S. Gordon, Q.C., Chancellor's Assessor; Rev. K. M. Phin, Assessor for the General Council; Mr. Alexander Nicolson, advocate, Rector's Assessor; Mr. David Milne Home, of Milne-Graden, Curator.

Some formal business as to the Chancellorship, and the extension of the University building was first of all transacted.

STUDENTS' FEES.

A proposal to charge a fee of 10s. for the preliminary examination for medical students was approved.

ARTS' DEGREES.

It was reported that the Senatus Academicus and the University Court concurred in the changes to be made as to graduation with honours in Arts.

SCIENCES.

A communication was also made from the University Court respecting the addition of science to the arts curriculum. Final decision was postponed for a time.

UNIVERSITY LIBRARIES.

It was then reported that Aberdeen and St. Andrew's Universities were favourable to a proposal to admit the members of the General Council of any one of the Universities to the use of the library of any other, but the reply of Glasgow had not yet been received.

EDUCATION.

Principal Sir A. Grant related what had been done by the deputation sent to London by the members of the Senatus of the Scottish Universities. He disclaimed altogether the idea that the deputation assumed to represent the Universities, and said:—

> We were received in London officially—1st, by the Duke of Argyll, the Lord Advocate being present at the meeting; 2d, by Mr. Forster, the Vice-President of the Board of Education; 3d, by Lord De Grey, President of Council; Lord Granville also being present. We had separate interviews (at which full explanations of the resolutions were given, and objections stated and answered) with the Duke of Buccleuch, Lord Stanley, Lord Kimberley, Lord Cairns, Lord Minto, Lord Colonsay, and Lords Kinnaird, Airlie, and Camperdown. We had shorter interviews, at which briefer statements were made, with Mr. Gladstone, Mr. Lowe, Mr. Bruce, Mr. Crawfurd, Mr. Grant Duff, Sir E. Colebrooke, Mr. Loch, Mr. Ellice, Mr. Parker, and many other Scotch members. We invariably represented that our sole object was to prevent the character of Scottish parochial schools from being impaired by the levelling action of the Revised Code. We pointed out the close connection of these schools with the Universities, and some of the best features of the national character. We urged that the code of regulations for grants to these schools should be drawn up, not by the Privy Council, but by a Scotch board: and in order that such a board might have the confidence of Parliament sufficient to justify its being entrusted with wide powers, and the actual distribution of public money, we suggested that the board should be one, not of an elective character, but appointed by Government, and directly responsible to Parliament. We pointed out that our chief object in these proposals was to obtain a graduated system of grants, not only admitting grants for subjects of liberal instruction—such as grammar, geography, history, mathematics, and Latin—but even assigning higher grants for the higher standards. We were frequently met by the objection that it might not be considered justifiable to apply the taxpayers' money in aid of what was really secondary education. To this objection we replied that the line of distinction between primary and secondary education appeared to us to be an arbitrary one; that what might be called primary education—that is, education natural and suitable for children of the labouring classes in one country might be quite different from that in another country; that the two hundred years of education in Scotland had raised the people to a level above that of corresponding classes in England; and that such men as shepherds in this country thought it a right to be able to afford their children some tincture of an instruction more liberal than the mechanical rudiments.

Mr. Home, Rev. W. Wood, Rev. Mr. Phin, and Dr. Andrew Wood, spoke. It was agreed that no member of the Council was committed to the views that had been expressed by the Principal.

DEGREES IN APPLIED SCIENCE—IMPORTANT DEBATE.

Dr. L. Playfair, M.P., brought forward a motion of which he had given notice:—"That this Council request the University Court to take the necessary steps for obtaining a legal sanction to degrees in applied science."

He said that the degrees which it was proposed to establish were carefully considered by the Senatus, and referred to the University Court, which also approved of them in a formal manner. Although the Senatus of the University Court believed they had power, first, to initiate and then to ratify such degrees, a doubt having arisen on the subject, it was referred to Sir Roundell Palmer, who gave it as his opinion that the original charter which covered all the powers which any Scottish University possessed, was limited by the clause in one of the Papal bulls with reference to Aberdeen; that any Scotch University might give degrees such as were given at Paris or Bologna, but they had not sufficient power without going also to the Privy Council and asking for sanction to give those degrees. Both the University Court and the Senatus withdrew their intention to give those degrees until the sanction of the Privy Council could be obtained, if the University Council was of opinion that they should proceed. Almost all the early Universities arose from a desire to cultivate professions as professions and arts. In the early history of the Universities, the Faculty of Arts was not incorporated with the Universities themselves, but was a pedagogium or preparatory school for the Universities. It was said in Paris that the University arose with the Faculty of Arts, and that the professions were supplemented upon it. The Faculty of Arts certainly arose very early in the University of Paris; but there was a rule in that University regarding the age of students receiving the degree of B.A. in arts which clearly showed that it was a thing preparatory to going into the Universities. After a time, the Faculty of Arts became absorbed in the University, and had a much larger scope than that with which it had originally started, and it dovetailed all the professions together and liberalised them, and ensured more cultivation. In 1512, the Faculty of Arts in the St. Andrews University—the oldest of the Scotch Universities—was a pedagogium not within the University. When the different Scotch Universities were founded, there was always a clear persuasion that professions should be carefully cultivated. There was an interesting statement in the 7th chapter of the First Book of Disicipline of what St. Andrews was then and what it ought to be. There was one college devoted to philosophy and medicine, another to theology, and another to law; and in the unconfirmed charter of Mary, and the confirmed charter to Edinburgh of James VI., it was stated that the University was intended for professions from the beginning; and the lawyers petitioned the magistrates to the effect that the law had got to the dignity of a profession, and ought to receive degrees from the University. Their question was, had any new professions arisen in the world in recent times; and if they had arisen, could the Scotch Universities, without endowments, consent to ignore those professions? Could they, like Oxford and Cambridge, with their large endowments, and the capability of keeping culture with those endowments, refuse to acknowledge new professions and embrace them within their walls? No one could doubt within modern times engineering had become a profession of the first rank. It involved many sciences and the application of sciences, and no one could doubt that it had been raised to the dignity of a profession. Then, with regard to agriculture, there were few arts that embraced more sciences; and if it had been conducted with empiricism, there was the more necessity for putting it on a proper footing. A great demand had arisen lately for technical education, and that must be supplied if England was to retain its position among the nations of the world. The question was whether they would allow polytechnic institutions to arise outside their Universities, or whether they would enlarge their Universities to embrace them within their walls. In Paris, institutions for technical education had arisen round the University, which were granting degrees, and the result was that these institutions were filled to overflowing, while the University was left high and dry, to the amazement of mankind. The Paris University had lost its position by not granting these degrees, but allowing the polytechnic institutions to give them. The University of Zurich also did not see that it must accept the professions that were rising; and what was the consequence? Polytechnic institutions had arisen to take its place, and the University was nowhere. There had lately been several blue-books issued on scientific instruction. One came out last year from the Science Instruction Committee of the House of Commons, and there were several very significant facts in it. Evidence was given of the Establishment of a school of applied sciences outside Dublin University to give degrees in engineering, agriculture, and various applied sciences, and it was stated that the Privy Council had determined to establish a school of science in Edinburgh in connection with the Industrial Museum. They must take care that they did not repeat Zurich over again. If the Government were to grant degrees for technical subjects to new professions that were rising, where would their University stand? The Industrial Museum had always been on admirable relations with the University of Edinbugh, It had given them access to its collections for instruction, and there was a physical bridge of connection between the buildings. The University, seeing that it depended upon the people, and not upon large endowments, and was most sensitive to the wants of the people, should recognise these professions, and by all means develope technical instructions."

Professor Mason seconded the motion. Universities, if they were to continue powerful, if they were to continue vital in the communities where they existed, could only do so, and ought only to be allowed to do so, when they adapted themselves to new and important exigencies as they arose. No exigency at the present moment, he believed, was more important than education in the round of applied sciences. There was a huge education going on at present, and becoming more and more organised, interesting many of the most eminent men of this land—interesting them so that they were munificently giving large sums of money to prove that they felt that the interests of our country were largely connected with increased technical education. This huge education was going on, and would be organised more and more; and the question was—Was it a thing to be organised apart from our Universities or in connection with them? If it was organised apart from the Universities, the result would be what had been pointed out, that there would be in Edinburgh probably a school or institution of practical science, standing side by side with our University. He did not think a department enough, but that they ought to have a new Faculty of applied science, seeing that education was going on in a new direction, that there was in the country a higher demand for proficiency in all departments—if their University would recognise these, and do what it could to confer these degrees, the result would be, in the first place, great increase of prosperity to the University, and, in the next place, an improvement in that technical education itself by the association with it of what they called the higher culture; but if it did not recognise them, a sucker would be attached to their University which would draw out of it a great deal of its strength and vitality. (Applause.)

Mr. Gibson moved that the motion be not adopted. He thought that they were proposing to put the wrong thing first. They were getting the degrees first, and after that getting the teaching, instead of first getting the teaching to attract the students and then getting the degrees. They should not multiply degrees; they should not institute degrees until they saw that there was full teaching for them. He thought there must be some other cause for the decay of the University of Zurich than the absence of scientific teaching, because the University of Berlin paid little attention to the teaching of the applied sciences, and yet it was one of the most flourishing Universities on the whole continent. There would be room enough for the Polytechnic schools as well as for the Universities even though they should be separate; and if such a school were established in Edinburgh, the result would be not to withdraw scholars from the University, but to attract scholars first to school, who would also attend the University.

Dr. Andrew Wood supported Dr. Playfair's proposition. Agriculture was now really a scientific profession, and few professions required more science than that of engineering. He trusted that this representation would go to the University Court, because, if they stood on their dignity as Universities as opposed to Polytechnic schools, they would be seriously damaged. He was a strong Conservative himself in politics, but the very root of the Conservatism which he professed was to watch the tide of the times and to take advantage of that tide. (Laughter and applause.) Therefore, as a Conservative in relation to that University, he supported the motion.

Dr. Thomas Smith seconded Mr. Gibson's amendment. Their degrees of Doctor of Science and of Bachelor of Science seemed to him sufficient to meet the whole want; and he feared any rash innovation. It appeared to him that this was a case in which they might take a leaf out of the book of Dr. Andrew Wood's Conservative party before they were educated, and "let wellalone." He would like that greater attention should be called to their science degrees. He did not think these degrees had been taken sufficient advantage of, and he believed that if they were more largely taken advantage of they would supply the want that was felt.

Prof. Crawford said the main thing to be aimed at was to obtain an endowment of additional professorships in connection with the University; and the true way to obtain that was to obtain the degrees, and then apply to have the staff of Professors increased.

Professor Balfour said what they wished to do was simply to make the existing Chairs available for degrees in agriculture and engineering.

Professor Calderwood, sympathised with the opinion that there ought to be no degrees granted unless they had sufficient teaching power. It was not intended that the proposed det grees should be at the vote of any one Professor, As to the question whether within or without the University they ought to have such training, he asked whether, if they had within the University proper training in mathematics, natural philosophy, and engineering, there was any need that they should have outside the University, provided by public funds, teaching covering exactly the same ground ? On the other hand, if they had, partly in the Faculty of Medicine, and partly in the Faculty of Arts, provision for proper training in agriculture, was there any need that there should be a further provision of public funds in order to have precisely the same teaching repeated outside the University ! He thought that to put these questions was to answer them, and that the General Council would very readily accept the proposal for the institution of the degrees referred to in the motion, and very readily reject all that had been said against the motion.

Rev. K. M. Phin said, that yesterday in the University Court, which he was sorry to say had not yet opened its doors for the public press, they had listened to a long argument in favour of a change in the constitution of the University by the admission of individuals who were not of their sex as students within the walls of the University. The example of the University of Zurich was then brought forward in order to induce them to agree to the proposed change ; but it now turned out, that the University of Zurich was one which they ought not to regard as entitled to set them an example in anything connected with education.

A show of hands was then taken for, and against, Dr. Lyon Playfair's motion, when the motion was carried by 38 against 4 votes.

INSTALLATION OF THE CHANCELLOR OF THE EDINBURGH UNIVERSITY.

The formal installation of the Right Hon. the Lord Justice-General as Chancellor of the University of Edinburgh, took place with great *èclat,* and the ceremonial of conferring degrees was proceeded with. Honorary degrees in divinity and laws were also conferred. The members of the University Court and the gentlemen selected to receive honorary degrees were attired in academic robes, as were the graduates who appeared to have their degrees conferred upon them. The chair was occupied by Principal Sir Alexander Grant, who was accompanied to the platform by the Lord Justice-General, Chancellor of the University; Dr. Lyon Playfair, M.P. for Edinburgh and St. Andrews Universities ; Mr. David Milne-Home, Bailie Russell, and Bailie Fyfe, Curators ; Mr. E. S. Gordon, Q.C., Assessor for the Chancellor ; Mr. Alexander Nicolson, Assessor for the Rector; Rev. K. M. Phin, Assessor for the General Council ; Professors Kelland, Blackie, Fraser, Calderwood, Tait, Masson, Wilson, Oakley, Crawford, Liston, Stevenson, Lorimer, Muirhead, Macpherson, Maclagan, J. Stuart, Tytler, Balfour, Bennett, Turner, Crum Brown, Sir J. Y. Simpson, Christison, and Spence ; Dr. Moir, President of the Royal College of Physicians ; Mr. Campbell Swinton, Sir David Baxter, Bailie Cousin, Colonel Davidson. The gentlemen who were to receive honorary degrees also accompanied the Chancellor and Principal to the platform.

The following received the honorary degree of LL.D. :— Dr. Henry Acland ; Matthew Arnold ; Professor Bain ; Colonel J. A. Ballard, C.B. ; Andrew R. Clark, Esq., advocate ; E. S. Gordon, Esq., Q.C. and advocate ; Lyon Playfair, C.B., M.P. ; T. Collyns Simon, Esq. ; Professor Swan ; Sir W. Thomson, D.C.L. ; and Sir Charles Wheatstone, F.R.S. The Chancellor then delivered his Inaugural Address, which occupied more than an hour.

The *Conversazione.*—The installation was further celebrated by a brilliant *conversazione* the same evening, in the Library Hall of the University. Visitors were received by the Principal and Professors, and the entertainments provided in all departments of science were worthy of the occasion. We regret that space forbids our mentioning others than the Physiological Section, ably conducted by Dr. Hughes Bennett.

◆

Notes on Current Topics.

Sanitary Commission.

This Commission has been entirely reconstituted. We cannot, however, feel that it is such as it should be. It is a decided step backwards. The medical men on the Commission are reduced from seven to five, Dr. Rumsey and the Rev. S. Haughton, M.D., being omitted. No greater blunder could have been committed, except the other that appears in the same act, viz.—that the city of London is altogether to be excepted from the enquiry. If any good is to be done, it cannot be by piecemeal enquiry, or by the substitution for medical men, eminent as sanitarians, mere lawyers, lords, or members of Parliament.

The Late Dr. Dunglison.

The learned author of the "Dictionary of Medical Science" died lately at Philadelphia, where he had lived since his retirement. Robt. Dunglison, LL.D., M.D., was a native of England, and his medical education was conducted in London, where he actually began practice. In 1824, Jefferson, ex-President of the United States, invited him to a professorship in Virginia University. He was promoted in 1836 to Jefferson College, Philadelphia, where he occupied the chair for the remainder of his career. In England he is most known by his great dictionary.

A Veteran.

The death is announced of Dr. J. Heriot, who had served on the medical staff of Sir John Moore in Sicily, and then under Wellington till the close of the great war. He died at Brighton at the age of eighty-five, having been appointed assistant surgeon in the army sixty-five years ago. Few of his *confrères* of that time can survive.

Female Doctors.

A curious discussion took place at the meeting of the Edinburgh University Court, which does not appear in the official proceedings. An appeal was made against a resolution of the Senatus Academicus to admit Miss Blake to some of the medical classes. A very full discussion of the questions involved ended in the following resolution :—

> "The Court, considering the difficulties at present standing in the way of carrying out the resolution of the Senatus as a temporary arrangement in the interest of one lady, and not being prepared to adjudicate finally on the question whether women should be educated in the medical classes of the University, sustain the appeals, and recal the resolution of the Senatus."

The Societies.

The several medical societies of the metropolis continue their activity, so as quite to steal a march on the journals.

At the Medico-Chirurgical, Dr. Barnes read a paper on operations for chronic inversion of the uterus, giving an account of a case successfully treated by a new plan. Dr. Protheroe Smith, Mr. Brooke, the President (Dr. Burrows), and Sir J. Y. Simpson, of Edinburgh, who was present that evening, took part in the discussion. A case of spontaneous cure of hydatid cysts, by Dr. Charles Kelly, was communicated. This produced remarks by Dr. Charles Drysdale, Dr. W. Ogle, and Dr. Hill, to which Dr. Kelly replied.

At the Clinical Society, Dr. Broadbent has brought forward manganese and nickel as remedies for anæmia and chlorosis. Dr. Greenhow has related a case of tabes dorsalis, which has been reported on by Drs. Buzzard and Moxon. Mr. Holthouse has related a case of sub-glossitis.

At the Epidemiological Society, Dr. Dickson, of Constantinople, brought forward the history of the last epidemic of cholera in Persia. He said that a department of public health has been established in Persia.

The Medical Society of London has had the subject of population brought before it in an able paper by Dr. Routh, on "The causes which lead to the unproductiveness of marriages, considered from a national point of view." The author dwelt at the close on some points of a practical kind in reference to sterility, but it cannot be doubted that many of the larger questions started will not be suffered to rest, but will lead to much discussion.

On Monday last, the paper of the evening at the Medical Society was by Dr. Hughes Bennett, of Edinburgh, on Pneumonia.

Contagious Diseases.

The Bill for extending the Act for the Prevention of Contagious Diseases to the metropolis, of which Marquis Townshend is sponsor, contains a very objectionable detail. It proposes to restrict the choice of medical inspectors to Poor-law medical officers. Now, however excellent a body of men these may be—and we have often urged their good qualities—it cannot be supposed that they aspire to any pre-eminence in this speciality, nor that they are possessed of exclusive knowledge on any point. We should rather argue that they have already plenty to do, and that their duties are incompatible with the proposed new ones. We have not space to enter into the general merits of the Bill, but so absurd a provision must not be suffered to pass.

Pogonotrophy.

Progressive Liberalism is about to be developed in a new direction, and free trade in hair has been declared by Mr. Childers. It would appear as if, at haphazard, the Admiralty has fallen upon a really useful reform, for they are about to issue a manifesto in favour of beards, and in a couple of months the British sea lion will appear in all his glory, instead of in the form of a trimmed poodle, as heretofore. It need, perhaps, have hardly taken all these years for their lordships to appreciate the comforts of a full and warm beard in the face of a bitter gale or driving sleet; and the miseries of blunt razors, a two days' growth, cold water, and a rolling ship. Had Lord Byron been a true sailor, he would certainly never have propounded his query as to whether women or men were most happy—whether 365 shaves were not worse than one lying-in.

Another Case of Prolonged Fasting.

A girl of Ulverston named Addison, eleven years of age, is declared to have gone into a sort of trance last October. In January she gained consciousness for a few days and talked of having had interviews with people in heaven. It is stated that no nutriment has been taken for the last three or four months, not even fluids. The limbs are rigid, and the only sign of life is the movement of the chest. It is not improbable that the public will be regaled with numerous similar stories during the next few weeks.

London Pauperism and the Poor-law Board.

We are glad to see that our predictions as to Mr. Goschen's ability to occupy his office are being fulfilled. He spoke most decidedly to a deputation of Clerkenwell Guardians last week, and assured them that with pauperism increasing at such a rate, although the Guardians only wanted to be let alone he would not like the responsibility of letting them alone, and he should do his best to keep down the expenditure. All the talk about "centralization" and the sacredness of "local self-government" was put aside as irrelevant; and altogether the President of the Poor-law Board clearly showed that he had a will of his own, understood his duty, and was not to be badgered. This is a hopeful sign.

Coal Superseded.

Those who expressed so much alarm at the probable exhaustion of our coal fields may be glad to hear that creosote, so familiar to the druggists, is being tried as a fuel with considerable success. At a sugar refinery in Spitalfields, 1,000 gallons of creosote oil are daily consumed in heating two furnaces of 140 horse-power; 220 gallons, at a cost of one penny a gallon, are said to be equal in heating power to two and a-half tons of coal, and 1 lb. of the oil will evaporate 13 lb. of water, whereas 1 lb. of coal will only evaporate 7 lb. of water. The new fuel is far less offensive than any other kind, as it gives off neither smoke nor smell. The creosote flows from a cistern through a pipe into the furnace, where it comes in contact with red-hot coke and brick, ignites, and burns fiercely with a pure white flame. The combustion leaves no residuum. No stoking is necessary, so the stoker's wages are saved.

Pauperism in the House of Lords.

The difference of opinion evinced in the debate on Pauperism in the House of Lords shows how much remains to be said and done, and how far we are from an ideal knowledge, much more prevention. Lords Houghton, Granville, Overstone, Grey, Carnarvon, and Redesdale all differing in opinion, but all evincing deep interest in the subject, is a sight that should cause all persons to reflect further. The denial by Lord Overstone of any necessity for extraordinary measures, though in opposition to an immense array of evidence and to the popular belief, was thought worthy of serious consideration by his compeers; and the view of Lord Grey that *local* not *general* congestion of the labour market was the cause of all the evils is one that is supported by numerous facts.

The Health of Dublin.

In the Dublin Registration District, which has a population of 314,409, the births registered during the last week amounted to 192. The average of the years 1864 to '68 was 166. The deaths registered were 188. The average was 174. Eight deaths from scarlet fever were registered during the week. The deaths from fever amounted to 9, viz., 5 from typhoid or enteric, 3 from typhus, and 1 from "fever." A female, aged 16 years, and a male, aged 18 years, died from cerebro-spinal meningitis. Measles proved fatal in 2 instances. Forty deaths resulted from bronchitis, and 2 from pneumonia or inflammation of the lungs. Paralysis proved fatal in 7 instances, and apoplexy in 2. Diseases of the heart caused 7 deaths, and diseases of the liver 5. One death resulted from diabetes, 2 from nephria or Bright's disease, and 1 from kidney disease, unspecified. Thirty-one deaths were referred to phthisis or pulmonary consumption, 3 to mesenteric disease, 3 to hydrocephalus or water on the brain, and 3 to scrofula. Cancer was the cause of 7 deaths.

The *Pall Mall Gazette* has inserted a letter from "An In-patient of a London Hospital," complaining that no part of Lord Seymour's legacy has yet been paid. They managed this affair better in Paris, but we suppose the lawyers of England must have their dues.

This evening (Wednesday), the forty-first anniversary festival of the Royal Free Hospital takes place at the City Terminus Hotel, Cannon street. The Lord Mayor will preside.

Charing-cross Hospital festival is fixed for the 12th May, when W. H. Smith, Esq., M.P., has consented to preside. The Hospital for Sick Children is to hold its festival on May 14th, Sir J. D. Coleridge, M.P., presiding.

Dr. Cobbold, F.R,S., will deliver the course of twelve Swiney Lectures on Geology and Palæontology, at the Royal School of Mines, on Monday and Saturday evenings, commencing Saturday, May 1st. Admission is free, and ladies are invited to attend.

The *California Medical Gazette* informs us that in San Francisco there have been during the month of March some very fearful cases of scarlatina. Children have been cut off in a few hours from the intensity of the blood poisoning—the symptoms being vomiting, purging, and collapse, without, or with only a partial appearance of the eruption.

We commend the following facts of which we are reminded by the *Australian Medical Gazette* to the vaccinomaniacs who have recently devoted themselves to the obstruction of the law and the propagation of smallpox :—

When vaccination was *voluntary*, the deaths in London were 16 in the 1,000 of the deaths from all causes, and in Edinburgh 19; but in Glasgow the number was as high as 36, Limerick 41, and in all Ireland 49.

But in those countries where it was *compulsory*,—as, for instance, Westphalia—only 6 in the 1,000 died, and in Lombardy and Venice 2 in the 1,000. In France only 1 in 100 of those attacked with small-pox died; and in Austria, instead of the deaths being 1 in 17 of the deaths from all causes, they diminished to 1 in 7,017.

Serious disturbances have lately taken place in St. Petersburg at the Medical Academy and spread to the University and Technological Institution, as well as to the University of Moscow, in consequence of which the lectures have been suspended in some of these establishments. The cause of these disturbances was a quarrel between the medical students and the secretary of the Academy. One of the students had been obliged to defer his examination, which ought to have taken place in the month of May, to the month of September, but as no public examinations are held in this month the student was privately examined by the professors, who provided him with testamurs. These testamurs the student presented to the secretary, who unfortunately lost them. On the opening of the winter courses the student was not transferred to a higher course, as he should have been, and on inquiring the reason of this, he was answered that his papers had not been received. The whole body of students on this determined to have justice done their comrade, and sent a deputation to the secretary to demand an explanation of the matter. The secretary of the Academy did not reply to this demand, but only said that he did not recognise their deputation. Later, however, the secretary sent the students a letter of apology, but unfortunately it came too late to pacify their anger and indignation, which was now at its height. Breaking through all restraint during a lecture, the students made such a tumult and riot that the police were obliged to be called to restore order. Many have been arrested and sent to the fortress, where they are now awaiting judgment.

Correspondence.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You will much oblige me by directing the attention of candidates for medical appointments in the Royal Navy to an important alteration that has been made in the regulations.

In those issued by the Lords of the Admiralty on May 7, 1867 (sect. 9), it was announced that "a favourable consideration will be given to those who have obtained the degree of M.D. from any University in the United Kingdom."

The President and Fellows of the King and Queen's College of Physicians remonstrated against this announcement, as it implied that the qualification given in Medicine by a College of Physicians was inferior to that given by *any University* in the United Kingdom; and as it confounded together all Universities—those requiring degrees in arts previous to graduation in medicine, and those not requiring degrees in arts.

In addition to a written remonstrance, Sir Dominic Corrigan, Bart., and Professor A. Smith had an interview, in June last, with Lord Henry G. Lennox, then Secretary to the Admiralty. The result has been, that the paragraph has been withdrawn from the recent Regulations of the Admiralty, issued on the 4th November, 1868, which now place fairly on a level all who pass the examination for the Navy, without regard to their place of education or the corporation from which they have obtained their qualification.

I am, Sir, your obedient servant,
James Little, M.D.,
Fellow and Registrar, K.Q.C.P.I.

Dublin, April 24, 1869.

Literature.

Journal of Anatomy and Physiology (Second Series No. II and III). Conducted by Professors Humphry and Turner.

In the two numbers of the *Journal of Anatomy and Physiology* which are before us, the editors have, we think, fairly earned the support to which honest labour is entitled, and we hope that a just appreciation of the special object of this journal, as well as its special merits, will induce our workers in these branches of knowledge to contribute to its pages. We are inclined to say this because it should be, and doubtless is, the endeavours of the editors to make the journal of sufficient interest to attract the attention of the medical public generally, and not that of a comparatively small number of science-workers; still less should it become a mere compendium of isolated facts and a record of dissection, to be shelved as soon as received, and to be taken down only for reference if at all.

In No. II., we have to notice a tendency to what is certainly an excess of dissection, records without a balance of interest in the other papers. In No. III., however, the papers are of unusual attraction throughout, and we trust this number is more truly a type of what may be expected of the journal than the former.

Drs. Crum Brown, and Fraser, communicate a paper upon a very important subject, and we trust will not let their labours in this direction stop here. Their object is to trace the connection between chemical composition and physiological action, and they examine carefully the physiological action of the salts of the ammonium bases derived from strychnia, brucia, thebain, codeia, morphia, and nicotia. They show that chemical addition produces some important modifications in the action of these poisons—that for instance, iodide of methyl-strychnium acts not as strychnia, but as curare—acts not by inducing a morbid excitability of the spinal cord and muscular system, but by paralysing them; that not only iodide but sulphate of methyl-strychnium acts in this matter, and that speaking generally, when any nitrile base possesses a strychnia-like action, the salts of the corresponding ammonium bases have an action identical with that of curare. There is no doubt that this is an important observation, and that these new substitution compounds being much more definite in composition, and being much more readily obtainable, will be of great value as substitutes for that substance, curare. They also point out the fact that the action of morphia is not simple, but that in addition to the soporific action it exacts a stimulant effect on the spinal cord; soluble salts of methyl-morphium possess a narcotic but no spinal-stimulant action; they may, therefore, prove advantageous substitutes for the salts of morphia especially when given to children.

Apropos of this subject is Dr. Beigel's communication upon the action of curare and of an African arrow poison. He has used subcutaneous injections of the curare amounting to 1-3 grains at a time in cases of epilepsy, producing specific effects; but it does not appear that any special or permanent benefit resulted.

In the paper by Mr. Wood, which opens the third number, there will be found a careful and interesting examination of the true relations of the aorta and mediastina in the human body. We are glad to see this, for there has hitherto been so much discrepancy in the limits assigned by various text-books on anatomy to these all-important parts that we think Mr. Wood has done good service by calling attention to those inaccuracies and pointing out where the error lay. He divides the thorax by a line drawn horizontally from before backwards through the lower part of the first piece of the sternum, to the body of the fourth dorsal vertebra, and passing ultimately out through the lip of the fourth spinous process of the dorsal region. This line divides the thorax into an upper fifth and a lower four-fifths, the lower comprising the three mediastina but the upper or cervico-thoracic portion being above the middle and posterior mediastina and forming the root of the neck; in this upper part, therefore, only the anterior of the three mediastina is represented, and the line marks the upper limit of the aortic arch.

Another line drawn through the third piece of the sternum horizontally backwards through the spinous process of the sixth dorsal vertebra corresponds with the origin of the aorta and pulmonary artery from the heart. Mr. Wood also insists very strongly that the arch of the aorta terminates at the lower border of the fifth instead of the third as is generally vertebra stated. We have one very serious fault, however, to find with this communication. In a paper which professes to correct the errors of others a little care ought to be bestowed in order to make the diagrams which must be constantly referred to for explanation of the text, themselves free from error. We can hardly suppose the irregularity in the branches of the aortic arch and the great separation between the base of the heart and the diaphragm were intentional. These apparent errors may, to many, make it difficult to imagine that the diagram has been taken from an actual vertical section of the subject, and may unfortunately weaken the influence this communication ought to have.

Mr. Lee has a paper upon the ciliary muscle in certain birds, fish, and quadrupeds, and gives a short account of that structure in the fowl, cod, cat, and the owl and falcon, as seen by ordinary dissection under water or spirit. There is not enough, however, to warrant any conclusions being drawn as to the condition of that muscle in the different classes of animals, and no attempt is made to particularize its function, though Mr. Lee does not credit the usually received views in that respect.

After a very careful and elaborate paper by Professor Macalister upon the homologies of the atlas and axis, there follows one by Dr. Chiene, of Edinburgh, upon a curious case in which there was complete obliteration of the cœliac and mesenteric arteries. The points of practical importance in this case are to be found in the fact that all the abdominal viscera instead of receiving their blood supply through their ordinary or peritoneal course, received it by means of extra peritoneal vessels; the stomach, liver, spleen, and duodenum being supplied from the left lower intercostals and left renal and supra-renal, the remainder of the intestines by the internal iliacs, except the cœliac and ascending colon which received blood from the last dorsal artery of the right side. In the employment of depletory measures therefore to different parts of the abdomen a satisfactory explanation is apparent in the readiness of communication under certain circumstances between the skin and the engorged vessels of the inflamed viscus, and the emptying of the former being attended with partial emptying of the latter.

Messrs. Mosely and Ray Lankester drew attention to the unsatisfactory state of dental nomenclature, and the consequent difficulty in denominating teeth with any accuracy, and they propose what appears to be a very simple arrangement and one sufficiently philosophical and sufficiently practicable to warrant adoption. It is founded upon the development of the upper jaw—certain teeth belonging to the præmaxillary and others to the true maxillary portions. These latter are divided into an anterior and a posterior series corresponding with canine and præmolars on the one hand, and with the true molars on the other. Similarly, the teeth of the lower jaw, or the mandibular group are arranged in a median, anterior lateral, and posterior lateral series, corresponding with the series of the upper set of teeth. We must again call attention to the obvious error which has been allowed to stand in the diagram, where the words anterior and posterior are substituted for one another. The authors of this paper point out a curious fact in the dentition of the common mole —viz., that it is the only placental mammal having eight præmaxillary teeth.

Passing by an account by Professor Humphry of the dissection of a case of Ectopia Vesicæ, upon which he makes a few suggestions as to the mode of origin of such malformities, we come to a very interesting paper by Dr. Dickinson, upon the changes in the nervous system, which follow amputation of the limbs. Dr. Dickinson's researches into the function of the cerebellum, it will be remembered, led him to the conclusion that that organ had a special influence over the lower limbs, and he in consequence examined carefully the brain after amputation of one or both lower extremities, in the expectation of finding atrophy more or less marked in the cerebellum. He was, however, driven to the conclusion that no loss of weight, or appreciable change in structure followed in this organ, but he now records the appearances which different parts of the spinal cord present under these circumstances. The nerves of the stump atrophy, although from the increased development of fibrous tissue the naked appearances are not altered; the nerve roots waste, but the posterior or sensory one particularly; and a remarkable shrinking takes place in the posterior column of the cord on the side of the mutilation, attended by a condensation of areolar tissue. These results are interesting, but it does not appear quite evident to him why the posterior columns and roots should become more atrophied than the anterior. We should, however, be inclined to expect such a result; for the functional activity, and therefore, *cæt. par.*, the nutrition of sensory nerves, is excited and supported by stimulation from the periphery, whereas, that of motor nerves is from the centre.

Professor Cleland, of Galway, in a short paper combats the view, which has hitherto been held upon the authority of Mr. Toynbee, that the Eustachian tube is opened in swallowing, and remains closed at other times. He states that the levator and tensor palati must each tend to close the tube, owing to the pressure of the whole body of the muscle below the tube, their fixed point above being the fibrous bone for the levator, and the sphenoidal spinous process and internal pterygoid plate for the tensor. The explanation of Professor Cleland's views are not much helped by the sketches or diagrams accompanying the paper, these, in fact, serve rather to mislead.

Professor Turner communicates a paper on the skull of a new species of arcto-cephalus, and Dr. McBain on that of an otaria; and these are followed by some interesting chemical papers by Professor Heynsius of Leyden.

Dr. Allen Thomson, of Glasgow, examines carefully the ossification of metacarpal and metatarsal bones, and argues from the inconstancy of the epiphyses in number and position in the animal series, that we must distrust their position as the ground for homological distinction between the first and the other metacarpal and metatarsal bones.

This volume "ends with a most valuable and interesting reprint of the Idea of a new anatomy of the Brain," which was submitted for the observations of his friends by Sir Charles Bell; and to this are added selections from letters of th same distinguished author. It is written with the energy and clearnesss which eminently distinguished him, and we are pleased to see the hitherto almost unpublished paper, which created so great a revolution in the anatomy of the brain which, in fact, attempted to substitute a philosophical study for a confused jargon of names, laid before the scientific world by the enterprising editors of this paper. In the extracts from his letters which are here given, we have a view of the enthusiasm with which he pursued his subject, and, side by side with this, little touches of feeling and glimpses of the inner life of a man whose genius has shed a lustre on the scientific world; and these glimpses are pleasant enough to make us wish to see and know more.

◆

Medical Gleanings.

EXTIRPATION OF THE UTERUS FOR COMPLETE PROLAPSE.

Prof. Langenbeck, of Hanover, has recently performed this operation upon a woman 48 years of age, who had suffered from prolapse since the birth of her first child eighteen years previous. She had borne nine children since then. The result was a good one. The patient removed the ligatures herself from the eighth to the tenth days. The operation was performed on the 15th of May; on the 29th she left her bed; and on the 31st she took her first walk in the open air.—*Memorabilien.*

TYPHOID CUTANEOUS SPOTS.

The occurrence, in conjunction with an unusally copious roselar eruption, of another one of a yellowish-brown colour of the size of a two-dollar piece and over, is described by Zulchaur (*Berliner Klin. Wochenschr.*) The latter spots run into one another. They were only observed in very severe cases, which in the first, or in the commencement of the second seven days' period, terminate in death.

PHOSPHATES OF THE URINE INCREASED BY MENTAL EXERTION.

Dr. H. Byasson, in a little pamphlet entitled, "Essay on the relation which exists under physiological conditions between the Cerebral Activity and the composition of the Urine," furnishes a variety of experiments instituted upon his own person which confirm, in an exact manner, the popular belief of an increase in the phosphates of the urine as the result of mental exertion. Dr. B. commences by detailing his method of analyzing the urine with reference to attaining the greatest amount of exactness in determining the constituents quantitatively. For twelve days he made daily examinations of his urine, taking no special precautions as to his diet. For nine days he confined himself to an exclusive diet of bread and water. Under the latter regimen he maintained his weight, and enjoyed ordinary health. He gives details of his daily occupations while performing these analyses, alternating days devoted to study, with days spent in muscular exertion, or in complete bodily and mental activity. While indulging in a mixed diet he found no special variations in the composition of the urine, as the result of his occupation, but when confined to a simple diet of bread and water, he found that when the brain was in a state of activity, there was a more abundant production of urine, and the simultaneous appearance in the urine of urea, and the alkaline phosphates and sulphates in increased proportions. When the muscular system was chiefly called into action there was an increase in the amount of urine, and the simultaneous apparition in the urine of urea, uric acid, and chloride of sodium. So that, provided a man should be subjected for three days to a uniform diet, and placed under nearly similar external circumstances, it would be possible to determine, by anylysis alone of urine which day had been passed in repose and which had been spent in physicial or mental exertion.—*Medical Record.*

EXPERIMENTAL RESEARCHES ON THE ACTION OF QUININE.

Dr. C. Binz has been making an experimental study of quinine, with a view of discovering its mode of action. And he selects for experiment some of the infusoria developed in vegetable infusion; employing the neutral chlorohydrate of quinine, soluble in sixty times its volume of water. He finds that this salt of quinine, even in weak solution, destroys these infusoria much more promptly than much stronger solutions of salicine, morphine, and strychnine: showing there is some peculiar antiseptic action different from that of other vegetable alkaloids. From these low animals, he proceeds higher up the scale; and eventually examines the effect of quinine on the blood, He fed two kittens with half an ounce of milk, and then subjected one of them to several subcutaneous injections of quinine. On examining the blood of these animals under the microscope, some time after, he found a marked diminution in the proportion of white globules on the part of the one which had been subjected to the action of the quinine. Before the experiment, this animal's blood showed more white globules than the other, 294 : 214; after the experiment, the proportion was enormously reduced to 17 : 344. Dr. Binz believes that subcutaneous injection of quinine retards the development of inflammation and moderates its effects if it has been developed. Dr. Binz accepts the views of Dr. Salisbury, regarding the alga of intermittent fever, and explains the therapeutic effects of quinine in that disease, by its action in his experiments upon the lower organisms. He believes the doses of quinine usually given to be too small, and suggest the use of the chlorohydrate in preference to the sulphate on account of its greater solubility.—*Allg. Med. C. Zeit.*, *Berlin Kl. Woch.*,

THE MICROSCOPIC COMPONENT PARTS OF VACCINE LYMPH.

Fresh lymph from normal developed cow-pox, which for the naked eye is of transparent appearance, shows, examined by the microscope, beside the incidental admixture of small particles of duct, débris of epidermis, blood-corpuscles and coagulated fibrin as well as pus-corpuscles, which have been detected by former observers, as a number of peculiar grand cells, innumerable free granules, and punctiform molecules, of scarcely measureable size. The granule cells contain occasionally some more solitary, somewhat larger, round granules; the number of granules in the cells amount from three to twenty and to more; sometimes they cohere so intimately, that it appears as if they were in a state of multiplication by self division. These structures are found in the cow-pox as soon as they contain some lymph; after the ninth day the pus-corpuscles become more numerous. By admixture with distilled water the above described structures do not undergo any change; the granule cells remain on the filter, whilst a number of granules and molecules pass through. The filtered lymph does not lose it efficacy. The coagula which were sometimes observed in lymph which has been kept for a time, consist principally of the above structures, while no traces of them are visible in so-called wild lymph, which is not meet for the production of genuine cow-pox. Crystals are found in lymph, whether in its drying or in its decomposing state. In the writer's opinion, the granule cells and granules which he observed in his experiments, are the bearers of the contagion. Only such lymph, which contains them, can be applied for the successful production of useful vaccine matter, whereas such lymph which contains already acicular and fassicular crystallizations, has no effect whatever. He believes that the fungoid growths and fungi which are found in diluted lymph, are of no consequence in regard to producing vaccine matter. The examinations of lymph taken from variola and varioloid, gave the same results as those which are apparent in the lymph from cow-pox; they even were better to be seen in lymph from variola, the granule cells and granules of larger size, and more conspicuous. The examinations of the blood of small-pox patients, as well as the air of the small-pox wards, did not give any positive result.—*Philadelphia Medical Reporter.*

POISONING BY NITRO-GLYCERINE.

In a restaurant where many young men are wont to dine, there stood one day upon a table a half-filled bottle, which one of the servants mistook for the undrunken portion of a bottle of wine that had been ordered, and he poured himself out half a wineglassful and drank it. The disagreeable taste, the burning in the mouth and œsophagus, retching and vomiting which immediately ensued, and the severe pain in the stomach, showed that he had drunk something else than wine, and it was soon discovered that it was nitro-glycerine, that had just been placed there by a party who intended to make some use of it. The vomiting which ensued rendered the administration of an emetic unnecessary. The patient was given almond emulsion with opium, and demulcents. The result was a favourable one. Terrible pain in the stomach, with loss of appetite and intense headache, was endured for three days, after which the patient recovered entirely.—*Memorabilien.*

EMPLOYMENT OF PHOSPHIDE OF ZINC IN MEDICINE.

M. Vigier and Dr. Curie have recommended the use of phosphide of zinc in cases where the administration of phosphorus is indicated. This substance is a grey crystallized body, perfectly definite in composition, unaltered by moist air, and keeping well, either in powder or in pills; but nevertheless easily decomposed in the stomach, and capable of exercising an action on the system identical with that produced by phosphorized oil. Phosphide of zinc is selected in preference to the other metallic phosphides, because it is at once perfectly stable, and easily decomposed by weak acids. Even lactic acid attacks it, evolving phosphoretted hydrogen; according to Messrs. Vigier and Curie this explains the action which occurs in the stomach. Phosphide of zinc is prepared by passing the vapour of phosphorus over zinc heated to ebullition, in a current of dry hydrogen.

The authors administer it in doses of one milligramme (0·015 grain) several times a day. It is given either in the form of pilules or of powder.

REMARKABLE CASE OF PROSTATIC CALCULI.

Dr. Paulicky gives an account of a prostate removed from the body of an invalid of the Hamburg garrison, 73 years of age, which felt exactly like a gall bladder distended with calculi The urethra was, in fact, surrounded by a large smooth-walled, sinuous cavity, which contained the stones. It occupied almost all the lower half of the organ, only about two lines in thickness of the parenchyma remaining; and the calculi, instead of being embedded in this, were contained in the cavity so formed close in contact with each other. The upper half of the gland retained its ordinary appearance, containing only a few concretions. There were counted two hundred and forty calculi, the largest one measuring six lines in diameter, and weighing three days afterwards 2·7 grammes. Two others were nearly as large, and eleven others had a diameter of two lines. The great bulk of the calculi varied in size between millet-seed and lentils. There were also numerous little stones scarcely recognisable by the naked eye. In form and appearance these calculi much resembled gall-stones, but differed from them by their great hardness. The largest stone mentioned above had perforated the urethra.—*Wien. Med. Woch.*

PREVENTION OF PAIN FROM BLISTERS.

M. Bricheteau states that he has found the hypodermical injection of from 5 to 10 drops of a solution of hydrochlorate of morphia (1 part to 50 of water), executed immediately before applying the blister, a most excellent procedure. When the blister is good it begins to rise in from three to five hours, and, as the effect of the morphia lasts for six or eight hours, all pain is prevented during the process. In some persons, whose skins resist a blister more than ordinarily, the injection may be delayed for an hour after its application. By this means when a blister is applied at night, the patient, so far as it is concerned, may still enjoy his night's rest; and sensitive persons are saved much suffering, as, for example, in the case of the application of blisters to the hypogastric region in young women. The dressing a blister also requires attention. No greasy substance should be applied; but having left as much of the raised epidermis intact as possible, this should be emptied of its serum by a broad clip with scissors, and, after it has sunk down again on the dermis, a thick layer of wadding should be applied. This is to be left on for two days, no other dressing being required. Cicatrisation may also be hastened by the following contrivance:—Cut a good-sized hole in the centre of the blister before applying it, and this central untouched portion great expedites the healing of the denuded zone which surrounds it.—*Bull de Thérap.*

MICROSCOPIC FUNGI AS THE CAUSE OF CONTAGION.

Dr. Lissauer, has made a number of experiments with penicillium, and concludes that fungus is not a cause of contagion, but is an accidental presence. He first found it in vaccine lymph; then he procured some from the surface of a cut lemon, and with this he attempted to produce vaccina in a calf, but without effect. In contradiction to Hallier, he says: "I believe I have shown that we cannot advance pathology by cultivating microscopic fungi from the products of disease; and that, moreover the detected and censured fungus cannot be regarded as the contagium until we have succeeded in producing the disease by art."—*Berl. Kl. Wochenschrift.*

TREATMENT OF PROLAPSUS ANI.

Dr. Schartz advocates for this affection a solution of the ext. of nux vomica, of the strength of one or two grains to the ounce of distilled water. Of this solution he gives six to ten drops every four hours. This is the dose for very small children; to larger children, fifteen drops at the same intervals. Two or three drops should be administered to children at the breast.—*Nashville Journal of Medicine.*

WARM COD LIVER OIL

Dr. Betz finds warm cod liver oil often tolerated when the oil cold cannot be borne.—*Memorabilien.*

MISCARRIAGE WITHOUT PAIN.

Dr. R. S. Kelso, details the following interesting case of painless miscarriage, in the *Chicago Medical Journal.* October 10th, 1867, was called to Mrs. D., pregnant about five months. While engaged in her ordinary household duties, without the least premonition, there was rupture of the membranes, and discharge of the amniotic fluid. 11th. Ordered tinct. ergot in drachm doses, every hour for six hours, but without effect. In the evening I found the os uteri well dilated, right shoulder presenting, with protrusion of the hand and arm, though she had not felt a single pain, but only a weight, or dragging sensation, when she stood upon her feet. Not thinking it necessary to turn, as the fœtus was small, I introduced a finger on each side of the neck, and brought down the head; then with slight traction, and a bearing down effort on her part, it was easily delivered. There was also another fœtus, with breech presenting, which I delivered in like manner, by bringing down the feet. After waiting an hour, I administered chloroform, and removed the placenta, which was so firmly adherent that it was impossible to detach it, except by taking it away in pieces. The lady had a good getting up, and in ten days was able to perform her household duties, not having had a single pain from first to last. I have since attended her in a miscarriage brought on in the same way, but she had a few pains.—*Philadelphia Medical Reporter.*

Medical News.

Waste of Fuel in the United Kingdom.—No less than 104,500,480 tons of coals were raised in 1867—the mineral statistics for 1868 are not yet published—from the coal mines in the United Kingdom; and of this enormous quantity the conjectures of experienced persons would lead us to suppose about one-third was used in fireplaces for the domestic purposes of warming and cooking. If we assume that the average price of coal delivered to the householder is 20s, per ton, the amount expended in that year must have been £34,833,463; and if we further assume the average waste of fuel used for domestic purposes to be equal to a fourth of that which is consumed, there must have been an actual loss amounting to £8,708,373. A little consideration of these figures suffices to show of what great importance is economy in the use of fuel, both in a national and an individual sense. It is deplorable that our mineral treasure should be squandered, and that our wasteful habits should simply entail the diversion of a large sum from its legitimate purpose of promoting the pleasures or alleviating the sufferings and inconveniences of life.—*Westminster Review, April* 1869. Art IV., *Domestic Fireplaces.*

The Public Health.—According to the Registrar General's return last week the rate of mortality in London was 26 per 1,000, while in 13 other large towns in the United Kingdom it was 28. In the metropolis, 2,157 births and 1,595 deaths were registered. The latter exceeded by 75 the estimated amount of mortality, and were more by 45 than the number recorded in the preceding week. The deaths from zymotic disease were 320, the corrected average number being 326. Two deaths from small-pox, 28 from measles, 41 from scarlet fever, three from diptheria, 108 from whooping-cough, 24 from typhus fever, 14 from enteric fever, 17 from simple continued fever, and 21 from diarrhœa were registered. During the last six weeks 480 children have died from whooping-cough, and within the seven days referred to in the report the number of children whose deaths from all causes were recorded was 662. During the week the mean temperature was 55·2, or more than ten degrees above the average.

The President of the Royal Society's Soiree.—On Saturday evening, the second and last conversazione, given by the President of the Royal Society, took place at Burlington House, Piccadilly, on which occasion a numerous company thronged the several rooms. Among the distinguished scientific Fellows, &c., of the Society were Dr. Miller, Dr. Sharpey, Professor Stokes, Professor W. H. Miller, Dr. Carpenter, Mr. Alfred Tennyson, Sir Francis Grant, Mr. Bentham, General Sir G. Pennefather, Sir C. Locock, Sir T. Lawrence, Sir D. Wyatt, General Sir Vincent Eyre, Sir John Rennie, Mr. E. J. Reed, Sir Leopold M'Clintock, Professor Maxwell, Professor Cayley, Dr. Burrows, Professor Williamson, Admiral Ommanney, Mr. Laird, M.P., General Sir G. Lawrence, Colonel Dixon, General Lefroy, Professor Huxley, Professor Tyndall, Dr. Webster, Professor Malden, Professor Owen, Dr. Sibson, Professor Ramsay, Sir N. Madden, Professor Allman, Mr. Spottiswoode, Professor Donaldson, Professor J. C. Adams, Dr. B. Stewart, Dr. Hooker, Dr. Quain, Dr. Odling, Dr. Murchison, Mr. N., North. M.P., Professor Goldstucker, Dr. Bird, Mr. James Rennie, Mr. Tite, M.P., Professor Partridge, Dr. Gilbert, the Earl of Dunraven, the Earl of Mount Charles, Lord Chelmsford, the Earl of Sheffield, the Persian Minister, the Columbian Minister and many others. The several apartments thrown open abounded with objects of scientific interest.

At the Dialectical Society of London, Medical Society's Rooms. On May 5th, Dr. Charles Drysdale will read a paper, "On the Inadequacy of Emigration as a Remedy for Overcrowding and poverty."

Birth in a Railway Carriage.—The *Times* of last Saturday says:—A rather startling incident occurred a few evenings since on the Great Northern Railway. A lady, whose husband possesses a considerable estate in a northern county, feeling herself in an interesting conditioe, summoned to a consultation at the family seat a celebrated London accoucheur. The doctor made the required visit, but the pressing appointments to which he was bound rendered it impossible for him to accede to the husband's urgent request that he would remain with his wife through her confinement. Ultimately, in order to have the advantage of this gentleman's skill, it was arranged that the lady should come to London and take up her residence at the Great Northern Hotel. Accordingly, the parties left home on Sunday last with a local surgeon in attendance. All went well until the train reached Hitchin, when appearances presented themselves which made the medical man anxious to remove his patient from the railway carriage. The exigencies of railway travelling, however, afforded no time for more than a moment's consultation with the guard, and before any decided step beyond the removal of the husband to the next carriage could be resolved upon, the train was again in motion towards London. Between Hitchin and King's cross a "little stranger" was born, and for lack of other swaddling clothes the new comer was carried to the Great Northern Hotel in a copy of *The Times* newspaper. The mother was placed on a stretcher and carried across to the same hotel, where the most efficient attentions were immediately bestowed upon her by Madame Schumann, wife of the manager of the Great Northern Hotel, under whose care both mother and child are doing well.

County Coroners.—Mr. Goldney has laid before the House of Commons a Bill for enacting that county coroners, instead of being elected by the freeholders, shall be appointed by the Lord Chancellor or the Home Secretary. The Bill proposes, also, that every county coroner shall be paid a fixed salary, to be agreed upon with the Quarter Sessions, subject to appeal to the Home Secretary if the parties cannot agree; and that a coroner disabled by age or infirmity shall have a superannuation allowance awarded to him.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The meeting of the College which we announced last week, as to be held for the election of a Councillor in the room of Dr. Mackesy, assembled on Monday last. No less than six candidates presented themselves, enumerated in the ballot list as follows:—Dr. John Morgan, Sir Wm. Wilde, Dr. Kirkpatrick, Mr. Smyly, Dr. Barton, and Dr. Stewart, of Lucan.

The College assembled in force, nearly 100 votes having been polled, and the voting resulted in the election of Dr. Morgan by a majority of 13.

◆

SIR PATRICK DUN'S HOSPITAL, DUBLIN.

The memorial from the Physicians and Surgeons of Clinical Hospitals in Dublin to the Provost and Senior Fellows of Trinity College, to which we alluded some weeks ago, has been, we learn, under consideration of the Board. It referred, as our readers will recollect, to the restriction with which, since the year 1834, has been maintained, that candidates for the medical degrees of the University should attend for nine months at Sir Patrick Dun's. We understand that the Board have adopted the following resolution, and will shortly communicate it as their reply to the memorial.

Resolved,—"That the Board of Trinity College are prepared to recognise for the degree of Bachelor of Medicine certificates of all hospitals in Dublin which shall prove to their satisfaction their willingness and ability to teach all the branches of medicine and surgery, as soon as Sir Patrick Dun's Hospital shall have completed its arrangements for securing the undivided attention of its entire medical staff."

We presume that this resolution is susceptible of interpretation in two respects: Firstly, that the Board of Trinity College will require in recognised hospitals that there shall be wards for the treatment of fever and contagious diseases; and, secondly, that the medical staff of Sir Patrick Dun's who now hold appointments in other hospitals will be expected to confine their services to Sir Patrick Dun's alone.

It may probably be some time before this latter requirement can be complied with; but as the principle of the memorial has been conceded, by the Board, we are satisfied that its practical application will not be long delayed.

◆

NOTICES TO CORRESPONDENTS.

Anti-Vaccinator.—We are not favoured with the name of our Correspondent whom we must ask to take the personal responsibility of his peculiar views.

Cooper.—The College or School will not depart from its system in the direction you indicate, nor will the public departments entertain the proposition. There are, however, many teachers who will, we believe, undertake to do what you propose. Address Dr. Stoney, 80 Lower Baggot street, Dublin.

Professor Huxley's Theory of the Protoplasm.—The criticism has appeared in extenso in the English Mechanic, and is, therefore, declined.

Dr. E. F. Bean, Ashburton.—A new edition of Sir Thomas Watson's Lectures in Medicine will shortly be published by Messrs. Longman, Green and Co.

NITROUS OXIDE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I must ask you kindly to correct a printer's error in my letter last week.

Referring to the cyanosed appearance of the patient while under the influence of Nitrous Oxide, I said that as soon as the inhaler was removed, the colour returned instantly with the *re-oxygenation* (and not the re-organisation) of the blood.

I am, Sir, Yours truly,
J. Dennant, L.D.S., R.C.S.
Dental Surgeon to the
Brighton Hospital for Sick Children.

The Medical Press & Circular.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,
Deputy Inspector-General of Hospitals.

(Continued from page 181.)

HEPATITIS.

Soldiers in India suffer more largely from hepatic inflammation than those quartered in other tropical regions, whether in China or the West Indies. This class of diseases vary much in their rate of prevalence at different stations in that country, and, as might be anticipated, are much affected by seasons; thus there exists a general impression in India, the truth or otherwise of which can of course be readily tested by statistics, that not only is the rate of prevalence of liver disease different in the different Presidencies, but that similar variety takes place in the frequency of abscess in that viscus, and in its depth, and even in the circumstance of whether suppuration occurs in one large cyst or in several small ones. These subjects are ably discussed by Geddes and Annesly.

Various explanations have been given in regard to this difference in the rate of occurrence of the disease under apparently similar circumstances. Hunter[*] mentioned the fact in 1808, but attempted no explanation of it. Davy,[†] more recently, in alluding to it, expresses an opinion that the difference depends, in some measure at least, on the amount of out-door exercise in which the climate permits a soldier to indulge, the prevalence being greatest where the men are least out of doors. Other causes, according to him, include the kind of diet and drink used, confinement in ill-ventilated rooms, continued high temperature, and elevation of the locality above sea level. My own experience does not enable me to express a decided opinion regarding the influence exerted by these circumstances, but I enumerate them here as deserving further attention.

With regard to the season during which hepatitis principally attacks our soldiers in India, I find that of 225 cases of which I have statistics, there occurred 68 between April and June, 71 from July to September, 50 from October to December, and 36 between January and March. The rainy season is thus shown, as indeed might have been expected, to be that during which the disease prevails most generally; and as indicating the near approximation that exists between the occurrence of "liver" and malarious fever, I observe that while an average of 4·66 cases of that affection are shown to have occurred per 100 strength during the period in question, the proportion of cases of the latter was 4·22. It has, moreover, been observed that the periods of their greatest prevalence were nearly alike, fevers having been most numerous in August and September, and hepatitis in these months and July.

If we consider the meteorological conditions that characterise each of the periods first alluded to, they may be briefly characterised thus:—From April to June the temperature is high, but its variations small; the atmosphere is dry, its degree of saturation at its minimum; from the occurrence of storms the atmosphere was in frequent and rapid movement; electricity in a frequent state of fluctuation, and evaporation at its maximum. From July to September the general average height of the thermometer is somewhat less, but the diurnal variations still very small; humidity is at its maximum, the air seldom disturbed by electric discharges, and evaporation at its minimum. From October till the end of December the temperature undergoes considerable decrease, and the daily variation increases; the mornings and evenings are cool and bracing, the atmosphere is less saturated, and its capacity for evaporation greater than in the preceding period. In the succeeding three months—namely, from January to March—a gradual increase of temperature takes place, the daily variations diminish, and the dryness of the air still further increases.

With regard to the period of a soldier's residence in which the liability to hepatitis, as well as the rate of mortality by that disease, are greatest, my statistics indicate that in the first year attacks are relatively rare ; but when they do occur, the rate of mortality is very great. From that time to the fourth year the liability to attack fluctuates, but in an increasing ratio, the mortality being small. In the fifth year the proportion of attacks is not very great, but the rate of mortality by them the largest of any period of which I am in possession of statistics. In the sixth year the number of attacks are far more numerous than in any similar period of Indian residence; but the liability to death by these attacks is less than half as great than it is during the first year of residence in India. From the seventh to the ninth year the liability to attack and to death by the disease fluctuates, but with a downward tendency; both to take a most material rise in the tenth ; the rate of mortality even then, however, is about one-fourth of what it was in the fifth year, and liability to the disease nearly equal to what it was in the sixth. To prosecute this inquiry further is now rendered unnecessary, as soldiers are unlikely to continue with their regiments in India beyond ten years.

---

[*] Diseases of the Army, page 304.
[†] Diseases of the Army, page 130.

That this form of disease may, and often does, occur from long-continued exposure to what is called "malaria," and without the intervention of any definite *exciting* cause, is now pretty generally allowed. It is also understood among army surgeons that repeated attacks of intermittent fever sooner or later end in organic disease of the liver, and that, therefore, removal of the affected person from the local influences to which he owed the primary symptoms should take place before the tendency to fever has become habitual. In many cases, removal to the hills will be sufficient; but in others, departure from India is alone effectual. I am aware that the dependence of the disease upon this cause is doubted by Dr. Budd* who, states that he had, when visiting physician to the *Dreadnought*, continually to treat patients arriving from the coast of Africa in the most deplorable state from fever caught on the West Coast of Africa, but in none of whom did hepatic abscess exist. This fact, however, seems to me to indicate what has already been stated in regard to the varying liability of persons to the disease according to locality. Persons who have seen fever of whatever type on the African Coast and in India are aware of differences in their respective phenomena, while those of considerable Indian experience will, I think, agree with me in the belief that there suppuration of the liver is one of the many effects of malarial poisoning. Indeed, Dr. Budd, in the very next page after that to which reference has been made, alludes to such differences, and also to the possibility of the condition existing in India, although not elsewhere observed.

According to my observations, hepatitis occurs in greatest proportion among soldiers, next among officers. There is among women about one case of the disease per 100 persons for every four that occur among men ; and among children, although cases do occur, they are of great rarity. How far the habits of the three first classes affect their liability to this disease is a question that early attracts the attention of medical officers ; and notwithstanding that differences of opinion in regard to it do exist, I may briefly notice a few of the habits which distinguish them in the mass. The soldier, heedless of exposure to the weather, whether there be fierce sunshine, rain, or wind, seeks in "drink" temporary relief from the effects of his recklessness. The balance of circulation is thus upset, and the liver suffers. Officers, as a rule, drink less spirits but considerably more beer than soldiers ; they are not, as a class, so reckless as the men in regard to exposure and other irregularities ; and women are not only far more temperate, but expose themselves in an infinitesimal degree to the elements or to other causes of exhaustion.

It is doubtless more than probable that the great majority of cases of hepatitis in both soldiers and officers owe their cause to the circumstances just noted. It is by no means the case, however, either that exposure and indulgence will necessarily induce the disease, or that none except the drunken and the indiscreet become affected with the disease. Spirits may, and probably do, induce the adhesive form of inflammation or cirrhosis, but not the suppurative form, such as we are now considering. This has been observed to occur in England* as well as in India ; but as the affection chiefly concerns the army medical officer as being a secondary condition found in old soldiers whose service is nearly expired, and who probably would have been discharged had they survived, I need not further allude to it.

In former days, many cases of hepatitis doubtless were produced by the system then in force of allowing soldiers to drink undiluted spirits at the regimental canteen before their dinner, which meal is usually served up at one o'clock. Not only this disease, but others, more especially heat-apoplexy, were attributed to this cause ; and the circumstance led to the objectionable practice being abandoned. No doubt many cases of the disease are still directly induced by excesses at the present date, but I would protest against the theory often so plausibly adduced by authors "who live at home at ease," that the malady, and in fact, all others by which mortality in India is increased to a ratio so far beyond that of Britain, is always attributable to excesses and indiscretions on the part of the sufferers, and not to the climatorial influences of that country. There doubtless are instances as there are in England and elsewhere of individuals by their own indiscretion bringing disease and death upon themselves ; and there may even be a somewhat larger proportion who do so in India than at home. To assert, however, dogmatically, as is sometimes done, that such is the general condition of matters in India is not only in itself erroneous but cruelly unjust to our countrymen, who are defending our national interests in that country.

As we have already seen, children are not altogether exempt from the disease ; the circumstance, moreover, has often been noted that the lower animals brought to Bengal from the neighbouring hills and from Europe, manifest an equal liability to the affection as the human species. Dr. Hooker mentions this with reference to the yâk from Thibet, and there are few officers who have been accustomed to have home-bred dogs there that have not had to treat them for as grievous attacks of "liver" as they may have experienced in their own persons. These are notorious facts in India ; but I mention them here in the hope of being instrumental in removing opinions of an opposite tendency that exist among the inexperienced.

In my remarks on dysentery, I alluded to the value that would accrue, not only to individuals, but to the service, had we the power to state with tolerable precision, whether a particular person was, from his temperament and other characteristics, likely to be attacked by endemic tropical disease, than another of different conditions. This has a peculiar application to Hepatitis, which is believed to prevail in India to an extent equal in proportion to that of pulmonary consumption in Britain. Persons of bilious temperament are usually believed to be most liable to this disease ; but I have reason to doubt the conclusion, and would commend the inquiry to the attention of those who alone can furnish statistics by which it may ultimately be determined. Sir George Ballingale, when serving in the Madras Presidency many years ago, instituted statistics of this nature, but unfortunately they do not appear to have been kept up.

The tendency of inflammation of substance of the liver to run on to suppuration, and the rapidity with which in many cases it does so are both well known to many surgeons in India. They also know that it is not always in cases were the sufferer complains of the greatest pain that this unfortunate occurrence is really most to be dreaded, but that it is so in those where dull, heavy pain deeply seated is experienced, and where pyrexia and other constitutional symptoms are of inconsiderable severity ; and this is especially the case in persons whose residence in the country has extended over a few years. Other cases occur in which suppuration takes place absolutely without the presence of any symptoms, such as might be supposed to indicate the mischief in progress. An example of this will be seen presently in the case of Featherstone; many similar will doubtless present themselves to medical officers with regiments in India, amply confirming the observations on the subject by Andral, Abercrombie, and other writers on hepatic disease. Nor is it necessary that this condition be accompanied by dysentery. It may occur in the absence altogether of that complication. When suppuration occurs in the form of one large abscess, the patient seldom survives any considerable length of time unless, as in some rare instances, the contents of the abscess are evacuated by artificial opening, or discharge themselves by the lungs, or intestines. Even in such cases danger is great that death may occur while the process of evacuation is going on; either by exhaustion; by blood poisoning; by peritonitis or suffocation; yet, rare as recoveries are from such conditions they are sufficiently frequent to justify a hope that, under certain circumstances, this happy result may happen. Perhaps, indeed, recovery in cases such as these, rare, although it be in India, occurs in that country more frequently than it does in other tropical stations; at all events, there is scarcely a hot season in which some case of internal evacuation of a hepatic abscess, terminating in recovery of the patient does not present itself, and every now and then, also one in which a similar result followed the operation of paraceutisis. I had an opportunity, on various occasions while superintending invaliding at Calcutta, from 1862 to 1867, to observe such instances, and yet Dr. Davy * whose experience in the colonies was very extensive, states that he has never known recovery take place from an abscess of the liver, that either broke internally or was opened by the surgeon.

---

* On the Liver, page 95.

* Budd "On the Liver," page 98.]

One attack of the disease is very often, but by no means invariably followed by another, if the person attacked remains continuously in India, or returns to the country after short absence. As a rule, however, soldiers who are invalided to England on account of "liver" are not again efficient if sent back to that country; the exceptions alluded to being chiefly among officers and other members of the better classes, whose education and circumstances enable them to avoid or mitigate the causes to which a former attack may have been attributable. In many of the persons who thus, on their return to India, become again the subjects of hepatitis, they begin early in the hot season to experience indisposition; the symptoms, however, may not be of a nature to indicate the extent of visceral disorganization that is actually in progress, although the medical officer does not fail to observe the change in colour and expression of countenance that gradually take place, the so-called "dyspepsia" of which the patient complains, and finally the hectic flush and diarrhœa that form the alarming indications of the mischief that has been done.

Chronic hepatitis on the other hand, prevails to a great extent during the cold season; attacks of this form of the disease are also observed to be induced by sudden or great alternations of temperature, by the jolting incidental to long journeys, and by the fact of removal to the climate of the Hills. One indication obtained from these facts to which I may now allude, is the propriety of sending all invalids suffering from the affection by long sea journey to England instead of *via* Overland. Change to the Hills has not been shown by experience to benefit, as a rule, persons suffering from this affection, and indeed there is reason to believe that attacks are not seldom induced by it.

Many cases of deranged function of the viscus itself, and many of so-called dyspepsia or indigestion in persons who have spent a number of years in India date their commencement from an attack of hepatitis; others are but manifestations of chronic hyperæmia of the viscus, ending it may be, sooner or later, in suppuration. It is, therefore, unadvisable to retain in India a soldier or officer who manifests either of the above "functional derangements." Their true nature often reveals itself in an attack of dysentery or diarrhœa; and, after death, a succession of small abscesses deep in the liver are discovered. Similar symptoms in other cases are probably the result of induration of the organ, to which allusion has already been made, while cases are by no means rare in which functional disorder confined to the duodenum simulate liver disease so exactly, that correct diagnosis is by no means easy.

Cases are not rare among soldiers and officers in India where the secretion of bile is increased, giving rise to vomiting and to discharge of that liquid by the bowels. Attacks of this nature may, or may not, be attended by symptoms of inflammation, or congestion of the liver; they are generally acompanied by considerable constitutional disturbance; are present among new arrivals, but also occur among those who have been some time in the country. In the latter, such an attack often accompanies malarious fever, and should be held as indicating liability to actual hepatic disease, and the necessity of removal of the person suffering to a temperate climate. Cases also occur in which the passage of one or more gall-stones produces symptoms so similar to those of actual hepatic inflammation as to be distinguished from it with difficulty, if at all. Army surgeons can afford to relate their difficulties, as well as their successes.

I would in this place give an account of two cases in which openings were made into an abscess of the liver. In both the results was unfortunate, yet not under such circumstances as to discourage a medical officer, even had other cases of success, after a similar operation, not been on record. Puncturing, or otherwise opening an abscess in this organ, however, is a very different matter from the system of one time in use of *exploring* the viscus, a system that fortunately for the good of the sick soldier, has been all but abandoned in India. Prior to 1841, it was carried to excess for a short time, and when, during the three years succeeding, I served in that country in the *Buffs*, I had several opportunities of observing marks of the exploring needle in livers that presented no other morbid appearance.

With regard to the operation of opening abscesses of the viscus, Waring gives statistics according to which it would appear that, in 81 cases of hepatic abscess opened in India, there were 15 survivors, and 66 deaths; but I must refer the reader who desires complete details on the subject to French's Clinical Treatise.

(To be continued.)

◆

OVERCROWDING AND POVERTY CONSIDERED AS THE MAIN CAUSES OF DISEASE AND EARLY MORTALITY.

By Charles R. Drysdale, M.D., M.R.C.P.L., F.R.C.S.E.,
Physician to the North London Consumption Hospital.

It is one of the peculiarities of the class of sciences to which medicine and social science belong, that any phenomenon, such as disease and mortality, has so many antecedents that it seems perfectly impossible to some minds to construct any science at all in these questions. Hence the widespread scepticism as to there being any such science as the social science, and the same remark has often been made with regard to the medical sciences—for example, by Voltaire—that they are only conjectural, and want the element of certainty to be found in the more perfect sciences. There is a certain amount of truth in all this criticism, mingled with a great deal of error. Indeed, if we but remember that in the days of Pericles the study of natural science was so little advanced, that the illustrious Socrates considered that the study of the motions of the stars and other heavenly bodies was quite out of the province of the human intellect, we may become convinced, perhaps, that there have been some causes which have for ages retarded the progress of knowledge of the above-named branches of human science, in comparison with those of astronomy, chemistry, and physics. These causes it is not difficult to ascertain. They reside in the dogmatism which mankind has such a tendency to allow to reign over them in all questions of deep importance, and to the superstitions which have never been absent from the mind of man; *à priori* speculations, which fill the intellect full of unscientific ideas, so as to leave no place for attending to the suggestions of experience or scientific research.

---

* **Diseases of the Skin, page 156.**

There are signs, however, that the reign of superstition and false philosophy is fast coming to a close. For example, there cannot be a doubt that, since the decease of the distinguished Edinburgh professor, Sir Wm. Hamilton, the tendency of the best thinkers has been to adopt the views of Locke, instead of those of Descartes, and to admit into the study of the science of mind the same methods which are employed in the investigation of all other sciences, *i.e.*, to refer all knowledge to experience. And thus the illustrious names of J. S. Mill, Alexander Bain, and Herbert Spencer, all of them entirely of the scientific school, are fast becoming the guiding stars of all the best intellects in the kingdom. The positive philosopy, too, of Auguste Comte, although disfigured by many absurdities, and especially absurd in that portion of it which treats of society, has done incalculable service in removing at once, by what has been well called by Professor Bain the "drastic purge," many of the *à priori* opinions which have retarded the progress of the race towards happiness.

When we look at the phenomenon of such widespread poverty as we are at present afflicted with in this country, where there are said at present to be no less than two millions of persons under poor-law relief, there seem to be so many ways of accounting for this extraordinary occurrence in such an industrious and wealthy state, that the majority of persons are utterly unable to propose any remedy for the evil. This, as remarked by Mr. Mill, arises from the fact that the method of the social science is chiefly *deductive*, not, as in chemistry, *experimental*. *The deduction* which explains the overcrowding, the misery of our poor, the early death of themselves, and, above all, of their unfortunate offspring, is to be formed by considering how rapidly the human race, in common with all other animals, can double itself when abundantly supplied with food. Thus, it has been thought by Chalmers and others, that we have an innate faculty of doubling our numbers in not more than fifteen years, if amply supplied with the necessaries of existence.

It has been pointed out by Professor Malthus, in his admirable essay on population in the "Encyclopædia Britannica," that in the United States of America, from the year 1790 to 1810, the population nearly doubled itself, due allowance being made for immigrants, by the mere fecundity of the inhabitants of the states; and the analogy from the lower animals is so striking, when we consider the great rapidity of increase of sheep or cattle when abundantly supplied with food, that it is the more remarkable that this plain truth was not more clearly seen ages ago. Of course men are but animals, in that they require food to eat, and hence, like animals, they evidently may be expected, as they do, to tend to increase faster than they can get food in long-peopled countries such as the European states.

This *deduction* will be found, just as Newton's law of universal gravitation accounted for the paths of the planets, to account for the majority of the evils of civilised society, such as the overcrowding and incessant labour of the working classes, who are in many instances, as all physicians know, habitually living on an amount of food which is insufficient for health and strength. It also accounts fully for the overcrowding and deaths of the children of the poor or overcrowded classes. In short, just as Newton's law or Dalton's law was a short-cut to an explanation of the chief points in astronomy and in chemistry, so the Malthusian law of population throws a brilliant light upon the causes of the misery and disease which so much more frequently affect the poorer than the richer classes.

It is not expected by the writer of this short paper that anything he can say in such a small space as he dares to occupy, will convince his respected brethren of the healing art of the all-importance of the recognition of this "Law of Population," in order to understand the frequency of fever, consumption, infantile mortality, and other diseases among the poorer classes of our fellow-citizens. A prolonged study of the works of Malthus, Chalmers, Whately, Darwin, James and J. S. Mill, Bain, Garnier, Huxley, and other distinguished men will, he believes, end in convincing all that this law is as clearly proved as that of Newton's, by experience. Indeed, of all men, medical men ought most to attend to the question of the science of wealth, since without it the problems of state medicine are insoluble.

What, in the future, is to be the destiny of the race it is not in the writer's power to prophesy; but of one thing he feels convinced, that it is not possible that hygiene can ever be correctly studied apart from political economy, and that he who writes about the causation of consumption or fevers without taking into account the law of population, is in a grievous error. The distinguished physician, Villermé, of Paris, fell into no such mistake. He was well aware of the tendency of population to increase more rapidly than the means of subsistence, and he showed how much the mortality of different classes was influenced by comparative easy circumstances. And so with Professor Traill, of Edinburgh, and George Combe, the philanthropic phrenologist. All statistics show this.

That several able and distinguished members of our noble profession should be ignorant of the fact that this law is now held as an axiom in the science of political economy is deplorable. That they should speak unkindly of those who, knowing its truth, and animated by a desire to apply that great truth to assuage the incessant misery which they daily see before them, is distressing. What do such gentlemen understand by morality? Are they so far behind the positivism of this time as not to know that the only true test of morality is happiness? It is to be hoped that such intolerant addresses as those recently appearing in the pages of the MEDICAL PRESS AND CIRCULAR may soon cease to emanate from any member of a scientific profession; but that, calmly and in full possession of the facts, we may soon proceed to consider in what way we can prevent the miseries of over-population and starvation, whether by the prudent and common-sense practices of the French people—and we believe that is the best plan—or by emigration schemes, or how it may best be done. There is no foe to the human race so great, in the writer's opinion, as he who, by declamation, forbids open discussion on such all-important questions as that of "poverty and its relation to large families."

◆

ON THE TOPOGRAPHICAL FEATURES OF MAURITIUS, IN RELATION TO THE EPIDEMIC OF MALARIAL FEVER OF 1867.*

By WILMOT H. T. POWER,
Assistant-Surgeon, 2nd Battalion, 13th Light Infantry.

THE Island of Mauritius is of volcanic origin, having a lofty central plateau, surrounded by an incomplete rampart of hills, with various secondary hills derived from them. The land runs by slopes, more or less steep, towards the shore, a belt of flat land of varying breadth continuing the slopes to the sea shore. Towards the northern extremity of the island, a sort of irregular plain is formed, made up of alternate ridges and small valleys, the whole bristling with detached basalt rocks.

---

* Read before the Army Medico-Chirurgical Society of Portsmouth.

The *rivers* are far more numerous and with larger volume of water on the windward or eastern side of the island.

The soils consist of a stiff tenacious clay (more or less red according to the amount of contained iron), derived from the wear and tear of the basalt and allied rocks; and along the coast a varying belt of coral sand, which attains some breadth in certain parts of the island. A coral reef surrounds about two-thirds of the island.

Meteorology.—For some eight or nine months of the year the cool south-east trade wind prevails, and during the remaining months *local breezes which vary in direction in different parts* of the island. Thunder storms are rare, but during the hot and rainy season a certain amount of lightning occurs. There are two seasons—a hot and rainy, and a cool and dry season.

The marked characteristic of the hot season of 1866-67 was a want of. rain, and this was particularly the case in the three months September, October, and November, 1866, when, instead of the usual rain-fall, viz., 3·5 inches, only 0·7 inches fell.

In looking for the causation of the epidemic, we must remember that, for the last twenty years, the soil of most parts of the island has become more and more *dry*, owing to the cutting down of the forests, the trees of which act in two ways in regard to the amount of moisture deposited on the earth, viz.:—(1) By the extent of the surface exposed to mists and clouds by their leaves, they arrest much moisture from the air; and (2) by their shade they prevent the rain-fall from evaporating rapidly under the influence of the hot sun. Thus we have an unusually dry and hot season, acting on a soil which has become each year more dry, and has also been accumulating, for past years, an enormous amount of organic *débris*, brought down from the higher levels to the narrow band of flat land which runs round the island at the foot of the mountain slopes. This soil, moreover, is of small depth, is very impervious to moisture, and rests on an impermeable bed of basalt—a rock which parts very slowly with the heat it acquires from the sand.

The fever raged round about three-fourths of the island, forming in most places a narrow belt of fever-stricken land. The parts which escaped the fever are distinguished especially by a far *greater rain-fall always*, and by a somewhat lower temperature.

Thus we unavoidably come to the conclusion, that want of rain, and consequent dryness of the soil, at that season when the sun has most power, was at all events the marked and universal phenomenon which occurred in the fever districts. To my mind, the *drought was the existing cause* of the fever, and the island had hitherto escaped it simply because of the amount of rain-fall and great saturation of the soil in the hot months of the year. No malariæ was developed in those places where the soil was composed of clean, loose coral sand.

◆

ON POLYPI OF THE RECTUM.

By **Abraham Kidd**, M.D., L.C.P.I.,

Physician to Ballymena Fever Hospital.

Judging from the article contained in the Medical Press and Circular of the 17th March, from the pen of Mr. Holmes Coote, the eminent Surgeon of St. Bartholomew's Hospital, I am led to believe there is a great diversity of opinion among the profession, regarding the frequency of polypi of the rectum. Mr. Holmes Coote states, that he has been informed by a surgeon, now in practice, that the disease "is so common that cases came almost weekly before his notice," while the "late Sir W. Lawrence, assured him that he had never seen such a case!" It is well known that the latter gentleman had about the largest practice in London (both hospital and private) for probably over half a century, and if the disease had not been rare, I believe he would have occasionally met with it. From my own experience, I consider the illness is one that a surgeon very seldom sees; as I have been enjoying a practice more than twenty years, which I think, has been as extensive as what falls to the lot of most provincial medical practitioners, and I have only once had an opportunity of witnessing the malady. I have not seen it in any of the hospitals of the large towns. The case that I saw was that of a child, aged six and a half years, the son of a respectable shop keeper, in Ballymena, upon whom I operated a little more than a year since. The parents informed me that the patient had been labouring under the disease for two years previous to the time I was consulted, and that they had mistaken it for prolapsus ani, a disease not uncommon in childhood. Before my opinion had been asked, another medical gentleman saw the case, who, I understand, at once arrived at a correct diagnosis. At the commencement of the disease, it does not appear that the child suffered much inconvenience from the presence of the polypus, indeed, I believe he was rather amused at "the little thing," as he called it, coming down after each evacuation from the bowels. When the disease had lasted for some time, a considerable amount of uneasiness about the lower part of the rectum was complained of, and bloody mucus frequently was seen on the parts about the anus, but it could not be said there had been any hæmorrhage. After such defæcation, and the effect of pressing, a portion of the tumour was forced external to the sphincter. On introducing my index finger into the bowel, I distinctly felt the polypus and its attachment by a pedicle to the mucus membrane of the intestine on its anterior wall. The tumour felt about an inch long, and its circumference nearly as large as a person's little finger. With a common polypus forceps, used for operations in the nose, I took hold of the morbid growth, and after making sufficient traction, I gave the instrument into the hands of the child's father, which he fimly held, while I tied a ligature round the root of the tumour. I then cut off closely the ends of the ligature, replaced the polypus inside the sphincter (into the rectum), and the operation has been followed by perfect success; as the child has enjoyed excellent health since, and there is no appearance whatever of the disease returning.

When speaking of the affections of this region, I may briefly allude to a curious case that came under my notice a few years ago. A patient consulted me for what he considered was hæmorrhoids, which he stated, had come on suddenly, and was attended with severe lancinating pain. On examination, I did not find any appearance of the disease that he suspected present, but when I introduced my finger into the rectum, I felt a rough, irregular, foreign body impacted in the intestinal tube. This I had much difficulty in extricating, owing to its angular surface, and the spasmodic contraction of the sphincter. When I got it removed, I found it to be a small bone, about the size of an almond, and almost as irregular on its surface as one of the vertebræ. The patient informed me that a few days previously, he had been taking soup, and at the same time he was doing so, he was conscious of having swallowed by accident, the small bone that caused him so much suffering. I need hardly say that from the moment it was removed he was immediately and permanently relieved of his distress. I quite agree with Mr. Holmes Coote that, examinations "cannot be too minute and careful;" as this case will show.

ON CUTANEOUS ANGIONEUROSES.

By **Albert Eulenberg, Privatdocent in Berlin.**

Translated by W. D. Moore, M.D., Dub. et Cantab., M.R.I.A., L.K.Q.C.P.I.

In an abstract of the above paper, given by Dr. Thilesen, in the "*Norsk Magazin for Lægevidenskaben,*" Christiania, xxii Bind, 5 Hefte, the following *resumé* of the author's remarks, with reference to the essence and pathogenesis of Herpes Zoster is given at page 330.

1.—Zoster is a vaso-motor neurosis in the superficial cutaneous layers, an "*exanthematous angioneurosis.*"

2.—The vessels (the arteries, in severe cases also the veins) in the affected portion of the skin are during the eruption in a state of dilatation, relaxation; their tonic innervation is diminished, or for the time interrupted.

3.—The spinal ganglia are not, as Bärensprung assumes, the sole starting point of the affection, as no vaso-motor nerves take their origin from them, or are even contained in them, as moreover, zoster by no means occupies the whole seat of distribution of a spinal nerve, but follows at one time the anterior, at another, the posterior branches, at another only some of them, or even the extreme ramifications of the latter.

4.—Zoster has rather, so far as the trunk and extremities are concerned, its starting point in the vaso-motor nerve fibres, which partly pass from the sympathetic to the spinal nerves of the far side of the vertebral column, partly perhaps emerge directly from the spinal cord with the posterior and anterior roots.

5.—Zoster facialis originates in the vasomotor nerve fibres, which accompany the facialis and trigeminus, and with respect to the first proceed perhaps from the vagus, with respect to the latter from the sympathetic.

6.—Zoster presents in many cases, especially in the face, the form of a purely primary vaso-motor neurosis. In the cases where disturbances of sensibility attend zoster either as premonitory or concomitant phenomena, the possibility of a reflex origin cannot be excluded. The centre for reflex action is then the ganglia of the sympathetic. In these cases we have to do either with a *reflex irritation* with consecutive relaxation by peripherally increased irritation of the sensory nerves, or with a *reflex paralysis* in consequence of peripherally lowered irritability.

7.—The herpes occurring in acute febrile diseases, especially in the face, probably owes its origin to the action of the fever-exciting cause on the vaso-motor nerve system itself, since as the result of the primary tetanic contraction of the small peripheral arteries, a persistent paralytic dilatation of the same occurs.

Hospital Reports.

METROPOLITAN FREE HOSPITAL AND FARRINGDON DISPENSARY.

FURTHER CASES OF SYPHILIS TREATED WITHOUT MERCURY.

By Charles R. Drysdale, M.D., M.R.C.P., F.R.C.S.,

AND

Robert W. Dunn, Esq., M.R.C.S.,

A part of which was read at the Harveian Society on March 18, 1869.

(Continued from page 354.)

Case 34.—Edward W., aged three months, seen by Dr. Drysdale on the 12th of June, 1865, with eruption on buttocks and snuffles. The mother did not in this case appear to be infected, although the history was carefully inquired into. The eruption in this case was slight, and the prognosis favourable. The child recovered in six weeks under doses of chlorate of potash, gr. ij., t. d.

Case 35.—Patrick Dunn, aged two years, was seen by Dr. Drysdale on June 24th, 1865, with puckering and cracks at commisures of lips; teeth like pegs and notched at the tips. The mother again in this case seemed not to have been infected. She had another child, which died at seven months old. The little patient had suffered from rash at three months, for which it was not treated. Treated by Dr. Drysdale for a month with cod-liver oil and vinum ferri. The child was much benefited.

Case 36.—William Johnson, aged three years, came to Dr. Drysdale on the 16th of October, 1865, and died on November 14th. This child had jagged and rotten teeth; mucous tubercles at anus. The child had formerly been treated by Mr. William Allingham by chlorate of potash, and recovered its health entirely for upwards of one and a half years. The mother was infected in this case. The father was ill six years before the date above mentioned.

Case 37.—Dominick De Marco, seen by Dr. Drysdale on the 29th of March, 1865, with a very severe syphilitic eruption of a pustulo crustaceous order over face, body, and buttocks; the breathing very much affected by crusts in the nostrils. In this case the mother had not any symptoms or history of syphilis. The husband was a musician, and was in Paris. The child was treated with chlorate of potash, but died in a week after being seen. This was a very malignant case.

Case 38.—George Hodge, aged four weeks, seen by Dr. Drysdale on June 4, 1866, with dry syphilitic eruption on buttocks, which the mother said appeared three days after birth. The mother did not seem to have been infected, but her first child died at the age of fifteen months, her second at seven months, and her third was still-born. This patient recovered under doses of chlorate of potash, gr. ij., t. d.

Case 39.—N. W., aged two months. The mother of this child had primary chancre one year before marriage, and was treated at University College Hospital by mercury. Had suffered from syphilis more or less ever since. First child died one hour after birth with eruptions on hands and feet. The disease showed itself first when the child was six weeks old, by a syphilitic eruption over body and face and buttocks, with snuffles. The child did not take the breast well.

Seen by Mr. Dunn, July 21st, 1864. ℞ pot. chlor. gij. t.d. August 25th, better. September 20th, discharged cured. October repete. November 3rd, discharged cured. November 10th, an attack of measles; no relapse. January 3rd, 1865, died of hydrocephalus.

Case 40.—M. E. W., aged eight weeks. The disease first appeared when the child was seven weeks old, with syphilitic eruption on buttocks and face, and with snuffles. child emaciated. March 4th. Seen by Mr. Dunn, who ordered pot. chlor. gij. t.d. March 14th. Snuffles better. March 21st. Attack of bronchitis. April 17th. Rash fading; still coughs. April 30th. Child quite well. May 4th. Convulsions, one fit after another; never regained its consciousness. Died on the 6th. The mother became pregnant again for the fourth time. During the whole of her pregnancy there were slight symptoms of syphilis, such as ulcers on the tongue and in the throat. Delivered June, 1867, of a girl, which showed no signs of the disease until the age of four months, when it had a syphilitic eruption on face and body, and snuffles. Came under treatment September 10th, 1867. The child was well nourished, and Mr. Dunn advised the mother to bring it up by hand. ℞ pot. chlor. gi. ij. t.d. October 4th, child quite well. December. Discharged cured. In January, 1865, a relapse was seen in disease of the tongue. On February, the child was discharged cured, and he remained well until the present time. The mother has been pregnant again, but miscarried at the seventh month.

Case 41.—L. B., aged four months. Mother a prostitute, who denied having suffered from syphilis; but admitted having had a rash on the skin and sore-throat. This is her first child. The child was emaciated, had ulcers on the arms, mucous tubercles on the lips, and eruptions on buttocks, and snuffles. Seen by Mr. Dunn, June 14th,

1865. ℞ pot. chlor. gr. ij. t.d. August 4th. Discharged cured.

Case 42.—E. H., aged fourteen weeks, a nurse child, brought up by hand. When of the age of four weeks, the disease first showed itself. When first seen by Mr. Dunn, the child had syphilitic eruption on the face, buttocks, and ulcers at the arms ; the child was weak and fretful. September 1st, 1864, advised that the child be fed on milk, and that it be kept clean, and to take potassæ chloratis gr ij t.d. The ulcer was touched with nitrate of silver. Discharged cured on October 6th, 1864.

Case 43.—M. J., aged ten months. The mother was syphilitic, and had had six children, of whom four were still-born and two alive. The child previous to this died aged six months, with eruptions on the skin, snuffles, and emaciation. This child, the patient, has not been treated. It had syphilitic eruption on the face, head, legs, buttocks and hands, and mucous tubercles on the lips. It was emaciated, and the difficulty of breathing was considerable. Seen by Mr. Dunn August 24th, 1864. He ordered it pot. chlor. gr. ij. t.d., and half a teaspoonful of cod-liver oil, t.d. The child did well, and was discharged cured on November 31st.

Case 44.—G. D., aged sixteen weeks. The father was syphilitic, the mother not afflicted. In this, her first child, the disease first appeared at the age of ten weeks, and had continued ever since. On examination, Mr. D. found the child had syphilitic eruption on buttocks, and that it snuffled, was emaciated and had a wizened countenance. Seen by Mr. Dunn on January 26th, 1865. It was ordered pot. chlor. gr. ij t.d. March 26th, the child was well and discharged.

Case 45.—C. W., three weeks old, both parents syphilitic. The first child had a syphilitic eruption on buttocks, head, and face, and snuffled. Old, wizened appearance. Seen by Mr. Dunn on January 5th, 1865. He ordered it pot. chlor. gr. ij. t.d. On February 2nd, the child was without symptoms.

Case 46.—E. W., aged five weeks. Both parents syphilitic. A weak, puny child from birth. When three months old, a rash appeared on the skin, and the child snuffled. When seen by Mr. Dunn, March 8th, 1867, it had a copper coloured eruption on its buttocks and forehead, and snuffles, and the old man appearance common in such cases. ℞ pot. chlor. gr. ij. t.d. April 5th. Better. May 3rd. Quite well.

Case 47.—J. B., four months old. Both parents syphilitic. The disease first appeared when the child was three months old. Snuffles, emaciation. Mother has had three children before this, but all died of this disease. Child ordered by Mr. Dunn, on his first visit, May 4th, 1866, to take half a teaspoonful of cod-liver oil t.d. It was discharged cured on the 21st June.

Case 48.—S. B., aged three months. The father was syphilitic, but the mother had never shown any symptom of the disease. The child first had syphilitic symptoms when six weeks old. It had then rash over the body, face, and buttocks, snuffled, and was much emaciated. Seen by Mr. Dunn, May 1st, 1866. He prescribed gr. ij of chlorate of potash, t.d. On the 31st May, a half teaspoonful of oleum morrhuæ was added. On the 17th of June the child was fatter, and slept well, but still snuffled. The rash was nearly gone. On July 27th, the child was pronounced well.

Case 49.—C. S., aged six months. The father of the child admitted having had primary disease four years before marriage, which was treated with pills until the mouth became sore. He did not remember to have had any bubo, but had eruptions afterwards. The mother was quite healthy when seen. The disease first appeared on the child a week previous to being seen. The child had snuffled, and had a scaly eruption on the buttocks. On November 3, 1864, it was ordered to have gr. ij. of chlorate of potash, t. d. The symptoms were gone in a month. This case was under Mr. Dunn's care.

Case 50.—G. G., aged four months. Both parents syphilitic. Four living children born previous to this. All had died from eruptions on the skin, which appeared shortly after birth. These children were treated with grey powders and mercurial ointment. The mother had frequently miscarried. When Mr. Dunn examined the infant, he found it wizened and snuffling, with syphilitic eruption on the buttocks, legs, and arms. The child was treated by means of gr. ij. of chlorate of potash administered t. d., and was quite well in November, 1864. The date of the commencement of treatment is not noted.

Case 51.—M. O., aged five months. This child was quite well until vaccinated, when a syphilitic eruption was seen soon after the operation. When seen first by Mr. Dunn the child snuffled, had mucous tubercles on its lower lip, and syphilitic eruption on buttocks, face, and body. Both parents were syphilitic. The syphilis latent in the child, then, was brought out by the vaccination. November 10th, 1864, the child was to take gr. ij. of chlorate of potash t. d. December 10th, the child was pronounced well.

◆

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. Thornley Stoker, M.D., L.R.C.S.,
Demonstrator of Anatomy in the Royal Collge of Surgeons in Ireland.

COOMBE LYING-IN HOSPITAL.

Two Cases of Vesico-Vaginal Fistula treated successfully by Operation.

(Under the care of Dr. Kidd.)

Case 1.—Margaret McD., æt. twenty-six, was admitted into hospital, Feb. 21st, 1869, having been sent from Armagh by Dr. Robinson. She had been married fifteen months previous to her admission, and had given birth to one child, which was born dead in December, 1868, the labour lasting from Saturday until Wednesday, and being terminated by means of instruments, probably the forceps. Four days after delivery, her urine began to flow through the vagina.

When she presented herself, she was in other respects in good health. Examination revealed the existence of a fistula, sufficiently large to give passage to the thumb and four fingers, as far as their first joints, it was situated in the anterior wall of the vagina, lying rather to its left side and close to the os uteri ; from which it was separated by a very small amount of tissue, its margins were healthy, save at the lower part of the left side, where it was bounded by a band of cicatricial tissue, which tied it to the neighbouring pelvic bone. The examination of the fistula was rendered difficult by the prolapse through it of a great portion of the anterior wall of the bladder, which projected into the vagina, and displayed a vivid red surface.

On the 18th of March, the woman being chloroformed, was placed in the semi-prone position ; Spencer Wells' speculum was introduced, and Dr. Kidd proceeded to split the edges of the fistula in the manner recommended by the late Mr. Maurice Collis. At the left side, where the band of cicatrix existed, the formation of the flaps was found most troublesome, the operator, owing to the difficulty of displaying the parts, being guided in his work, principally by the sense of touch, and the slitting in this situation being effected by means of a curved scissors. The division of the edges being completed, eight hempen sutures were introduced by means of Liston's needle, and the edges of the fistula drawn together with a quilled suture, india rubber cord three-sixteenths of an inch in diameter, being used instead of quills, or pieces of catheter. The edges of the flap were then carefully brought together by points of iron wire suture, and lastly the vagina was plugged with carbolized sponge, and a catheter introduced into the bladder.

Twenty-two hours after operation, the quilled suture and the sponge were removed ; the wire sutures being allowed to remain for fourteen days. On removing the latter at the expiration of that period, a patch of granulations as large as a threepenny piece, which bled freely when touched, could be seen at the left side of the former seat of the fistula ; this was twice touched with the nitrate of silver, and gave no further trouble, healing readily before the twentieth day. A catheter being kept in the bladder until that period. There was no escape of urine through the wound after the operation ; it was necessary at no time to give opium ; and the bowels acted for the first time after an enema, which was given on the twelfth day.

The woman was dismissed from hospital, April 20th, being in excellent health, and menstruating for the first time since her labour.

(Under the care of Dr. Roe.)

Case 2.—Catherine K. æt. thirty-three years, the mother of five children, the last having been born June 3rd, 1868, was admitted into hospital, September 30th, 1868. Her last labour, during which she was attended by a nurse, had been a protracted one, the second stage having lasted at least eleven hours, and the funis, which had presented in the early part of the labour, having been, owing to the large size of the pelvis, readily reduced by the postural method by the medical man whom the nurse had the sense to send for when she saw the state of things.

Feeling quite convalescent, she got up on the 5th day, and two days afterwards, finding much pain in micturating, she consulted the nurse, who advised her that she had gravel, and recommended her to drink large quantities of gin ! The next day the urine began to flow per vaginam.

When examined, a *transverse* fistula was seen to exist in the anterior wall of the vagina a little above the neck of the bladder.

On October 5th, the patient having been placed under the influence of chloroform, Dr. Roe proceeded to operate, Banon's hook was passed into the opening, the edges were pared, and brought together *longitudinally* by seven points of iron wire suture.

She progressed favourably, getting occasional doses of opium and morphia, and having no movement of her bowels until she was given an enema on the 13th day. The sutures were removed on the 15th day, and the fistula found completely closed. She was discharged cured, Oct. 24th, 1868.

The foregoing cases present some features of interest. In Dr. Kidd's case the enormous size of the fistula, and the pressure of the prolapsed fundus of the bladder, rendered the probability of its complete closure by one operation very unlikely, and it affords a strong minute of evidence for adopting Mr. Collis's operation in cases of very large fistula. The use of the india rubber cord to complete the quilled suture, and the stuffing the vagina with carbolized sponge, are also points deserving of notice, the former in particular, because the pliable nature of the substance used, must render it much more adaptable, and more likely to close the opening completely than any other material. In Dr. Roe's case the successful closure of the transverse fistula in a longitudinal direction, is a method of procedure which should not be passed over, as it is one of those moot points, about which much difference of opinion exists.

◆

Hydrophobia in a Flock of Sheep.—During the past two or three months hydrophobia has been alarmingly prevalent in the neighbourhood of Preston, and especially so in the town itself. Many valuable dogs of all breeds have been destroyed at the police station with prussic acid, the whole number, good, bad, and indifferent, amounting to two or three scores or more. About three weeks ago, nine lambing ewes, the property of Mr. Draper, Bradley Hall Farm, Croston, six miles from Preston, were bitten by a strange dog, and having since exhibited undoubted symptoms of rabies, have just been all destroyed, The lambs were preserved.

Literature.

Transactions of the Pathological Society of London. Vol 19. 1868.

SECOND NOTICE.

In our first notice of this important work, we spoke of the diseases of the nervous system. We have now to speak of the contributions, to a knowledge of the pathology of the organs of respiration. Fifty pages are dedicated to this part of the economy. Dr. Charlton Bastian, brings forward a paper on a case of cirrhosis of the lung, with some of the results of an analysis of thirty cases of this disease. A man, aged thirty-three, had had a cough for years, and had been comparatively well until two days before admission. He died on the sixth day after admission into hospital. The man was thin, and the left side of the chest was flattened anteriorly, most notably in the infra-clavicular region, which was dull on percussion, whilst the percussion note on the right infra-clavicular space was natural. On the left front, mucous and coarse crepitation râles were heard. The sputum contained tenacious mucous. Pulse weak, 100, great dyspnœa and weakness. On the autopsy being made, it was found that the left lung was very adherent. The adhesions were due to the formation of a dense fibrous material, of almost cartilaginous consistence, growing outward from the thickened pleura, which in some parts was nearly one inch in thickness. Proceeding upwards, there were seen, on section, dense, white, ligamentous bands, consolidating almost the whole of the upper lobe of the lung, and intersecting its dark pigmented tissue in all directions, even when it was hollowed out in one or two places into smooth-walled cavities, about the size of a walnut, with semi-purulent contents ; these had the appearence of being produced by dilated bronchi. The lower lobe was also slightly indurated by an increase in the thickness of its fibrous septa, but not notably so. No tubercle, was found throughout this organ, either in the form of grey granulations of cheesy products. The right lung was also free from tubercle. This certainly seems a case similar to that which Dr. Clarke and others have separated from tuberculosis under the name of "fibroid phthisis." There appear, then, to be certain forms of lung diseases, characterised by a fibroid degeneration and induration of the lung-tissue, pure and simple, which have no necessary relationship either with pneumonia, or with tubercular phthisis.

Dr. Bastian thinks, that the evidence in our possession warrants us in believing that fibre-change, unassociated with either of the other two morbid products, may invade the lung and so induce another form of phthisis. In thirty cases given by the author of the paper, only five showed any trace of either chronic lobar pneumonia, or of tubercle in the lung.

Dr. Bastian adds another paper, giving specimens of lung, liver, and kidney, showing the close histological affinity of grey granulation, to the early stage of fibroid degeneration or substitution. The author looks upon grey granulation such as met with in acute tuberculosis, as the type of tubercle, because these alone have the same structure, in whatever part they may be situated. He however, shows, by his specimens, that it is difficult to distinguish the grey granulations, from fibroid degeneration under the microscope. Spherical, or ovoid nuclei $\frac{1}{4000}$th of an inch in diameter, are seen in both. In practice it is easy to distinguish these growths since tubercle is found in rounded masses, rarely exceeding a hempseed in size ; fibroid substitution proceeds continuously in different directions, often in the form of bands, and the proper tissue of the organ disappears before it. Tubercle has a strong tendency to undergo fatty degeneration ; whilst with fibroid substitution, the organ begins to diminish in bulk after a time, and there is no particular tendency to fatty degeneration ; tubercle is the anatomical lesion characteristic of a grave constitutional disorder ; fibroid substitution seems to depend more on local, than on constitutional, causes. Dr. Bastian will have it, that Laennec's "grey tubercular infiltration," Chomel's "chronic pneumonia," and Addison's "iron-grey induration," are all fibroid degenerations. The phthisis of grinders, too, is, he thinks, fibroid. Tubercles may, just as mechanical irritation does, produce a fibroid state of the lung tissue. Such facts, we agree with our author, should tend strongly to convince us not only that fibroid changes may exist alone in the lung, quite independently of any tubercular, or scrofulous taint ; but that when co-existing in the same organ, with the products peculiar to each of them, these changes may even be secondary and local rather than primary.

The next communication we shall advert to is one from Dr. Morell Mackenzie, on a case of cancerous ulceration of the epiglottis, with large cystic tumour of the neck in a man, aged sixty, who entered hospital for sore throat and difficulty of swallowing. No pain was felt on swallowing : but no solids could be partaken of but only beef-tea. The voice was very husky, and there was occasional cough with expectoration of tough slimy mucus ; dyspnœa occasionally. He dated his symptoms to four months back after a wetting ; large round swellings of glands of neck on both sides were seen. On *post-mortem* examination it was found, as had been seen by the laryngoscope, that the right half of the epiglottis was destroyed by ulceration, and a large semi-globular outgrowth encroaching from the left wall of the pharynx, which had been supposed to be a gland enlarged during life ; but which was a cystic tumour.

Dr. Douglas Powell brings forward a case of cancer of the lung and bronchial glands, liver, and pancreas, where the patient died at Brompton Hospital, under the care of Dr. Pollock. The woman was thirty-eight years of age, and her father and mother had died of phthisis (?) at the ages of forty and sixty. Her health was good until fifteen months before death, when she had hæmoptysis of black and clotted blood. She had bad cough, dyspnœa, emaciation, and absence of catamenia. There was absolute dulness of front of left lung, tubular breathing in supra-spinous fossa and scapular region, and deficient respiration, with dulness from scapula to base ; cardiac dulness extensive, with double murmur at base. *Post-mortem* examination revealed pericarditis, cancerous glands seated above the trachea, of a schirro-encephaloid character. The lung at the upper two-thirds was consolidated, of a mottled grey appearance, with numerous fine fibrous bands. There was slight thickening of the lung pleura, and at the apex a cavity in the pleura filled with puriform fluid. The liver, on section, was found to be finely pigmented, and the appearance was that of infiltrated cancer, with pigmentary deposit. The spleen normal. The kidneys somewhat granular and enlarged. The head of the pancreas, on section presented the appearance of schirro-encephaloid cancer.

In a case of perforation of the lung, or pneumo-thorax, shown by Dr. Douglas Powell, the clinical notes show that the right anterior and axillary bases were resonant : respiration was inaudible, but much creaking and friction sounds extended as high as the nipple of the right side, dyspnœa great. The patient died two days after perforation, no amphoric respiration, nor indeed any respiration was heard.

Dr. Morell Mackenzie relates a case of supposed cancerous ulceration of the larynx in a female patient, age thirty-six, of the London Hospital. The throat was perpetually dry and smarting. Deglutition exceedingly difficult and painful, so that she had to confine herself to farinaceous foods and fluids, the voice was suppressed and hoarse, there was frequent loose cough, with constant thick frothy expectoration. The laryngoscope showed a deep, irregular ulcer, of ashy-grey colour, on the left arytænoid cartilage. The patient died ; we think that in this case tracheotomy might perhaps have done good.

In another laryngeal case, cited by the same gentlemen, where some growths pressed on the left recurrent laryngeal causing paralysis of the muscles of the larynx, Mr. Couper performed tracheotomy : but without much benefit to the patient, who died.

Dr. Gibb narrates a case of removal of a tolerably large growth on the free border of the right vocal cord, by means of the wire-loop of his laryngeal *écraseur*. The tumour was of the size of a small bean. We cannot too highly admire the delicacy of manipulation required for this little operation.

In our next notice we shall refer to the section of disease of the organs of circulation, which occupies 106 pages of the *Transactions*.

◆

A Manual of the Diseases of the Skin. By Balmanno Squire, M.D., F.L.S. (Smaller Edition). London : Churchill and Sons, 1869.

The author's description of cutaneous affections in this work is given in a lucid manner, though of necessity with briefness ; and this causes us to regret that too often the equally valuable therapeutic information for which practitioners chiefly consult any publication on a special medical subject, should be so imperfectly supplied. The classification adopted by Willan, is assumed for the basis of arrangement with certain modifications. The author states, "for the great majority of cutaneous diseases, we are able to propose no better system of arrangement, than that of Willan ; because in truth our knowledge of them is not sufficiently superior to his to enable us to do so." There are four natural orders, which he classifies in separate groups. 1. The syphilides. 2. Sebaceous diseases of the skin. 3. Animal parasitic diseases. 4. Vegetable Parasitic diseases. Some woodcut illustrations of animal parasitic affections appear in the work. Many of them are copies of Robin and Bazin's drawings, and their seems no satisfactory reason why such stock illustrations as the "acarus follicularis," p. 132 ; and the "acarus scabici," p. 146, should not have also been copies from previous authors, instead of costing Dr. Squire the trouble of a microscopic drawing, or a micro photograph, for they reveal no difference whatever from the illustrations of the same animals published years ago.

We do not wish to cavil at the directions given for treatment unnecessarily ; but the author's own admission in his preface is, " that we have now better means at our command than a course of a series of sarsaparilla, or of dulcamara" again, our expectations are raised by reading, " I have found a rational, as opposed to an empirical, constitutional treatment, far the more successful ; and furthermore, my experience has gone far to prove that a careful selection of local remedies is at least as important an element in the cure of cutaneous diseases as even the best directed constitutional treatment." After promises like these we turned with high hopes of profit to the work itself ; let us quote the author's own directions for the cure of lupus.

" The internal remedies employed are cod-liver oil, the preparations of iron, more especially the iodide, iodide of potassium ; the liquor arsenicalis ; Donovan's solution ; the biniodide of mercury ; quinine ; the various bitter infusions, more particularly those of gentian, hops, or of the leaves of the walnut tree ; sea water, &c.

Externally, baths containing sulphuret of potassium, iodine, carbonate of soda, sea-salt, or sea-weed are made use of.

" The *local remedies*, are poultices and emollient applications to remove the crusts ; oil of cade ; a solution of tannin in glycerine ; the tincture of iodine either pure or mixed with an equal quantity of linimentum iodinii ; cashew nut oil ; ointments of iodine, of iodide of potassium, or of iodide of lead ; creasote ointment ; ointment of iodide of arsenic, or of either the green or red iodide of mercury ; chloride of zinc ; Vienna paste (equal parts of potash and lime) ; terchloride of gold ; arsenic ; sulphate of copper ; nitrate of silver in powder or solution ; butter of antimony; the actual cautery ; carbolic acid ; sesquichloride of iron ; and nitrate of mercury ; caustic potash ; chromic acid, &c."

This is at the best an index of escharotics ranging from mild to severe, and we believe little is to be learned from such lists as these. A practitioner would require to arrange for consultation with Dr. Squire, to ascertain which he recommends, or whether he has obtained any decided advantages from " a careful selection of *local remedies* " out of the entire catalogue. Nor when we turn back to the sum of internal treatment, presented to us do we see much difference between it and the details of practice in past generations. We are at a loss to know which of them Dr. Squire considers best fulfils his high aim of substituting, a rational, instead of an empirical, treatment.

We might have selected many other diseases instead of lupus for these remarks. So far as the descriptive portion of the work is concerned, we repeat it is very good ; but we are not so well satisfied with the directions for practice.

◆

Another Poisoning Case in Marsielles.—The *Phare de Marseille* has the following :—" We thought we had done with the poisoning woman. Unfortunately we have to report another crime of this kind. One of the accomplices in the crime which has spread terror in the arrondissement of Arles is the curé of one of the parishes in the jurisdiction of the Archbishop of Aix. The following facts have been reported to us :—A young woman named T——, the wife of a labouring man, was in the service of the Abbe D——. The husband, to the astonishment of everyone, died suddenly, and a suspicion arose that he was poisoned by the wife. She was accordingly arrested. It is said that she admitted the crime, and that she was urged to it by the Abbé E——. He was then also arrested, and is now confined in the prison of Tarascon. Both will take their trial at the next assizes of the Bouches-du-Rhône."

WEDNESDAY, MAY 5, 1869.

THE POOR-LAW MEDICAL MEETING.

SEVERAL topics, not only of importance to the Profession, but which also have a special bearing on the subject of Poor-law management were brought forward and discussed at the quarterly meeting of the Poor-law Medical Association this day week. Besides the inadequate remuneration of Poor-law medical officers, which has long been a subject of just complaint in the profession, and which the Board up to the present time show no disposition to regard with favour, the increase of pauperism was referred to, and it was stated that the evidence given before a Select Committee of the House of Commons which had never been disproved showed that 72 per cent. of pauperism depends on sickness. Statistics were presented by the chairman to show that "other things being equal"—we quote his words—"wherever there had been in a union or parish insufficient out-door medical relief, there, in the fifteen years ended in 1867, was a steady increase of expenditure on in-door maintenance." He referred to Birmingham, Brighton, Bethnal Green, St. Luke's, and other unions, all which led him to the same conclusion that neglected sickness among the working classes is one main cause of the increase of pauperism in this country, so much so, he said, that the character of workhouse inmates has almost entirely changed within the last few years, consisting now generally of sick, aged, and infirm.

The inadequacy and inequality of the remuneration of medical officers is without doubt closely connected with this subject. It was shown that in thirteen unions these officers now receive less than 1s. per case—in twelve between 1s. and 2s., and in fourteen others, more than 2s. and less than 3s., and in some instances out of this miserable pay they are expected to find the drugs. In such a state of things as this is it possible that the sick can be properly attended to? Is it not imposing a heavy and responsible task, and at the same time withholding the means of performing it? We own to a feeling of surprise sometimes that men should be found, men of talent in the profession who are willing to submit to such injustice, and such appointments where the value of their services is almost entirely ignored. Capability and devotedness in every other sphere are prized and rewarded, while the Poor-law Medical Officer, whose duties are the most arduous and self-denying, and intimately connected with the welfare of society in general, is often the most underpaid and neglected of all.

At the same meeting a resolution was proposed and carried, recommending the establishment of dispensaries in connexion with the parish system. Our opinion is decidedly in favour of the suggestion. It would no doubt relieve the medical officer of much hard labour, and faciliate the means of conveying out-door relief to the poor. Patients would know where and when to apply, and obtain advice and prescriptions more readily than is possible under the separate mode of action. It is only fair that every facility should be given to those who do the work, and every hindrance be taken out of their way. Then we shall have a right to demand that the work be properly done, and to blame him who, under conducive circumstances, neglects it. We are very sorry to say that now blame often falls upon those who are not only innocent of offence, but who are carefully and constantly pursuing their unrequited labours.

It was not before its time, nor before its efforts were sorely needed, that this association came into existence. No doubt it was a sense of the grievances they had to undergo which induced the leaders in this movement to take action at first, and the wide support they have met with shows that the evil against which they are struggling is both wide-spread and real. We congratulate them on the success they have already achieved, and the course they have marked out for themselves. The object cannot now be overlooked. Not only the profession, but those in authority—Parliament, the Poor-law Board, Parish Guardians begin to see that there is a crying evil which ought not to have been suffered so long, and which must be speedily remedied. We congratulate the association particularly on the notice it has received from a well-known member of the General Medical Council (Dr. Rumsey). No one is more capable of forming a true opinion on the subject, and no one more ready to advocate those measures which, while advantageous to the profession, will promote the general welfare of the community. We quote his recommendation to the association, to strive for the following objects:—

1. That the Irish system of Poor-law medical service shall be taken as the basis or model of any organic change in England:
2. That medicines and appliances shall be provided at the public expense, and dispensers appointed in places of sufficient population:
3. That the whole cost of such provision shall be borne by the local or union fund: and,
4. That the whole (not half) of the salaries of the medical officers shall be defrayed out of national funds.

HOSPITAL DINNERS AND TAVERN KEEPERS.

THIS is the season of Hospital Dinners, and those who cater for them must, we fancy, be driving a good trade. We do not often dine out, but are now and then tempted to assist at entertainments got up to promote charitable objects. In such cases an inferior dinner is a double annoyance, because it often diminishes the subscription lists we are anxious to increase. Last Friday we were present at the dinner on behalf of the North London Consumption Hospital, which was ably presided over by the Lord Mayor of London. His lordship pleaded the cause of the charity with earnest and simple eloquence, which we believe would have been more effectual if the directors of the Freemasons' Tavern Company had fully sustained their reputation. Some we are aware "had a capital dinner," and were properly waited on. The bill of fare offered plenty of choice, and the quality and cooking of most of the things we tasted were satisfactory. But there was a hitch somewhere. It is not our business to say who was to blame, but we record the facts as we found them, in the hope that other charitable dinners may reach nearer the mark of perfection. The writer of this took his seat at the right-hand table, with a friend on each side. Two of us have not seldom dined in hotels in England, and also on the continent, and know, we think, how a dinner should go off. We have admitted there was a good *menu*. The choice was ample on paper, but we complain that such choice did not exist in fact. Here is the *menu*, as put in our hands. We have printed in italics every dish that either of the three caught sight of, not tasted :—

NORTH LONDON CONSUMPTION HOSPITAL.

ANNIVERSARY FESTIVAL,
Friday, 30th April, 1869.
THE RIGHT HON. THE LORD MAYOR,
In the chair.

MENU.
Potage.
Puré d' Asperge. Printanier clair.
Fausse Tortue.

Poisson.
Souchet de Carrelets. Anguilles à la Colbert.
Saumon. *Turbot.* *Blanchaille.*

Entrees.
Cuisses de Volaille à la Caneton.
Kromeskys de foies gras à la Moderne.
Côtelettes de Mouton à la Madras.

Releves.
Chapons Braisés aux trùffes. Poulets rôtis aux cressons.
Poulets bouillis à la Printanier.
Vol au vent aux huitres. *Jambons.* Langues de Bœufs.
Quartiers d'Agneau. *Hanches et Selbes de Mouton.*
Pommes de terre nouvelles. Asperge.

Second Service.
Rots.
Ruffs and Reeves. *Canetons.* Poulets d'Afrique.

Entremets.
Gélées aux liqueurs Genoise au Chocolat.
Dames d'honneur. Compote d'Oranges. *Poudins glacés.*
Dessert.

It will thus be seen that three gentlemen never saw half the dishes, and, of course, neither of them had the chance of partaking of all the things they saw. All we know is that the articles printed in italics were produced at our table, and that we were able to get some of them.

Whether the waiters are to be blamed, or who, is not our affair.

We have known other charitable dinners at other hotels when some dearth existed, especially when the numbers were very large, and we have more than once intended to speak of it publicly, but have been restrained by various considerations. We can hold peace no longer. Here is a most excellent charity, doing an amount of good in an unostentatious way, that should give it a claim to every charitable person, running the risk of injury by mismanagement of the contractors for its anniversary dinner, and that when dinners by the dozen are being given for other charities. It is time to draw attention to the subject in the interest of the charities that may suffer by reticence. It is a common belief that a good dinner induces the partakers to be more easy as to the pocket. Whether this be so or not we do not care. It is the belief on which committees of charities act, and it is their concern to look into such things as these. In some cases defects are made up by the wine, but in this instance that course was not practicable. We consumed a bottle of light Hock between the three. Champagne and Moselle were offered, and we took a glass each. Sherry and Port were there at first. We do not affect these strong concoctions, and having poured out about a teaspoonful of each to taste, and not approving, would not drink them. We secured a glass of claret each, and then had the pleasure of gazing at the empty decanter the rest of the time, for it was not refilled. We actually complained to the waiter of the scanty supplies, told him we did not care for the Sherry, and asked for a little more of the light Hock. After some time he brought us an unexhausted bottle of Moselle, from which we drained a glass and a half between the three. After that we said no more, but, as the toast-master kept up the cry, "Gentlemen, please to charge your glasses," said we to each other, we should like the chance. It is not that either of us wanted strong wines, or very valuable ones. Our rejection of Port and Sherry proves that. We have been long enough in wine-growing countries to prefer something light. Could we have had the cheapest specimens of Denman's Greek or MacGregor's Hungarian wines, we should have been content, for they are quite strong enough, and being pure wines, we infinitely prefer them to the stuff that the British Philistine is supposed to most enjoy. We are inclined to blame the waiters for one reason—that it was difficult to get a second morsel of bread.

We sat it out, nevertheless, for Miss Spiller's songs were interposed, and furnished us with something more pleasant to remember than that tantalising empty decanter amidst the cry of "Charge your glasses."

"THE BRITISH MEDICAL JOURNAL."

WITH more interest and curiosity than the affairs of the British Medical Association have been wont to excite, the profession has received the balance-sheet just issued by its treasurer, Dr. Falconer. The interregnum between one year's celebration of the Association Medical pic nic and the next, is seldom marked by any greater sign of life than a semi-comatose demonstration of existence, and as far as any professional object is served, or any useful result achieved, the British Medical Association might as well be interested in the paper trade as in medicine.

When, however, it was learned that its council had caught the editorial *leprechaun*, actually bought up the life and soul of the opposition establishment, it was settled *nem. con.* that the revivication of the association was already an accomplished event, the acumen literary and trading, of the new editor was to lead the association at once from musty impecunious mediocrity to the omnipotence which public favour and a plentiful pocket confers. In the plenitude of its anticipations the council delivered over the unresisting association to its new editor to be bled and purged to any extreme, so as restoration to health was effected. The patient is now produced for inspection. He is corpulent truly and sufficiently long-winded, and his doctor displays with complacency the fatness of his body corporate; but alas! his appetite is more stupendous, his intellect more sleepy, and himself more expensive and relatively less useful than ever. To the ineffable distress of the association the new doctor has absolutely Bantingised their puny protegè.

No less a sum than £5,571 has passed through the fingers of the treasurer within the year. A marvellous growth of income and a right royal endowment worthy of noble objects and deserving of great results. What a subsidy for a Medical Benevolent Fund—what invaluable help to medical reform—what stimulus to scientific research—what welcome advocacy to medical interests might such a sum produce! Where is the medical orphan nurtured from the charity of the association? Where the profit to either the mind or body of the profession? What impression made upon the legislature in any of the ten thousand objects which the profession has at heart? An infinitisemal crumb of £52 has slipped from the all-absorbing maw of the *British Medical Journal;* and with the £5,000 have passed away all the aspirations of the profession as to what the association might have done.

It is no paradox to say that with all its achievements the *British Medical Journal* is an utter failure.

As a commercial speculation it is condemned out of its own mouth, for who will give thanks to a trader who, with almost unlimited money at command, and inestimable advantages on his side, closes his financial year with an enormous settled expenditure, and no dividend whatever; and this while others can show handsome profits present and future.

As a scientific exponent it is an utter failure; for with an absolute and rigidly assisted monopoly of the writings of its subscribers, it has done nothing which has not been much better done elsewhere, and its managers have sunk a fortune in paying for an inferior quality of that article which others get for nothing.

Lastly, it has utterly betrayed the objects of those who confided to the association their subscriptions. The cries of the profession for publicity for its views have been completely forgotten in a ridiculous and useless printer's speculation; and now, as in the fable, the oyster shell is complacently presented to the gaping suitor, while the fish itself, with all its luscious flavours, has gone to minister to the satisfaction of the attorney.

Two courses only seem to us to be open to the association. They must choose between printing and medical representation. If they elect to resolve themselves into a joint-stock printing company, they have certainly a right to expect at least £1,000 a year profit from their manager.

If they choose to retrace their steps and become once more a representative medical corporation, they must moderate the tragedy transports and envious competitiveness of their editor, make their own organ what its journal is to the Society of Arts, and put the contributions of their members to its legitimate purpose, the forwarding of medical interests.

◆

SCOTLAND.

GENERAL COUNCIL OF GLASGOW UNIVERSITY.

The twentieth meeting of the General Council of the University of Glasgow was held last Wednesday in the Common Hall of the College. The Very Rev. Principal Barclay in the chair, supported by the various Professors.

Report on Graduation.—The Council took up the report of the Committee on Graduation, which pointed out the fact that while professional bodies had vied with each other in the encouragement that they had given to students to proceed to graduation, there had been no steady or marked interest in the number of those who had sought for or obtained a degree. If this indifference, to or neglect of, graduation be not obviated, the General Council would soon be greatly diminished in numbers, and to a large extent consist of those who had become members of it in virtue of the degree which was necessary to enable them to follow with credit and success the profession they had adopted. To remedy this state of matters, the committee suggested that in order to obtain a mere Pass degree, the student who applied for it should be examined chiefly, if not solely, on the books read and the subjects treated of by the professors in their classes, both in literature and science, during the years of his attendance on these classes.

The Rev. Dr. Smith (Cathcart) moved that the report should be adopted, and transmitted as a recommendation to the University Court.

The Rev. Mr. Niven seconded the motion.

Professor **Ramsay** moved as an amendment to the motion of Dr. Smith, "That it be remitted to the committee to reconsider on a wider basis the subject of the report, and to bring up an amended report to the future meeting."

The Rev. Dr. Bryce (Belfast) seconded the amendment.

After some discussion, a show of hands was taken as between Dr. Smith's motion and Professor Ramsay's amendment, when the Principal declared the former to be carried by a large majority.

The New University Buildings.—Mr. James A. Campbell said—I have to report that the subscriptions towards the erection of the new University buildings have made considerable progress during the last six months, the amount received in that time being £5,951, making the total subscriptions at present £118,461. That sum has been subscribed by 711 contributors. I would just say, that as we are now within £2,000 of the sum which was lately stated as necessary in private subscriptions to entitle us to the whole amount of the Government grant, it is perhaps necessary to say that there is still room for the exercise of as much liberality as we can find from the friends of our University.

The Rev. Dr. Buchanan said he had been requested to move:—"That the General Council, having received with satisfaction the report of the continued progress of the subscriptions for the erection of the new University buildings, again commend the subscriptions to the active support of the members of Council, and reappoint the Subscription Committee—Mr. James A. Campbell, convener." The motion was agreed to.

The Scotch Education Bill.—Sheriff Galbraith afterwards introduced the motion on this subject of which he had given notice, as follows:—"That the Council, recognising the necessity of securing education to every child in the country, approve of the proposed measure, as in many respects calculated to have the effect of spreading education over a wider area than heretofore. Resolve—That in their opinion—1. In providing that education for the people, the existing schools should be respected, and their position carefully conserved; 2. That the proposed legislation should be mainly supplemental, providing for the supply and maintenance of schools in neglected places; 3. That the present revenues of the parish schools as such should not be abandoned—in any event that these sums should be deemed local contributions; 4. That no part of the existing school organisation should be disturbed wherever it is found to be efficient, although schools should be supplied when not found sufficient in cases in which voluntary effort has failed after being called upon; 5. That as regards the appropriation of any rate to be levied, their should be no distinction made among schools, whatever the religious profession of the trustees or managers may be, and that all schools meeting Privy Council requirements should participate in the rates; 6. That care should be taken that the 'use and wont' of religious teaching in Scotland be not endangered; and That the Council resolve to petition Parliament to give effect to these resolutions, or to such portions or modifications of them as the Council may adopt."

After a spirited debate, this motion was carried.

GLASGOW UNIVERSITY BUILDINGS.

The new buildings progress very rapidly. Nearly 1,100 men are employed upon them. A railway from the quarry, on the western extremity of the grounds, has been laid down, and blocks of stone of several tons weight are thus easily transported. Seven of the professors' houses have got one storey high, and four others are but little behind them. The class rooms of the eastern side are roofed in, and a great portion will be ready for the opening of the next winter session.

ABERDEEN UNIVERSITY.

The Chair of Midwifery has been conferred upon Dr. Inglis, who will enter upon his duties forthwith.

MONUMENT TO DR. ADAMS.

A wall tablet, in three panels, has been erected to the memory of Alexander Maxwell Adams, M.D., L.R.C.S.E., F.F.P. and S.G., Provost of the Royal Burgh, of Lanark, who died in office at Lanark, on the 17th day of July, 1867, in the fifty-fourth year of his age.

THE CONVERSAZIONE OF THE EDINBURGH UNIVERSITY.

In our last issue we were unable to do justice to the subject, the interest in which has even yet scarcely abated. It is too late now to describe the brilliant hall or its various compartments devoted to the different departments of science as indicated by inscriptions over the walls, reading along the two sides in the following order :—Northern Lights, Meteorology, Astronomy, Horology, Chemistry, Telegraphy, Literature, Natural Philosophy, Music, Curiosities in Food, Physic, and Poisoning ; Botany, Precious Metals, Natural History, and Physiology. It would, however, be too bad not to chronicle the fact that an enthusiast on the subject of cruelty to animals protested in a letter to the *Daily Scotsman*, against the experiments proposed by Dr. Hughes Bennett, and received in the columns of the same paper a caustic reply. The letter of the learned professor of physiology is really worth citing. It is as follows :—

> Sir,—In your paper of yesterday " A Valetudinarian " says of the conversazione to be given in the University to-morrow evening, and of the misery which he thinks will result from firing the time-gun—" I can only account for the representatives of the medical faculty becoming oblivious to such considerations by the fact that scientific experience ignores individual suffering." " At former University or College of Surgeons' conversaziones, I have seen—and shivered to see—a poor frog tied down under a microscope, that gaping dilettanti might observe upon its painfully extended legs the beautiful phenomena of the circulation of the blood." On a former occasion (see *Scotsman*, November 9th) I took an opportunity of dwelling, in your pages, on the ignorance of physiology among the public, and on the propriety of introducing into general education some study of the animal functions, and of the sanitary conditions necessary for their own health and peace of mind. The ideas of "A Valetudinarian" offer a good commentary on my remarks. He shivers at putting a frog to the inconvenience of separating its toes, in order that the transparent web between them may be examined with the miscroscope. He would probably eat with the greatest gusto a fresh oyster, unconscious that in crushing between his teeth the palpitating heart and other living tissues of that animal he communicates to his palate a peculiar relish. His imagination may be so vivid as to represent to himself that the oyster takes a pleasure in this procedure, whilst the equally cold-blooded frog cannot separate its toes without agonising torture. I shall not speculate further on the peculiar ideas of your correspondent, but state my intention of exhibing to the visitors of the University to-morrow evening the phenomena of the circulation in living animals on an unusually large scale. I beg to inform them that not the slightest suffering will be occasioned, as they will all be fast asleep. For the benefit of valetudinarians generally, I shall also show the ciliary movements on the gills of an oyster, convinced that the remarkable vital phenomena so demonstrated will in no way diminish the demand for this edible animal, or lessen the value of our marine fisheries.—I am, &c.
>
> J. Hughes Bennett, M.D.,
> Professor of Physiology.

UNIVERSITY EDUCATION.

The condition of the four Scotch Universities is at present exciting much interest, and the *Daily Scotsman* has collected returns, which, in default of any other, may be referred to, though that journal suggests that a parliamentary return would be more satisfactory. The following table shows the number of students in attendance in the past Session :—

	Faculty of Arts.	Medicine.	Law.	Divinity.	Total Students.
St. Andrews...	152	—	—	31	183
Glasgow	755	302	115	86	1,258
Aberdeen	321	166	5	30	522
Edinburgh ...	661	442	306	75	1,484
Total in Faculties...	1,889	910	426	222	3,447

The *Scotsman* adds that :—" A number attend more than one Faculty, but it cannot be stated with accuracy ; probably 200 should be deducted from the gross total, in order to arrive at the actual number of Scotchmen attending the Scottish Universities. Now, if the population of Scotland at this moment be, in round numbers, 3,200,000, it will follow that one in 1,000 of our countrymen is presently in attendance at a University (the number of Scotchmen attending English Universities being quite inconsiderable.)

Taking a period nine years back—session 1859-60—we have the following general results as to attendance in the Scottish Universities in the several Faculties :—

	Arts.	Medicine.	Law.	Divinity.	Total.
St. Andrews...	109	—	—	30	220
Glasgow	625	317	89	88	1,119
Aberdeen......	418	130	17	90	645
Edinburgh ...	658	554	243	95	1,550
	1,810	1,001	349	303	3,544

It is fair to deduct for " partial " students in Divinity say 44, leaving as the gross total 3500 ; so that the whole attendance at the Universities nine years ago was apparently fully greater than now, although the population was say 150,000 less than at present. In fairness, however, it is the increase of certain classes of the population alone that ought to be taken into account—those above what are called the working classes. At the same time, it is gratifying to observe that in the fundamental Faculty—namely, Arts—the attendance has considerably increased."

EDINBURGH.

A Conversazione in the hall of the Royal College of Physicians, Edinburgh, was held on the 30th ult., when Dr. James Hutchison Stirling delivered a lecture on " Dr. Huxley's Inferences from Protoplasm." A large company attended on the invitation of the President and Council of the College, and among those present were the Right Hon. the Earl of Southesk, Principal Sir Alexander Grant, Sir James Coxe, Sir Y. Simpson, Bailies Cousin and Fyfe, Councillors Colston and Muirhead, Professors Douglas Maclagan, Tait, Masson, Muirhead, Balfour, Professors Macgregor and Duns of the Free Church College, Professor Harper, Sheriffs Gifford and Hamilton, Rev. Drs. Grant, Wallace, William Smith, Thomas Smith, Davidson, and Peddie, Rev. Messrs. Mitchell, Leith; Brown, Gardner, Thorborn, Leith; J. Tomson Kelman, A. Moody Stuart, Mackenzie, Main, Fraser, St. Bernard's; Cumming Newington; Messrs. Campbell Smith and Alexander Nicolson, advocates; Mr. T. J. Boyd, Master of the Merchant Company; Dr. Donaldson and Mr. Carmichael, of the High School; and a large number of the members of the medical and legal professions. Dr. Moir, the President of the College, received the company at the entrance to the hall; and thereafter introduced the lecturer to the meeting. He expressed the pleasure which it gave to the Council to have the first lecture given in their new hall delivered by a member of the medical profession, who was also one of the ablest metaphysicians of the day. (Applause.)

Notes on Current Topics.

The Proposed Royal Academy of Medicine.

THE scheme to which we alluded some time since, having for its object the amalgamation of all the Medical Societies of London, has assumed a tangible shape under the auspices of the Royal Medical and Chirurgical Society. The Council of that Society has issued to its members a circular detailing the proposed construction of the Royal Academy of Medicine, as it is proposed that the new institution shall be called. Divesting the proposition of unnecessary details, it stands as follows:—

I. That a new Society be formed, and incorporated by Royal Charter, under the title of the Royal Academy of Medicine; and that this Academy comprise sections for the main branches of medicine and the collateral sciences.

II. That the following sections be formed:—

1. Medicine and Surgery.
2. Obstetrics.
3. Psychological Medicine.
4. Clinical Medicine and Surgery.
5. Pathology and Morbid Anatomy.
6. State Medicine,—comprising Epidemiology, Public Health, and Medical Jurisprudence.
7. Physiology and Anatomy.

Each section will entertain questions of Therapeutics, Chemistry, and Physics, so far as they bear on its special subject.

III. That the general management of the Royal Academy of Medicine be under the control of a General Council, consisting of a President, two Treasurers, two Librarians, two Secretaries, the Presidents of the various Sections, and additional members to be nominated one by each section.

IV. That all the members of the General Council, with the exception of the Vice-Presidents, who are *ex officio* members, be elected annually by the Academy at a general meeting.

V. That the President of the Academy be chosen annually from amongst the past or present Presidents of Sections, and be ineligible for re-election; and that the President of the Academy cease, on his election, to be a President of a Section.

VI. That the Treasurers, Librarians, and Secretaries, be elected annually by the General Council from the general body of the fellows.

VII. That the moneys, books, premises, and other properties belonging to any of the Societies which shall join in the proposed amalgamation, become the property of the Royal Academy of Medicine; and that the entire management of the funds of the Academy be in the hands of the General Council.

VIII. That all fellows or members of the following Societies, viz., the Royal Medical and Chirurgical, the Pathological, the Epidemiological, the Obstetrical, the Clinical, and the Medico-Psychological Association, be original fellows of the Royal Academy of Medicine without further nomination or election, provided they make the payments hereafter to be arranged.

IX. That power be taken by the Charter to incorporate additional Medical Societies after the proposed Academy shall have been formed.

X. That fellows, members, or licentiates of the Colleges of Physicians or Surgeons of Great Britain and Ireland; doctors or bachelors of medicine, or masters or bachelors of surgery, of the Universities of Great Britain and Ireland, or of the Colonies; members of the Faculty of Physicians and Surgeons of Glasgow; Licentiates of the Society of Apothecaries of London, or of the Apothecaries' Hall of Ireland; or foreigners whose qualifications are satisfactory to the Council; be eligible for admission into the Academy by nomination and election, as at present is arranged in the Royal Medical and Chirurgical Society; and that their recommendation be signed by three fellows of the Academy, two of whom, at least, shall be members of a section to which the candidate declares himself desirous of becoming attached.

XI. That in adjusting the scale of payments, consideration be had to the number of sections which each fellow may join, and for the privilege of using the library of the Academy and of receiving copies of the transactions and proceedings of the several sections.

XII. That deductions from future payments to the Academy be allowed for any admission or composition fees which may have been already paid to any of the Societies enumerated in Resolution VIII., as provided in the bye-laws of those Societies.

XIII. That any fellow, who shall wish to leave one section of the Academy and join another, may do so on the day of the annual meeting of the Academy.

XIV. That any registered medical practitioner, on complying with the regulations required, be eligible for election as an associate of the Royal Academy of Medicine on payment of an admission fee of one guinea and an annual contribution of one guinea, which shall entitle him to attend the meetings of any one of the sections, and also to a copy of the transactions and proceedings of such section; and that the manner of election of such associates be regulated by each section as it may think fit.

XV. That no present fellow or member of any of the Societies be required to pay the admission fee of one guinea.

XVI. That the members of each separate section elect annually the Council of that Section; and that such Council consist of a President, two Secretaries, and such number of other Councillors as shall hereafter be arranged.

XVII. That the Council of each section have the entire control of the internal business of their own section, and that they publish the transactions of their own section, provided the expenditure do not exceed one-half of the income derived from the annual subscriptions of the members of the section.

XVIII. That the proposed Academy comprise a grade of honorary fellows, consisting of the honorary fellows or honorary members of any of the enumerated Societies which shall join in the amalgamation, and others to be elected for life from British subjects who have eminently distinguished themselves in medicine or surgery or in the sciences connected therewith, but who do not practise the medical profession; and from foreigners who have eminently distinguished themselves in medicine or surgery or in the sciences connected therewith. That such honorary fellows be elected by the Academy at a general meeting, on the recommendation of the Council.

Should the scheme embodied in the above Resolutions be approved, the Council recommend that it be submitted to each of the Societies mentioned in Resolution VIII., and that they be requested to nominate three members each to form a General Committee which shall draw up, with legal advice, a code of laws and regulations to be submitted to each Society for its approval.

A Good Example.

A PRECEPTOR whom, in most matters, civilised Britons would probably regard as worthy of very little consideration, has this year shown us the plain road to the medical guardianship of the public, over which the House of Commons and the Medical Council have so lamentably bungled. While our Medical Parliament has been trying to excuse its timidity and indifference by throwing the blame on its means of action, the State of Minnesota has passed an Act which everyone can understand, and which, without the expenditure of money and chatter which the Medical Council costs us, will, we expect, secure to the inhabitants of the State and to the profession all the benefits which the Medical Council has NOT conferred upon the profession at our side of the Atlantic.

Sec. 1.—That it shall be unlawful for any person, within the limits of said State, who has not attended at least two full courses of instruction, and graduated at some school of medicine within the United States, or of some foreign country, or who cannot produce a certificate of qualification from some State, district, or county medical society, and is not a person of a good moral character, to practise medicine in any of its departments, or perform any surgical operations for reward or compensation, or attempt to practise medicine, or prescribe medicines, or perform any surgical operation for reward or compensation, within the said State of Minnesota.

Sec. 2.—Any person living in the State of Minnesota, or any person coming into said State, who shall practise medicine, in any of its departments, or perform, or attempt to perform, any surgical operation upon any person within the limits of said State, in violation of Sec. 1 of this Act, shall, upon conviction thereof, be fined not less than fifty dollars, nor more than one hundred dollars for such offence, and upon conviction for a second violation of this Act, shall, in addition to the above fine, be imprisoned in the county jail of the county in which such offence shall have been committed, for the term of thirty days; and in no case wherein this Act shall have been violated, shall any person so violating receive a compensation for services rendered: *Provided*, nothing herein contained shall, in any way, be construed to apply to any person practising dentistry exclusively.

Sec. 3.—No person who fails or neglects, on or before the first day of October, 1869, to file in the office of the Clerk of the District Court of the county in which he resides or keeps his office, a sworn copy of the certificate or diploma of some school or college of medicine, that he has attended at least two full courses and graduated at such school, or a sworn copy of a certificate of qualification of some State, district, or county medical society, shall be permitted in any court of this State to sue for or recover any compensation for his services, advice, or attendance as a physician or surgeon; and the failure to file a sworn copy of such diploma or certificate, as above provided, shall be *primâ facie* evidence that he has not attended or graduated at any school of medicine, or received a certificate of qualification from any State, district, or county medical society.

Statistics of Prostitution.

M. LEON LEFORT has availed himself of his two years' service in the Hôpital du Midi, to enter on a careful research of the statistics of prostitution in Paris, and of the different sources of venereal infection. His work on the subject, we learn from the *Union Medicale*, was communicated to the International Medical Congress of 1867, but has not been inserted on the record of its proceedings. The researches of M. Lefort prove that the greatest source of syphilis exists in clandestine prostitution, which is unfortunately, so difficult of repression. This is a very important consideration as bearing on the extension of the Contagious Diseases' Act to the civil population, for if the same causes existed to the same extent among ourselves, it would be obviously vain to hope for anything more than a partial repression of syphilis. The success which has atended the working of the Act in the army and navy undoubtedly suggests that clandestine prostitution is comparatively rare in England.

The London Hospital.

WE understand that, with a view to utilize more completely the extensive obstetric out-patients' department at this hospital, it has been arranged that a short course of six or eight clinical lectures will be delivered by Dr. Palfrey, especially intended to illustrate the more common forms of uterine disease, their diagnosis and treatment. We shall, from time to time, announce the days and hour upon which these lectures will be delivered.

Norwich Hospital.

THE new report of this charity speaks very hopefully. Two more wards have been completely remodelled, and many other improvements have been made in the year. There were 1,150 in-patients, of which 381 were accidents, in the house in 1868. The daily average was 120. The operations performed were 310, with only 10 deaths.

Hospital Physicians and Teachers in Medical Schools.

NOTHING can be more absurd than some of the laws or customs that prevail as to these appointments. Some charities are so jealous or so illiberal that they exclude their staff not only from joining rival institutions, but from various other posts, while others have taken particular care to deprive special hospitals from the support of those connected with them. A complication has arisen which brings this subject prominently forward. Dr. Beale resigned his chair at King's College, and is thereupon alleged to have resigned his physiciancy to the hospital, the one appointment being, it is said, included in the other. Could anything be more ridiculous? It is this exclusiveness which has injured so many schools. Why should a teacher of physiology be necessarily connected with any hospital? or, for that matter, why need he be a practising physician at all? Physiology was never better taught at University College and at the London Hospital than when Dr. Carpenter filled the two chairs and he did not practise. Perhaps Huxley is incapable of instructing freshmen. All the hospitals would do better if more clinical teaching was the rule, so that the staff did little else.

There is more than this to be said. No reason exists why a teacher in a medical school should not be on the staff of some other institution and *vice versâ*. We know some hospitals where there is enough liberal feeling to permit such an arrangement, and we have no sympathy at all with that spirit of jealousy which makes exclusive rules to the injury of individuals, and under the guise of an interest in a particular hospital. Charity is too sacred a thing to be dragged into such petty rivalries; and we hope King's College will be ready to follow the lead of larger and more liberal hospitals.

Dr. Beale may well occupy the post of physician to the hospital, though his professorship at one of our Universities induces him to resign the chair at King's College.

Sagar v. Lancashire and Yorkshire Railway.

WE have received a copy of this trial, which painfully illustrates how much "doctors disagree." The case is peculiar, inasmuch as a longer time elapsed after the accident before the claim was made than is usual, and the really important symptoms did not appear for many months. Mr. Brodhurst attributed the condition of the patient to injury to the spine in the accident, and it was intimated that Mr. Holmes agreed, although he was not called. Dr. Briggs, Dr. Spencer, and Dr. Roberts, of Manchester, who had all been consulted, gave similar opinions. For the defence, Dr. Bland Radcliffe, Dr. Noble, and Mr. Beevor, of Manchester, Mr. Arkwright, of Bowdon, and Sir Wm. Fergusson considered the case one of rheumatic inflammation. We are not at present going fully into the evidence. We only wish to point out the differences that may occur in men's opinions. We may have an opinion of our own derived from perusal of the evidence, but would admit that that opinion might be changed by careful examination of the patient. Such an examination we should much like the opportunity of making. We may, however, make one remark. Suppose the history of such a case to be given to a candidate at one of our public examinations. When such authorities differ so widely, would not the candidate, whatever his response, run an unfair chance of being referred to his studies.

The late Dr. Slyman.

THIS gentleman, the founder of the Montgomeryshire Infirmary and the consistent advocate of sanitary improvements, practised since 1828 in Newtown, where he had so endeared himself that his town-fellows made his funeral a public one. He was born in 1807, so that at upwards of three-score years he has passed to his rest, respected and beloved by all with whom he came into contact. Such a life is well worth living, and his memory will be preserved. Forty years of honourable labour in such a profession as ours is, indeed, something to have been permitted to fulfill amidst the respect of one's brethren and one's neighbours. Honour to all who thus honour themselves and their calling.

Pneumonia.

ALTHOUGH Dr. Hughes Bennett's paper, at the Medical Society of London, was read by the Secretary, to the chagrin of a number of gentlemen who had been attracted to the meeting by a report that the redoubtable professor would be present to defend his doctrine in person, it proved very interesting, and originated a rather animated debate. Dr. Bennett's views are well known, and he marshalled his figures so as to give great force to his advocacy of restorative treatment. Dr. Richardson defended depletion from the condemnation thrown upon it in the paper, and declared he "had seen blood-letting do good." Dr. Bennett's paper was presented to the *Practitioner*, in the new number of which it can be read by those who desire to have it verbatim.

Under Consideration.

THE Profession at large will be charmed to hear that the introduction of a Medical Acts' Amendment Bill is "under consideration." The fact is worthy of record, lest it might escape the memory of our readers that the Bill is still in this condition and lest they may nurture the hallucination that there is the remotest chance of its emerging from that abyss.

The profession will appreciate the utter hopelessness of the case when we tell them that the Medical Council is to meet the first week in June, and that the already semi-asphyxiated Medical Amendments' Act is to be smothered in illimitable talk. To the four winds with the Medical Amendment Bill! We want it not. Impeded by the obvious indifference and reticence of the Medical Council a measure passed by Solon himself must be useless and when we shall see the Medical Council ready to use the powers it has instead of hiding itself from the reproach of its duty, behind every legal impediment, it will be time for us to clamour for greater powers. Antagonistic in every movement which can be of real use to the profession or the public, the Council appears unanimous in but one determination to escape, if even a chink be found, from dealing with obnoxious topics or great responsibilities.

Let us hope that we may yet be allowed to throw our whole force into a much sought Medical Amendment Bill. A Bill which will "amend" the Medical Council and all its equivocatory vapourings out of existence.

Dublin Obstetrical Society.

THE next meeting of this Society will be held on Saturday, the 8th inst., at eight o'clock p.m., in the College of Physicians, when the first business will be the discussion of the remarkable papers read at the last and previous meetings by Dr. Evory Kennedy on puerperal fever, and lying-in hospitals.

We would remind the Fellows of the College that the society on getting permission to hold their meetings in the College Hall, passed a resolution inviting them to attend all their meetings, a privilege that many will, no doubt, gladly avail themselves of on this occasion.

Hereditary Disease.

THE theory of correlation of physical forces was first announced by Grove, in a lecture which he delivered at the London Institution, in 1842. He also suggested the application of this doctrine to some vital phenomena. Dr. Carpenter subsequently, in 1848 and in 1850, published able papers in support of the same views. Can the doctrine of a correlation of forces be applied to disease? Dr. Winn has recently published a treatise "On the Nature and Treatment of Hereditary Disease," in which he argues, that there is but one cause for a large class of hereditary diseases. He adduces striking cases, from his own experience, in which hereditary taint manifested itself differently in various members of the same family, and frequently even in the same individual. From these facts, which are familiar to most medical men, Dr. Winn has inferred the existence of a correlation of morbific forces. We believe Dr. Winn is the first who has made this induction, and if it be granted, the practical deductions which he has drawn from it are of the greatest importance. If, as he observes, there be but one cause of hereditary disease, it follows that there must also be but one general plan of treatment. Dr. Winn gives some valuable hints on the subject of marriage, based on his theory; he also enters on the question of hygiene, with a view of checking the development of disease in those predisposed to hereditary ailments. He lays great stress on prophylactic treatment in infancy and childhood, and on the selection of a profession in after life. Dr. Winn offers a few speculations as to the mode in which hereditary taint is transmitted from one generation to another; he combats the hypothesis of its being conveyed through the medium of the blood, and suggests that the deleterious energy is inherent in the molecules of the nervous system.

Whatever may be the conclusion arrived at, the reader of the little work in question will admit that Dr. Winn has stated his views with clearness, while he has done the service of putting them into the smallest possible compass.

A Surgical Prize.

THE Surgical Society of Paris has just announced th subject of the Laborie prize (£48), to be awarded in January, 1870:—"Point out, by the aid of clinical facts, the actual value of supramalleolar amputation from the following points of view: 1. The mortality consequent upon the operation. 2. On the different ways of performing it. 3. The usefulness of stumps in the act of walking. 4. The artificial limbs best calculated for these stumps."

Maternity Mortality.

Dr. Tracy, speaking of the comparatively small percentage of deaths in the Melbourne Lying-in Hospital at a recent annual meeting of the subscribers, remarked:—"Dr. Maund and himself said, when commencing twelve years before, that the plan condemned so strongly last year by Dr. Priestly and most other medical gentlemen, namely, the establishment of lying-in hospitals on the principle of general hospitals, by having the patients in large wards, must not be adopted in their hospital, and they would have the separate system, where not more than two or three patients would be confined in one room, or small ward. They adopted the latter plan, and had never exceeded more than two women in one room; indeed, they were so loth even to have two women in one room, that unless it was for want of accommodation they never had more than one. The patients, too, occupied three positions in the hospital, for until really ill they were kept in the principal building, and only went to the small ward, or room, when they were so; after which, in about a week they returned to the main building again. Had the results he had mentioned, been stated previously, and sent home with the statistics of the low rate of mortality for two or three years, it would have been said, "Oh, you have had a run of luck, we have had good luck occasionally too;" therefore the honorary medical officers had waited; but now they considered the subscribers might congratulate themselves, inasmuch as the institution had been established twelve years, and, although there had been 3,421 cases of accouchement in the hospital, only 41 deaths had occurred, leaving the small average of deaths of 1·2 per cent. They could not hope for any better result in the very best private practice; indeed, any medical practitioner would be very fortunate if he had not a larger per-centage.

An Irish Academy of Science.

The Royal Irish Academy has followed the example of the Royal Medical and Chirurgical Society of London, and has invited all the scientific societies of Dublin to its embrace. Many years ago the Academy was the supreme tribunal for all scientific researches in Ireland, and its Transactions contain intrinsic evidence that there was not only abundant scientific talent and ardour, but that the Academy was looked to as the proper recipient of scientific communications. By degrees and under the influence of some very enthusiastic antiquarians the study of antiquities become paramount, in so much that many of its scientific contributions fell away, and the academy acquired the irreverent cognomen of "The Rag and Bone Shop."

It is now hoped to retrieve this serious loss by inducing the various scientific societies to affiliate themselves with the academy. The proposition is that each society should become a section of the academy; that the subscription of two guineas should confer membership of all sections; and that grants for publication or other purposes should be made by the academy to each section. Unfortunately for the scheme, most of the Dublin societies are fairly flourishing. The Geological Society is comparatively rich; the income of the Natural History Society is always equal to its expenditure: the Zoological Society is in a chronic condition of impending bankruptcy; but its objects are not such as would be served by the academy. The Scientific Club is independent, and the Chemical Club is unpretending and contented. Under these circumstances we anticipate that the blandishments of the academy will avail little, for the societies are not likely to be disposed to sink their individuality by their alliance.

The Medical Council will meet this year early in June. We hope it may do something.

The annual meeting of the Royal Medical Benevolent College is fixed for next Tuesday, the 11th inst., when some important change of bye-laws is to be proposed.

We regret to have seen by the daily papers, that Mr. Stone, of the College of Surgeons, was the victim of one of those street outrages that have lately, to the shame of the authorities, been now frequent in London.

The past and present Fellows of the Chemical Society, lately presented a handsome silver tankard to Dr. Odling, F.R.S., at a banquet, to which they had invited him. This is a gratifying testimonial to Dr. Odling's valuable services as secretary for upwards of thirteen years.

The authorities at St. Luke's Hospital propose to combine the offices of Chaplain and Secretary. Though the clergy may be honest, they are not notorious for business capacity, and the management is almost certain to prove unsatisfactory.

The elections have come off at the Sussex County Hospital, and the old routine has not been disturbed. Dr. Taafe made a noble but ineffectual effort for reform. We trust he will not despair, but on the first opportunity renew his efforts.

The lady doctors are to have another chance on the Continent. Sweden will authorise a college for their instruction, arrange for examinations, and give them a diploma to place them on a par with male doctors. This is the last *on dit*. Well, Sweden is not a bad place for temporary residence, so there is a chance yet for some.

Dr. Gordon lately read an important and carefully worked out paper to a local Society on the Influence of the Army on the Public Health. We have not yet been able to find room for an analysis of it, but it shows amongst our army brethren a disposition to work and a capacity to impart the results of observation which promises great things for the service.

Messrs. Negus and Co., of Melbourne applied to the Lands Department for a lease of 320 acres of swamp land in the neighbourhood of Dandenong, for the purpose of breeding leeches. Twelve acres only have been granted. Messrs. Negus propose to stock the breeding ponds with leeches from the Murray, and calculate that in three years they will be able to supply any quantity.

Last week, Dr. Edwin Hearne, a thorough sanitarian, called the attention of the magistrates of Southampton to the intolerable nuisance caused by the non-removal of house refuse within the borough. With hot weather in perspective, this neglect was calculated to prejudice the health of the town to a very serious extent, and he hoped the matter would obtain immediate attention of the authorities. The magistrates, after listening to Dr. Hearne's statement, promised the required official interposition. The nuisance complained of is unfortunately, not peculiar to Southampton, and we are convinced that much might be done, in this direction, by the exercise of the undoubted prerogative of the medical man, even though he be not an "Officer of Health," and by the devotion of a very moderate amount of time and interest to local sanitary purposes.

The London Poor-law Medical Officers' Association has inaugurated a movement which is very complimentary both to the Poor-law and medical charities systems of Ireland, and to the administration of it by the profession. The quarterly meeting of the Association was held on Wednesday last, and the especial attention of the members was invited by circular to the details of the Irish Poor-law system, which appeared in our columns lately. The Council of the London Association have very strongly urged upon the attention of the members a vigorous support of the Superannuation Bill. In his address, the President, Dr. Rogers, said—

Reference was next made to the system of medical relief in Ireland. The essence of the Act in operation in Ireland was to secure efficient attendance on the sick poor both at their own homes and at the dispensaries; the provision of all medicines and appliances by the guardians; and the appointment of dispensers in all populous places, thereby economising the time and labour of the medical officers. Since the Act came into operation, zymotic disease has been most materially diminished, small-pox has been nearly annihilated, and sickness generally has been largely diminished amongst the working classes. Now, it had been asserted, in evidence before a Select Committee of the House of Commons—and the statement has never been shown to be erroneous—that 72 per cent. of pauperism depends on sickness; therefore they would not be surprised to learn that the beneficial operation of the Act was soon manifested in a marked reduction of poor-rates. The total expenditure fell from £937,556 in 1852, to £513,048 in 1859; and though from the operation of national causes it subsequently rose, still, at the date of the last report, the expenditure was less by £142,225 than in 1852. An objection that has been raised in reference to the effect of emigration in reducing pauperism was well met by a member for an Irish borough, who at once replied that of his own knowledge he could assert that they were not the pauper class who emigrated, but persons above them in the social scale. Comparing the two countries, Ireland and England, the case stands as follows:—

	Population.	Medical Relief	Total Expenditure.
Ireland.. ...	4,500,000 ...	£132,000 ...	£795,331
England...	20,000,000 ...	£272,225 ...	£6,959,840

The comparatively fair remuneration of the medical officers in Ireland is provided from the resources of a country which, relatively regarded, is extremely poor; whilst the niggardly payments made in England stand out in striking relief to the vast means of the wealthiest country in the world. At their last meeting it had been pointed out how the poor-rates in England and Wales had almost uninterruptedly mounted up, so that the mere excess of expenditure in 1867 was £2,062,000 above that of 1852. Returns of several unions, &c., were quoted to show that a niggardly provision for the sick poor was almost inevitably followed by augmented poor-rates. He (Dr. Rogers) would not travel over the same ground again, but would prove his case by statistics put in another way, yet drawn from similar sources, and which long experience as a workhouse medical officer enabled him to interpret correctly. He was prepared to show that, other things being equal, wherever there had been in a union or parish insufficient outdoor medical relief, that there, in the fifteen years ended 1867, was a steady increase of expenditure on in-door maintenance.

◆

Correspondence.

SUGGESTIONS IN MEDICINE.—No. IV.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Mr. Editor,—In my previous letters I treated of tubercles as well as of partial phthisis, and offered certain suggestions with regard to those conditions. I have now to consider the disease when fully developed and seated in both lungs, which is the ordinary condition of consumption as met with by practitioners. The lethal plant is no longer in a state of torpid hybernation. The wide-spread seeds of disease have germinated, and now display their well-known blossoms and fruit still immature. Is it possible yet to prevent this ripening, and thus despoil King Death of his wonted harvest? Now is the time to act. Soon it will be too late. The drama will be closed.

Let me describe the case fairly and simply. The patient is a young person of strumous constitution. Years ago, tubercles were discovered in the upper, subsequently, in the lower lobes of both lungs, sown broadcast throughout the tissues. After a time they softened, and small vomicæ were formed, attended with the usual symptoms. We are assured that there are now a great number of small abscesses in both lungs, more especially towards the apices, and a few large cavities can be clearly detected. The patient is suffering from confirmed consumption, and experience shows that he will soon die from the combined effects of irritation, exhaustive discharges, and insufficient aëration of the blood. It is quite true he may still be supported for a time by the remedies in vogue—the day of doom may be delayed—but when these temporary expedients are exhausted, he will sink into a premature grave.

Believing as I do that the means usually employed are not adequate to the emergency—albeit Heaven forbid I should endeavour to depreciate their real value—and believing that even in these desperate circumstances there is still a ground for hope, I venture to bring forward the following novel expedient.

Pathologically considered, this condition of confirmed phthisis depends on a number of strumous abscesses seated in the lungs. Yet such lesions heal in other parts of the body, why should they not do so here? Partly this is due to the peculiar tissue of the lungs, partly to their continued motion, but more especially to the want of a free outlet for the matter. When tuberculous matter is located in parts near the surface, in glands, for example, it is not generally fatal. Neither is it necessarily so when seated in some of the internal organs, for the pus finds its way outwards and is discharged. Here, and in all such cases, the enclosing parietes are soft, or do not offer any insurmountable impediment to the exit of the secretion. The grand condition for the healing of abscesses is here fulfilled. There is a way of escape for a fluid which, if retained, would burrow and extend in such wise as to be eventually fatal. The surgeon wisely makes it a rule to assist Nature in this strait, and as early as possible makes his incision. The essential thing he knows is to liberate the pus, and let it flow freely away. Again, he makes his orifice in the most dependent part, so that the abscess may be constantly and perfectly emptied.

Now let us consider the condition of phthisical vomicæ. They are doubtless abscesses like those elsewhere, but placed in circumstances quite of a peculiar nature. The tissue in which they are placed is of a soft, spongy character, especially favourable, I should think, for their extension. Its constant motion must form a serious impediment to the healing process. But the worst feature is, in my opinion, the great difficulty—hitherto amounting almost to an impossibility—of securing a proper drainage for the secreted and altered fluids. These, in old-standing cases, necessarily become corrupt in the extreme, and by their fœtid acerbity add greatly to the prevailing irritation. It is true there is an opening communicating with the atmosphere to each particular vomica, however small; to wit, that through the bronchi and larynx. But only consider how distant this is from the surface, and, besides, instead of being at the bottom, it is usually at the top of a series of cavities opening one into the other like a honeycomb. In the earlier stages, when the strength of the patient is unimpaired, we can believe that the vomicæ get occasionally emptied by expectoration; but afterwards, when the powers are exhausted by long suffering, *we know* that this is very rarely the case. The putrid fluids perpetually fall back into the lungs after each feeble effort for their elimination. There we can often hear them wash about, and can recognise the sounds which indicate the impediment they offer to vital aëration. Pray, are these favourable conditions for the healing of strumous abscesses?

Let us examine for a moment certain parts of the anatomy of the breathing apparatus. A diagram would show that the lungs with their appendages bear a great resemblance to a double flask with a very long neck; for there is no lower orifice to the lobes when enclosed in their serous pleuræ and bounded by the ribs and diaphragm. Their likeness to a bottle is therefore complete. The lengthened cervix to this imaginary vessel is surely well represented by the ascending bronchi passing into the trachea and larynx, and further extended by the pharynx and mouth. Through this long channel all the excreta must pass; and as they constantly gravitate backwards while they become putrid and acrid, they afford little chance for the healing of ulcers.

Attempts have been made occasionally, I know not how often, to remedy these evils by the formation of a dependent opening somewhere in the side of the thorax. When a large vomica has been known to exist near the surface of the lung, and it is believed that the two pleuræ over it are closely glued together by previous inflammation, a puncture has been made into the abscess between the ribs. This has been done in the hope that a healthful drainage might be established. Of the results of this operation I have no statistics. It may have been so far successful as to ensure the emptying of that one ulcer. But the infrequency of its adoption would seem to indicate that it was not generally approved of, or could be adopted without danger, for there is risk of wounding a large blood-vessel in the lung, and a chance of the putrid matter getting into the pleural sac, and thus exciting fatal inflammation. Let alone these drawbacks, to me the operation appears, even when successful, to answer but a doubtful purpose. The object is to drain the entire viscus. This would empty but one of the countless vomicæ that beset the lungs in far-gone phthisis. No wonder it should be abandoned as practically useless. Independent of the chance of injuring the patient, it offers but a trivial chance of relief. It is mentioned merely to show how great has been felt the necessity for a dependent opening for these, as for other abscesses. The aim is good—the means insufficient.

"What, then," it will be asked, "is to be done? There is no resource left except from medicine and hygiene. We must trust to them." Such would seem to have been the general conclusion; for no further effort of the same kind has been made of which I am aware. The case has been abandoned as hopeless.

Yet I have now to offer a suggestion that I believe to be quite original, and, moreover, I trust as effectual as new. Previous to doing this, and as an introduction, I will recall to the mind of your readers, Mr. Editor, a circumstance that occurred many years ago.

It may be remembered that the eminent engineer, Mr. Brunel, architect of the Great Eastern Ship and Great Western Railway, nearly lost his life through a half-sovereign getting into his windpipe. He was playing with his children, and put the coin into his mouth to amuse them. By some accident it got into the larynx, went down the trachea, and was supposed to lodge at the bifurcation of the bronchi. As this happened in London, of course the most eminent surgeons (and how eminent I need not say) were quickly in attendance. All known means to dislodge the intruder were employed in succession ineffectually. The operation of laryngothotomy was then performed in the hope that the golden disk would either be ejected through the opening, or its exact position be ascertained, so that it might be seized and extracted. But no good result followed. The coin remained much *in statu quo.* A slight change of position was supposed to ensue when the patient moved or coughed. Otherwise it remained out of reach and was not ejected. The sufferings of Mr. Brunel may readily be imagined, as well as the anxiety of his friendly attendants; for at any moment he might be seized with dyspnœa and die suffocated. Hour after hour passed without essential alteration. The resources of art were exhausted, and the minds of all were filled with the most gloomy forebodings. It seemed as if nothing more could be done. One surgeon after another left to attend to his other avocations. The patient was intrusted at length to the sole care of his unprofessional attendants—he was in a measure alone.

It was in this quiescent season that the mind of the great engineer worked triumphantly. The thought of his critical condition doubtless stimulated his great and original genius. He pondered on the nature of the accident, and providentially bethought him that as the half-sovereign got into his windpipe by gravitation, it might be dislodged by the same law of nature. In other words, it fell into his throat, why should it not be made to fall out again? The only thing necessary was to reverse the position of the body. At all events this was worth trial. The happy thought led to the saving of life.

The story goes, that before the arrival of the surgeons, Mr. Brunel had caused a light and suitable frame to be constructed. More probably this was the result of a consultation between the parties. At all events, he was laid upon the board, this was made to revolve, so as to throw the head and shoulders downwards, and almost immediately afterwards, he had a slight fit of coughing, and spat out the golden coin—the *fons et origo* of mischief—from his mouth.

One knows not which most to admire in this drama, the originality of the idea or the boldness with which it was carried out. An ordinary man would have been contented with the routine practice, and would probably have died under it. This man of genius hoisted the banner of independence, and happily conquered beneath its folds. Some credit must also be given to the liberal and enlightened men who made no silly opposition to the plan, but at once aided to carry it into execution. *Par nobile fratrum.* Others have since been benefited by the same means.

Now, my proposition is, that a similar principle should be adopted in cases of confirmed consumption as when heavy foreign bodies lodge in the air-passages, namely, that *the body should be temporarily reversed.* In early life this idea first occurred to me. When I read in the papers the above account of Mr. Brunel, I hailed it as a confirmation of my views. Here had a man of genius, albeit no physician, hit upon a novel, but certainly most natural and legitimate plan, for treating his own case, and he obtained the just reward. This, surely ought to encourage me to persevere in what I must consider, henceforth, a good cause. Ridicule and opposition must be met by patience and good humour.

At first, I tried the effect of a reversed position, as far as it could be obtained without apparatus. For this purpose I desired some bed-ridden phthisical patients to lean over the side, and keep the head on the floor for a few minutes at a time. This I found so far useful in promoting a free expectoration, that I determined to put the principle to a full and fair trial. Accordingly, I made drawings of a reversible couch, and consulted with Mr. Alderman, the well-known machinist, of London, as to its construction. Before, however, he had completed the design, I was obliged, through illness, to postpone the idea, and I have not since been able to work it out. The couch, half-completed, may still be seen, I dare say, in Mr. A.'s lumber room. *L'homme si propose, mais le bon Dieu si dispose.*

I will now, therefore, describe the nature of the apparatus, and how to put it in operation.

A frame-work, raised a few feet from the floor, should be so constructed that upon the turning of a winch one end of the mattressed couch in the centre could be raised or lowered to any angle with the horizon. If it could be done, I would have this regulated merely by the pressure of the hand, and held firmly in position by a rack or otherwise. At all events, I would have the power of bringing it to a level instantly a *sine qua non.* On this couch the patient could lie either on his back or his side, as might be most convenient. But broad bands would pass over his shoulders, and perhaps round his waist, to secure him firmly in his position, while this essential would be still further promoted by a stout leather covering, somewhat similar to a large gig-apron, which would cover in the lower half or more of his person, and be firmly buttoned to the couch. The arms would probably be free.

When all has been made comfortable and secure, I propose that the head of the phthisical patient should be gradually lowered, until perhaps, an angle of 45° is attained. The inhalation of watery vapours should then be practised, and expectoration encouraged. At first, probably, it would not be advisable to make the angle so great, or to continue it more than a few minutes. But, afterwards, I feel persuaded it could be safely borne for a quarter of an hour, two or three times a day. Of course, he would need to be carefully watched. If symptoms of distress were apparent, the position of the patient could be immediately altered or even reversed.

The benefits that may fairly be anticipated from this process, are, I think, incalculable. That which has always been considered so grand a desideratum, viz—a proper drainage of the vomicæ will be secured, and at the same time the sores will be kept clean, and free from irritating secretions. Although it may be impossible to give them rest, the abscesses will otherwise be put into the most favourable conditions for healing.

This desirable result may, at the same time, be promoted by medicine and all the ordinary resources. A variety of inhalents may be employed, especially of the astringent class, and it is then to be hoped that that cicatrization which nature sometimes effects spontaneously, may be frequently effected by art. Then will the triumph of the physician over this obstinate malady be complete.

Objections will, of course, be raised against this novel system of treatment. To some it may appear altogether preposterous and absurd. Such opposition has always been anticipated. Indeed, the proposition appears on the surface so singular and startling, that I cannot wonder it should be met at first by incredulity and ridicule. The idea of reversing the order of things, of turning the world upside down, &c., &c., &c., is sure to make certain people merry. Well, let them laugh. I bear in mind the words of Goldsmith with respect to the village preacher that full many

> "Who came to scoff—remained to pray."

The candid reader will, I trust, put aside his prejudices, and follow me while I mention one or two of the more obvious objections and the way in which these may be met and answered. In the first place, it will be said that it is impossible for any person, even in a state of health, to live for any length of time with the head downwards. This appears to me altogether a mistake. Young men and boys will at any time stand on their heads in a corner of the room for many minutes' duration. Clowns and pantaloons do so repeatedly. Then again, it is well known that there is a certain class of persons who make their living by frequenting low public-houses near town, and exhibiting themselves in this position, while they sing, drink beer, &c. I, myself, have seen a man, apparently of middle age, standing by the kerb, of a summer's evening, in Oxford street, London. Upon a mug of porter being brought from an adjoining hostelry, the fellow put a small iron tray down in the gutter, threw his legs up into the air, and while standing bolt upright on his head, drank off the liquor. Then, without changing his position, but encouraged by the half-pence of the bystanders, he sang a comic song with a loud voice, and beat time to it with the bare soles of his feet. I should think he was in a reversed position fully a quarter of an hour or twenty minutes, when he quickly resumed his natural position. He seemed none the worse for his exertion. His face was not particularly flushed, and he certainly spoke as if he could remain topsy-turvy by the hour. The dervishes and fakirs of India do something of the same kind, I presume, for long periods, from motives of religion. "Ah, but," it will be said, "these people are accustomed to this feat; they have inured themselves by degrees to the practice." True. So I should wish my patients to get acclimated. At first, the change of position would be slight, and maintained but for a very short period. I should also wish them particularly to begin when they were young, and before the disease was confirmed, so that they might be able to bear it well when most needed. Habit is said to be second nature.

It has been imagined that phthisical subjects are particularly prone to congestion of the cerebral vessels. If so, great caution would doubtless be required in reversing their position, especially at first. But I beg leave respectfully to doubt the fact. They are far from having ordinarily the short bull necks of those predisposed to apoplexy; on the contrary, theirs are usually long and slender; and when we consider the greater proportion of females to males subject to the disease, blood to the head may be considered rather the exception than the rule. Besides, if you examine carefully the class of people who practice reversion as a means of livelihood, you will find several of the tuberculous diathesis. The man I tell you of was suffering from some affection of the chest at the time of exhibition. Yet this did not disturb him. He coughed and expectorated freely while flourishing his feet in the air, and seemed quite at ease in that position.

Yours, &c.,
C. Toogood Downing, M.D.

Bath, April, 1869.

(To be continued.)

A CASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The following case came, a short time ago, under my observation:—I was called to see, as medical officer of this district, a female child, aged ten years, whom I found suffering from all the symptoms of the primary stage of *coxalgia* of *right* hip-joint. By appropriate treatment, at the end of six weeks, all the symptoms have disappeared. I then thought of getting her on her *feet* to see if she could use the joint with any ease, but on doing so, lo! and behold, I found the *left* thigh bone dislocated on the dorsum ilii. I should have mentioned that, during the entire time she was under treatment, she constantly lay on the left side, as this was the only position affording her any ease from the excruciating pain of right joint; and during all this time she never once, either to myself or the attendants, alluded to the left hip.

Now, Sir, I think this case is very interesting for more reasons than one, but especially as pointing out a danger to be avoided in the treatment of these cases, to which I never heard or saw any allusion made.

Yours obediently,
WILLIAM STEPHENS, M.D., &c.

Dunkineely, Co. Donegal, April 11, 1869.

P.S.—I may mention the right joint fully recovered.

◆

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows held recently, the following gentlemen, having undergone the necessary examination, were duly admitted members of the College:—Gould, Franklin, M.D. Edin., 26 Charlotte street, Bedford square; Kempthorne, Henry Law, M.D, Lond., Bethlem Royal Hospital; Legg, John Wickham, M.D. Lond., 11, South street, Park lane; Lackersteen, Mark Henry, M.D. St. Andrews, 28 St. Stephen's road, Westbourne park; Shaw, Thomas Claye, M.D. Lond., Middlesex County Lunatic Asylum, Colney hatch; Squarey, Charles Edward, M.B. Lond., University College Hospital; and Hope, William, M.B. Aberdeen, 42 Curzon street, Mayfair.

ROYAL SOCIETY.—The following is the list of candidates who have been selected by the Council for election into the Royal Society this year:—Sir Samuel White Baker, M.A., eminently distinguished as a geographer and explorer of distant lands; John J. Bigsby, M.D., distinguished as a geologist and palæontologist; Charles Chambers, Esq., director of the Colaba Observatory, Bombay; William Esson, M.A.. distinguished for his acquaintance with mathematics, physics, and chemistry; George Carey Foster. B.A., Professor of Physics in University College, London; William W. Gull, M.D., distinguished as a Physician and as a teacher of the Medical sciences; J. Norman Lockyer, Esq., of the Civil Service, author and editor of works on astronomy, and a large contributor to scientific literature; J. Robinson M'Clean, C.E., late President of the Institution of Civil Engineers; St. George Mivart, Esq., Lecturer on Anatomy at St. Mary's Hospital; John Russell Reynolds, M.D., Professor of Clinical Medicine in University College, London; Vice-Admiral Sir Robert S. Robinson, K.C.B., Controller of the Navy; Major James F. Tennant, R.E., late astronomer at Madras; Wyville Thomson, LL.D., Professor of Zoology, Botany, and Geology in Queen's College, Belfast; Col. H. E. Landor Thuillier, R.A., eminent as an Indian geographer; and Edward Walker, M.A., distinguished for his mathematical and literary attainments.

NOTICES TO CORRESPONDENTS.

SPECIAL NOTICE.

We propose in our next to recommence our investigations on the composition and uses of various "Foods and Drinks" most generally known in this country, of which we have not treated in former analyses. Our attention will first be directed to mineral waters, cocoas, mustards, &c. The gentlemen engaged in these reports are in the front rank of modern analysts, so that our readers may depend upon these reports for accuracy and impartiality.

Two communications are hereby acknowledged from Francis McEvoy, L.K.Q.C.P., M.R.C.S., Eng. 1. "A Worm discharged through an Abscess." 2. "Curious Exit for a Pin which was swallowed fourteen month previously."

We are favoured with an interesting contribution from Dr. I. P. H. Boileau, of the 29th Regiment, "On the Temperature of the Air in Upper Canada," which will appear as soon as space permits.

DR. J. A. BOLTON, Leicester.—The writer of the articles "Revelations of Quacks and Quackery," is not defunct or neglecting duty as you facetiously remark. The person calling himself Dr. Hammond, but, who in reality is known under various *aliases*, was exposed in these columns some four or five years since. The whole of these articles have been reprinted in the form of a pamphlet by the author, and form an excellent guide to the whole of the army of quacks together with their names, assumed or real, their modes of advertising and extortion. This unfortunately is, at present the only safeguard the public have. To put a stop to the abuse, of which the book-post is made the medium is simply impossible; as long as dupes are to be found, so long will they apply their objectionable avocations, and until the legislature shall step in, for the purpose of stamping out the plague, and give to the profession of Medicine the same protection as is obtained by members of the clerical and legal bodies; the public must be content that its letter-boxes should become the receptacles of the vilest class of literature that can possibly emanate from the press, and the profession satisfied, until its just claims to protection are heeded, with seeing patients thus grossly insulted as in the case in your note.

However, to expose this pseudo Dr. Hammond, Henry James Esq., or other alias, more than we have already done, would be a waste of space. We hear there is at the present time, an application before the Court of Chancery to restrain him by an injunction from advertising his sham electrical appliances to the detriment of the public and honest manufacturers. We sincerely hope this application may prove successful.

ERRATA.—In Dr. Palfrey's Lecture published in our journal on April [illegible]: at page 351, first column line 46, for, This again on the fifteenth day was *preceded*, read this again, on the fifteenth day was *succeeded*. In the second column at line 29, for that growth, read that *the* growth, and in the same column at the seventh line from the bottom of the page for "that the *women*," read that the *woman*.

In the last column of the lecture in the third line from the end "for the effects of the *flow*," read for the effects of the *slow* draining from their blood-vessels.

COMMUNICATIONS, enclosures, &c.. received from Dr. Birch, London; Mr. B[illegible]n, Ashburton; Dr. Hearne, Southampton; Mr. J. Lone, Brandow; Dr. J. Bolton, Leicester; Mr. Denman, London; Mr. Erasmus Wilson, London; Mr. Henry Grace, Bristol: Mr. Brooks, London; Mr. Collingridge, London; Mr. J. B. Curgenven, London; Dr. Furnival, Clapham; Dr. Palfrey, London; Mr. Tichborne, Dublin; Mr. Francis McEvoy, Balbriggan; Mr. J. Baxter Langley; Mr. Young, London; Dr. Wm. Stephens, Dunkineely; Dr. Pratt, Cardiff; Mr. D. B. James, London; Mr. Sampson Gamgee, Birmingham; Mr. Squire, London; Dr. Maunsell, Dublin; Dr. Forman, Chicago; Dr. G. Kidd, Dublin; Mr. Robert Freemans, London; Dr. H. Grainger Stewart, Newcastle; Dr. Johnson, London; Mr. R. Patchett, Ribchester; Dr. Pantaleoni, Nice; Mr. H. Sargeant; Dr. Quinan, Dublin; Dr. Brown, Taunton; Mr. Wright, Rhyl; Sir Ranald Marten, London; Dr. Drysdale, Dr. Williams, Dr. Clark, Dr. Davis, &c., &c.

DR. BARR MEADOWS.—The gentleman alluded to is—a copy of whose letter you sent us—or was a week or two since—upon the staff of the contemporary named.

MR. J. C. PROCTER, Lydd.—Is thanked.

EVANS'S ELATINE,

OR CONCENTRATED AQUEOUS SOLUTION OF TAR.

Beneficial in cases of Chronic Bronchitis, Asthma, Catarrh, Influenza, and Sore Throat. For Loss or Weakness of Voice it has a surprising action, hence its great value to Lecturers and Singers.

Dose.—A tea-spoonful to two-table-spoonfuls three or four times a day, alone, or in water. When mixed with milk or sugar and water it is very pleasant for children, or with the addition of the syrup of pine-buds. One valuable fact is, that it never disturbs the digestive functions, but, on the contrary, assists and promotes appetite. For Affections of the Chest, taken at bed-time in hot whey, it is especially effective

---

EVANS'S
ETHERIZED COD-LIVER OIL.

The addition of Rectified Ether to the Cod-liver Oil is of great value. In numerous cases where Sensitiveness of the Stomach exists the *Etherized* Oil is retained, and the digestive functions assisted for the purposes of nutrition. The pure Oil with Rectified Ether is bright and clear.

No. 1. Rectified Ether, 10 min. to each ℨij of Oil.
No. 2. Rectified Ether, 15 " " " "
No. 3. Rectified Ether, 20 " " " "

Lecture.

ON FIBROUS TUMOURS OF THE UTERUS.

By James Palfrey, M.D.,

Assistant Obstetric Physician to, and Lecturer on Clinical Obstetricy at, the London Hospital; formerly Obstetric Physician to the Farringdon Lying-in Charity, and to the Metropolitan Free Hospital, and to the Surrey Dispensary, &c., &c.

LECTURE III.

Gentlemen,—I shall ask you to give me your close and very earnest attention now that we have arrived at that most essential portion of our subject, "the diagnosis" of fibrous tumours of the womb; and I would not have you imagine that I desire unnecessarily to exaggerate the importance of each division of our subject as it passes in review before us. Is it possible, I ask you, to over-estimate the value of sound and practical knowledge upon these subjects? Can your ideas be too clear, or your views too well arranged, upon a class of cases of so great an interest to every one of you?

Let me show you by an example how deeply not only your own reputation, but also the well-being of a whole family, may be involved in an opinion you may at any hour be called upon to deliver. On the 16th of December, 1868, a lady was brought to my house for my advice by her husband. The history she gave me was briefly this: the patient was thirty-two years of age, married but seven months (a few years later in life, I will remark, than is judicious); up to the period of her marriage her health had been tolerably good; she had been regular; although her menstrual flow had always been abundant, lasting six and sometimes seven days, this flow was preceded generally, as well as succeeded, by a slight mucous vaginal discharge. Ten days after being married she menstruated, the period lasting seven days; she then missed two periods, and during this interval she first complained of lumbar pain, especially towards the latter part of the day, this distress being aggravated by walking. A few days later her breasts became tender and a little swollen, and some distinct fulness in her supra-pubic region followed these conditions; in addition, her digestion became disordered, and on three occasions she had rejected her food. Her general health also was visibly depreciated. After an interval of nine weeks from her last period, without previous warning of any kind, a considerable flow of blood suddenly appeared; it lasted three hours, then ceased; it was neither preceded nor followed by pain. A few days later this bleeding recurred, lasting on this occasion forty-two hours, but unaccompanied by any suffering. Advice was sought for her, and matters went on in much the same way until the time when I was asked to give an opinion as to her condition, the question being plainly put to me, "Is my wife pregnant or not?" At the time I saw her, the patient was a fairly healthy looking woman, of moderate stature, dark complexion, and rather thin; she expressed herself cheerfully. Proceeding to examine her, I found her breasts moderately developed, slightly painful when pressed; no fluid could be obtained from the nipple, nor was there either areolar to be seen, nor enlarged follicles present. Her abdomen was slightly prominent, and resonant on percussion; she distinctly complained of a pain in the right ovarian region, extending into the groin on that side. A vaginal examination revealed the following points:—Vagina of normal size, rather above normal temperature, bathed copiously with a mucous discharge; uterus rather low in the pelvis, and retroverted; the vaginal portion, which was slightly enlarged and hard to the touch, was carried upwards and forwards towards the symphisis pubis; it was tender and painful, and a little hard when pressed; the os tincæ of normal shape and size; the body and fundus of the womb, lying in the concavity of the sacrum, were distinctly enlarged, and in the posterior wall I found a small hard circumscribed growth, rather larger than a pigeon's egg. I at once concluded that this lady was "*not*," nor had she been, pregnant, my reasons for arriving at this opinion being these—had this patient been pregnant, and as far advanced (five months) as she and her friends suspected, and I must add hoped, the uterus would have risen out of the pelvic into the abdominal cavity, and its fundus would have been felt nearly midway between the umbilicus and pubis, such enlargement would have been equable; the tumour formed by the gravid uterus would have been soft and elastic, and at that period of pregnancy the fœtal heart would have been audible; the character of the bleeding, too, negatived the idea of the existence of pregnancy, for, assuming this condition to have been present, and that abortion was impending, the bleeding would have returned at shorter intervals, increasing in quantity, accompanied too with pain, all of which would have been succeeded, sooner or later, by the expulsion of the ovum. Nor did the amenorrhœa at the onset negative the opinion I had formed, for *irregular* and even scanty menstruation are frequent symptoms of commencing engorgement. Again, the neck of the uterus would have been much softer had pregnancy been progressing, and in a normal state the cervix is not either sensitive to the touch nor tender on pressure, both of which symptoms were complained of in this lady's case; and in those cases of retroversion occurring during pregnancy, it is rare indeed for the patient to go on to five months without getting symptoms of retention of urine of greater or less urgency.

Passing these points rapidly in review, I had no hesitation in advising this lady to discard all idea of pregnancy, and I pointed out to her that she was the subject of a condition requiring a little care which, although, in all probability present, some time before marriage had not given us any evidence of its presence until the change in her social state had been followed by uterine congestion, and the result justified the opinion, for under appropriate treatment, her uterus was relieved of its engorgement; her version was in a great measure remedied, and a few weeks since she informed me she was menstruating regularly for five days and was in improved health. Let us, before dismissing this case, consider how prejudical to this patient an error in judgment must have been, months of suspense followed by inevitable disappointment would have been the least of the attendants evils, for during that time her uterine congestion would have become confirmed, her version obstinate, and her general health shattered and deteriorated by this local disease. Yet, the rules which guided me to a safe conclusion in this simple case are plain and easily to be understood, and I trust not one of you will leave this hospital without being thoroughly at home in every single point in the diagnosis of female diseases. With this digression, let us proceed to the consideration of the diagnosis of these fibrous tumours of the uterus, and first let me observe gentlemen, that with few exceptions, as soon as a fibrous body has attained the size of a tangerine orange, it is without difficulty felt by palpation through the abdominal walls, and, in examining the uterus, by this means be careful that you get the organ fixed between your finger, of one hand in the vagina, and your other hand in the hypogastrium, by this means you can, with comfort examine the whole surface of the womb. Of course, you will remember that its detection by this means will be rendered more or less easy according to the position of the growth, for it will be evident to you that the nearer the fundus uteri the neoplasm is situated the more readily will you be enabled to grasp it through the abdominal walls, and the lower the tumour is developed in the uterine tissue the more care will be required in its detection by this means. The size also of the growth will have much to do with the facility with which you will be able to recognize these tumour when palpating, and it needs no demonstration from me to convince you that the presence of a large sub-peritoneal growth by its irregular and mammilated surface will be more readily ascertained, than an interstitial or sub-mucous body; these latter growths being much more deeply situated, in fact, being hidden in the one case within the uterine wall, and in the other, within the cavity of the organ, so that they are at times with great difficulty made out. Again, the texture of the tumour will assist you when practising palpation, for the hard dense unresisting fibroid will be easily distinguished from every other kind of tumour found in a similar position. Again, the cases in which these growths are multiple will be much more readily diagnosed than those in which but one tumour is present, for in these instances of multiple fibroids the irregular borselated surface of the several outgrowths combined with the stony hardness, and *as a rule* their position in the median line are signs pathognomonic of fibrous tumour of the womb. Once more, a point of difficulty will arise when you are diagnosing one of those rare cases in which a cyst has been developed in the centre or near the surface of a fibroid, or if a hard growth should become œdematous and swollen, this latter condition being anything but unfrequent. But bear in mind when examining the abdomen in cases of uterine tumour, that it is not in every case that a fibrous growth presents the irregular mammilated surface I have just been speaking of; sometimes they are smooth externally. And now proceeding to a vaginal exploration, you will find the results of your examination depend wholly on the position and depth in the wall of the womb, the size and density of the growth found in the particular case you are called to investigate. A very small tumour indeed, for instance, one not larger than a filbert may be readily discovered by vaginal examination as a hard and circumscribed body, when situated in the lower portion of the uterine wall, immediately beneath the peritoneal covering, but a growth of the same kind and size developed in the superior portion of the womb will be with difficulty diagnosed. You will recal a remark made to you in my first lecture, that as interstitial or submucous fibroids increase in size they encroach after a time upon the cavity of the body, and subsequently upon that of the cervix also. In diagnosis you will find this fact of some value to you, for although in the cases of the second and third and varieties of growths, this condition is invariably found; yet in the majority of cases of sub-peritoneal tumours, no alteration of the cervix whatever takes place, or should hypertrophy from increased nutrition result, it is by no means proportionate to the size of the tumour you find upon examination to be present. This fact will be proved by the use of the sound. Remember also, that if the tumour be situated in the parenchyma of the uterus, or if being sub-mucous, it protrudes into the cavity of the organ, you will always find an increase in the length and breadth of the lower portion of the womb, and just in proportion as the uterine cavity becomes filled and stretched by the tumour within it, so in proportion will the infra vaginal part of the neck become less and less in length, until, should the growth attain to a large size, say to that of a fœtal head at birth, the mouth of the uterus becomes dilated, and you will readily be enabled to introduce your finger into, and around, the lower segment of the cavity. Such an instance we had under observation here for a long time, and in which the thin and dilated os uteri presented the identical appearance, we find present in those cases of labour which are prolonged by the condition known by the term "rigid os." You must expect too, to find the cervix displaced soon after a fibroid has attained such a size, that by its weight it causes the body and fundus of the organ to tilt towards the side of the pelvis, coresponding to that in the uterus in which the tumour is located, for then the cervix is found in a position in the pelvis exactly opposite to that of the growth, and this deviation in position remains the same until the tumour, having so far increased in size, it comes in contact with the wall of the pelvis, and, then it pushes toward the opposite side,—the upper portion of the womb to which it is attached. Assuming that nothing occurs to prevent the still greater developement of the neoplasm, it will eventually fill up and occupy the whole pelvic cavity. There we find the uterus still more displaced, or even should it have contracted adhesions to any portion of the pelvic wall and so unable to rise, it will be found flattened against one or other wall of the pelvis, and so dragged out of position and shape that the discovery of the cervix is a work, at times, of considerable difficulty, and when the increase becomes so profound that the tumour can no longer be contained within the pelvis, and no adhesions be present, then the whole uterus rises into the abdominal space, stretching, narrowing, and distorting the upper part of the vaginal canal. Now this enlargement in the size of the whole uterus is attended with an increase in the depth of the cavity of the organ, and the presence or absence of this condition is demonstrated by the use of the sound, and in no uterine disease is this adjunct to diagnosis more valuable, the increased depth and breath being proportionate to the size of the fibroid. Let us suppose that a fibrous body is present in the posterior wall of the womb—by introducing the sound into the uterus and a finger into the rectum, we can with precision ascertain the size and thickness of the growth. Need I caution you, however, under no circumstances to make use of the probe if there exist a suspicion of pregnancy. Not only the uterine sound, but the stethescope also comes to our aid in the diagnosis of these hard tumours, for very frequently, but by no means always, you can hear over some portion of the uterus in which a fibroid is contained a *bruit de soufflet*. Bear in mind, however, that this murmur, or whiff, or whatever other sound to your ear it resembles, is synchronous with the patient's pulse; unlike that of the fœtal heart, it consists of one single sound only, and that it is usually audible towards one or the other inguinal region. Let us next briefly pass in review the various diseases and conditions that may be mistaken for the fibrous tumours, and the remark I have so often made in the out-patients' room gentlemen, although so familiar to most of you, I will repeat, that, although the diagnosis of the majority of cases of fibroids that come before you will not be a matter of difficulty or anxiety to you, yet now and again instances will occur in which all your acuteness, all your patience, and all your judgment will be required to enable you to arrive at a right conclusion; and first on this point, let me say that the most frequent error in practice I have myself committed, and the most common fallacy I have seen happen to others, has been that of mistaking a version or flexion of the uterus, in a congested state, for a fibroid, and seeing that the posterior is far more often the seat of these tumours than the anterior wall, notably a retroversion or retroflexion of the uterus is not unfrequently taken for a fibroid in that locality. You will avoid making this mistake in diagnosis if you bear in mind always that, notwithstanding the fact that in both conditions there exists a hard tumour, which is felt behind the superior portion of the vagina, and which moves with the uterus, yet if you discover a sulcus between the tumour and the cervical portion you may pretty safely conclude the case is a flexion, for fibroids are, as I have so often told you, developed higher up towards the fundus of the organ than the position in the neck, at which a flexion is found. But again, you will find the uterine probe will guide you to a truthful opinion, still I will not quit this point without reminding you that, hæmorrhage, mucous discharges, uterine colics, and vaginal tenesmus are alike symptoms of fibroids and flexions. Your difficulty, however, in forming an opinion will be lessened if you remember that the uterus in which a fibroid is situated is less moveable than the organ that is simply displaced, and that by the touch we do not meet with the sulcus I have spoken of, as we do in flexion, even if we, by the finger, follow the outline of the womb from the neck to the portion in which the fibrous body is situated. Should the growth be too high for your finger to traverse, palpation will, as I have already pointed out to you, prove a valuable means of assisting you in forming an opinion; on this important point another thought occurs to me. If you pass a sound into a displaced uterus (not always a safe or judicious proceeding, gentlemen), upon attempting to replace the dislocated organ, the tumour disappears, and your exploring finger no longer is able to feel the fundus; but it is otherwise if a hard growth be present: in that case you will not lose the tumour. Should no adhesions exist between the surfaces of the peritoneum, you may move the mass, but the growth will still be accessible. Next, I must tell you that fibrous polypi may easily be mistaken for submucous growths, or even interstitial fibroids; but as I purpose devoting a lecture to the study of these pedunculated fibrous bodies, I will postpone all I wish to say to you on this point until that occasion. Very often we find ourselves mistaking that very common affection (for which I know no better name than that given by Scanzoni—chronic parenchymatous inflammation of the womb)—for fibrous tumours of that organ, and you must exercise great caution in giving an opinion in every case in which the history has approached to this disorder. Be guided by these facts—in fibroids the menstrual flow is copious and prolonged, the pain is of a very different character also; in chronic engorgement often the period lasts but a few hours, and even then is scanty in quantity. Again, call to your aid the hints I have given you respecting the ovoid form and large size of sub-peritoneal tumours and their mammilated and irregular surface. While the enlargement of the cavity, and the distention and expansion of the cervix, conditions generally present in cases of interstitial and submucous growths will guide you to a safe opinion; for in every case of old inflammatory infiltration of the neck, that portion of the womb only becomes enlarged and hypertrophied as well as hardened. Gentlemen, the cases in which fibrous bodies take their origin in the cervical portion, are so exceedingly rare indeed, I have never seen an instance, that it would be taxing your patience unprofitably if I were to weary you with entering into the points in the differential diagnosis of these bodies and cancerous deposits commencing in the neck in the same position; but, leaving that point, it will be well of you to remember that the remains of an old pelvic abscess, or the thickening that results from a pelvic cellulitis, may be mistaken for a fibroid. Enquire carefully and the previous history will guide you. The delivery, or abortion which preceded the swelling—the association of the hectic which accompanies pelvic abscess—the difficult and sometimes impossible locomotion, will all help to lead you to the true nature of the case. Again, these conditions will give rise to a tumour far less sharply defined, more soft and elastic, and smoothe upon the surface than a fibrous body. Once more; I have occasionally seen tumours of the ovary, mistaken for hard fibrous growths of the uterus; and in these instances also the greatest care will often be required to prevent you getting upon a wrong track; for you all know that in the stroma of the ovary there are developed tumours of a complex character; and of these, notably malignant, cysto-sarcomatous, or fibrous growths, by their shape and density and irregular outline, closely resemble uterine fibroids, it will help you to remember that pain is not a symptom of ovarian disease, at any rate, not until the ovarian tumour has attained a very extensive development; and at the present time you can see among my patients an old lady who is the subject of well-marked and extensive cancer of the ovary, but it was not till recently that her pain was sufficiently great to demand from us the administration of sedatives, although some months have elapsed since she first came under our observation. Again, the catamenia are seldom either irregular or prolonged in early ovarian disease, both of which symptoms, I have shown you, are almost invariably present in cases of fibroids; and it is not at all uncommon for women to be for a long time under treatmen with ovarian cysts of large size, who have at no time complained of leucorrhœa. Again, in ovarian disease, the displacement of the uterus, that is caused by the presence of the tumour, is towards that portion of the pelvis *opposite* to which the diseased ovary is located. At other times the vaginal portion is wholly beyond our reach by reason of the tumour, in its development, having dragged the womb completely out of the pelvis into the abdominal cavity. Again we do not find the fluctuation present in uterine fibroids that almost invariable forms a prominent diagnostic sign in ovarian disease. (I except from this statement those very uncommon cases of fibro-cystic disease of the uterus that I have already spoken of.) The gradual development and increase of the ovarian tumour *in one or other inguinal region* too is absent in fibrous tumours of the womb, and until an ovarian tumour has attained considerable dimensions the os and cervix are not altered in size or shape, this remark you will at once perceive does not hold good when a growth is in the uterus, and the increase in the length of the cavity of the womb, which, in interstitial and submucous growths, is so readily made apparent by the sound, is absent in ovarian tumour, at any rate until the latter disease is of such a size that it could not possibly be mistaken for a fibroid. The careful examination of a few of these cases will enable you also to recognize the undeviating relation that exist between the uterus and the fibroid and this is absent in ovarian disease, for in the latter the tumour is, generally, easily to be isolated from the womb. Another point too will help you, ovarian disease is much more rapidly developed than these hard uterine tumours of which I am speaking. These ovarian cases are at times, however, very puzzling; and I advise you, whenever a reasonable doubt exists in your minds as to the nature of a given case, to suspend your judgment; think on the conditions present; renew your examination until calm, and it may be prolonged deliberation have enabled you to solve the problem. I have in this lecture already touched upon the diagnosis of fibrous tumours and pregnancy, so that but few words are needed upon this head. Remember that a pregnant uterus, when manipulated with the hand, contracts, and the outline of the uterus, upon visual examination, becomes distinct. To Mr. Ingleby we are originally indebted for the mention of this fact. This does not happen to the uterus in which a fibrous body is contained. In pregnancy, too, the uterus increases in size far more rapidly than happens in fibroid growths, and in the cases we have under consideration the recurrence of menstruation—the absence of mammary signs—the absence also of that universal purple hue of the vagina which is always present after the fourth or fifth month in pregnancy, all assist in negativing the idea of pregnancy. I think, gentlemen, I have now placed before you most of the practical points that it is essential for you to carry in your minds in reference to the diagnosis of these hard growths of the uterus. When we next meet I propose, after saying a very few words indeed upon the prognosis of fibroids, to go into the subject of their treatment.

Original Communications.

ON THE COMPOSITION OF THE MILK OF THE SOW.

By Professor Charles A. Cameron, Ph.D., M.D.,
Analyst to the City of Dublin.

With the exception of the milk of the sow, the lacteal secretions of the domesticated animals have been repeatedly analysed. Scheven appears to have been the only chemist who has published an analysis of sow's milk; but his results are so different from those of an analysis of sow's milk made by myself that I am induced to publish my analysis. In the sow's milk examined by me there was six per cent. of fat, whilst in a specimen analysed by Scheven, the proportion of that constituent was under two per cent. It is not very easy to procure a specimen of sow's milk, and perhaps this is the reason why it has not hitherto been frequently analysed. I endeavoured on several occasions to obtain a small quantity, but the sows appealed to at my instigation were obdurate—they would not yield a drop, even when subjected to the dexterous manipulation of the most skilful dairymaids. At length, about two months ago, a specimen of sow's milk came into my possession: I am indebted for it to Thomas Baldwin, Esq., the Superintendent of Irish Agricultural Schools, and Director of the Glasnevin Government Model Farm, On submitting it to analysis the following results were obtained:—Specific gravity, 1,041; colour, white, without any bluish shade; flavour very rich, resembling that of the skimmings of cow's milk; reaction, very faint alkaline.

100 parts contained:—

Water	81·80
Fats	6·00
Casein and other nitrogenous matters ...	5·30
Lactin	6·07
Mineral matter	0·83
	100·00
Total solids	18·20

The analysis was conducted as follows;—

A. A weighed portion of the milk was acidulated with a little acetic acid to prevent the formation of a skin, mixed with pulverised quartz (which had been previously boiled in hydrochloric acid, washed and ignited) and evaporated in the water bath to dryness.

B. The residue was treated with strong ether, by which the fats were dissolved. The ether was then evaporated and the residue of fats weighed. The fats were finally burned in a platinum capsule, and left no residue, proving the absence of mineral matter or casein.

C. The substance from which the fats had been removed was subjected to a nitrogen combustion, and from the amount of nitrogen obtained the proportion of casein and other nitrogenous substances present in the milk was estimated in the usual manner.

D. The proportion of lactin was found by difference, and also by the sulphate of copper method.

E. Determination of the mineral matter (ash) 5 grammes of the milk were evaporated to dryness and the residue burned in oxygen gas. The amount of solid matter obtained by desiccating a weighed quantity of milk was slightly in excess of the sum of the weights of the individual constituents. It must, however, be borne in mind that the mineral matter in the nitrogenous substances is weighed twice—first as a constituent of the casein, and, secondly, as an ingredient of the ash. Its amount, however is trifling.

A comparison of the milk of the sow with that of the cow and other animals will show how extremely rich is the former.

Composition of the milk of different animals.

1,000 parts contain—

	Water.	Butter.	Cheesy matter.	Sugar.	Mineral Matter.
Woman ..	889·08	26·66	39·30	48·68	1·30
Cow ..	864·20	31·30	48·80	47·70	6·00
Goat ..	844·90	56·87	35·14	36·91	6·18
Ewe ..	832·32	51·31	69·78	39·43	7·16
Mare ..	904·30	55·26	33·35	32·76	5·23
Ass ..	899·12	28·53	35·65	50·46	5·24
Sow ..	818·00	60·00	53·00	60·70	8·30

Proportions of Solids and Water in different kinds of Milk.

	Woman.	Cow.	Goat.	Ewe.	Mare.	Ass.	Sow.
Water	889·08	864·20	844·90	832·32	904·30	890·12	818·00
Solids	110·92	135·80	155·10	167·68	95·70	109·88	182·00
	1000·00	1000·00	1000·00	1000·00	1000·00	1000·00	1000·00

The following particulars relative to the sow whose milk I have described were furnished to me by Mr. Baldwin:—"The sow whose milk I sent you is a pure Berkshire; she had pigged six days before the milk was withdrawn; she has a fair litter, and is an average nurse. She is receiving the sort of diet suited to her condition, namely, a mixture of small and damaged potatoes, pulped roots, and a little grains, the potatoes and roots being subjected to the action of steam. The food is not too rich, but just sufficient to keep herself and her young in a good healthy condition."

Pig's milk is extremely rich, containing, as it does, nearly 50 per cent. more nutritive matter than is found in that of the cow. It is not unlikely that in certain forms of disease where a milk diet is prescribed the use of so concentrated a liquid food might prove serviceable.

◆

ON SOME POINTS OF INTEREST CONNECTED WITH THE EPIDEMIC OF MALARIAL FEVER OF MAURITIUS IN 1867.*

No. II.

By Wilmot H. T. Power,

Assistant-Surgeon, 2nd Battalion, 18th Light Infantry.

Varieties of the fever.—I have ventured to classify them as follows :—

Family.	**Malarial Diseases.**
Genus I.—*Feb. mal. continua*	Species 1, *mild* (syn. febricula.) „ 2, *severe*.
„ II.—*Feb. mal. intermittens*	„ 1, *quotidian*. „ 2, *tertian*. „ 3, *quartan*. „ 4, *irregular*.
„ III.—*Feb. mal. remittens*	„ 1, *simple*. „ 2, *bilious*.
„ IV.—*Malarial collapse*	Sign, feb. mal. perniciosa.
„ V.—*Malarial cachexy*	Species 1, *without* structural changes in tissues of body. „ 2, *with* structural changes.

The *mild continued malarial fever* was especially prevalent in November and December, 1866, prior to the outbreak of the epidemic, and it seems probable that the ordinary "*febricula*" of hot climates is due to a very small dose, as it were, of the poison.

The *severe continued malarial fever* presented the same symptoms as have been often described before.

The varieties of *intermittent* were also just as they occur in other countries, quotidian being by far the most frequent form, and tertian next.

The *remittent fever* did not prevail much amongst the men of the 13th. As to the so-called "bilious" form, I saw no cases in my regiment ; and I cannot help fancying that it is a mixed disease—viz., actual malarial fever, occurring in a person who has previously been thoroughly malarialised, and especially if his previous attacks of fever have been untreated.

Malarial collapse.—The main symptoms are, sudden coma, with dilated pupils and coldness of body, in a person who has had an attack of ague, severe or mild ; he is, in fact, convalescing, but not so rapidly as he ought ; he complains of literally nothing but weakness. Five such cases occurred in the 13th ; the first was not treated with quinine, and died ; the other four recovered well, though almost pulseless, cold, and comatose when the quinine was administered. The *post-mortem signs* were, a huge spleen, and a profound anæmia of all other parts of the body ; veins and arteries empty of blood ; no congestion anywhere ; a small yellow clot in right side of heart. I have been unable to consult many authorities on this subject, and have not seen any account of this form of disease. The absence of fever, with the suddenness of the coma, render it extremely dangerous. In two of my cases the orderlies supposed the men to be asleep.

Period of incubation.—Thirty-six men escaped the fever, and of these two had the first attacks of ague in England, six months after leaving Mauritius.

Causes of relapses.—From meteorological observations taken for a year after the arrival of the regiment in England, I cannot but conclude that the cause of relapses is a fall of temperature, especially if sudden, mere dampness having no effect ; in other words, damp warm weather, such as the last two winters, is unfavourable to the occurrence of relapses. And this is of practical importance in regard to the question of sanitary stations for malarialised men, for undoubtedly for the first few years what is called a fine bracing air is *not* the best, but rather a warm equable climate. As is well known, fatigue and exposure greatly tend to bring out the fever in men who have been exposed to malaria ; and this was well shown when the regiment went to Flat Island (where there was no malaria), for they were knocked down by fever far more frequently then than when they were in Port Louis, in the very heart of the fever districts ; but in Port Louis they were indoors all day, and had scarcely any duty and were well fed, whereas in Flat Island all these conditions were reversed.

Thus, then, the cause of a relapse or of the actual fever in a malarialised person would seem to be any agent or agents which produces a *depressing* effect on the system.

Treatment.—Quinine, in doses of twelve to thirty or forty grains ; no emetics, no purgatives, "no clearing out the primæ viæ" was found necessary. Arsenic, quinoidine, &c., were tried, but were found to be uncertain in action.

Occurrence of dysentery.—No such disease as malarious dysentery occurred—in fact, though a very dangerous and fatal dysentery attacked the regiment at Flat Island (where there was no malaria), those men who were left behind in Mauritius, in the fever districts, did not at all suffer from it. Ipecacuhana was of no use in this form of dysentery, but the tinct. ferri perchlor., in doses of from 200 to 600 minims per day, acted like a charm.

HOSPITAL PHARMACOPŒIAS.*

Mr. Squire, whose labours in this direction have so often obtained the commendation of all concerned, is not satisfied with the success he has obtained with his work on the British Pharmacopœia, and has now reduced to order, and gives us in one neat handy volume the pharmacopœias of seventeen of the Metropolitan hospitals. The forms thus collected are managed in groups for easy reference and comparison, and will be useful to not a few of our brethren. Here they will find the approved prescriptions of our metropolis, as adopted for hospital use, where elegance has sometimes to give way to economy. We should think Poor-law and Dispensary medical men would find the work particularly useful. The book is "got up" in a manner to make it a worthy supplement of Mr. Squire's former and more important work.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON,

May 3rd, 1869.

Peter Marshall, Esq., President in the Chair.

Dr. Leared showed a

STOUT GLASS TONGUE-DEPRESSOR,

made by Pearce and Co., of Oxford street, its superiority over the metal ones is its greater cleanliness, and the ease with which it can be cleaned.

Dr. Richardson brought forward a

LAMP FOR THE SICK ROOM,

made by Mr. Jones of Aylesbury, from suggestions by R. Ceely, Esq., it is particularly suited to the wards of hospitals, giving both light and heat, and being capable of boiling or keeping warm water, &c., it is also very inexpensive.

---

* Read before the Army Medico-Chirurgical Society of Portsmouth, March 3, 1869.

* The Pharmacopœias of Seventeen of the London hospitals. By Peter Squire, F.L.S. London : J. Churchill and Sons.

The SECRETARY then read a paper by Dr. Elliott, of Hull,

ON THE EFFECTS OF TOBACCO AND NICOTINE ON THE GOAT.

In experiments he had made he found that an ounce of shag tobacco eaten from his hand by a goat had no effect at all, he then injected beneath the skin of the neck ten minims of nicotine, violent symptoms were produced in thirty seconds, loss of power in limbs, hurried respiration, muscular tremor, pulse rose from 80 and 90 to 160, death momentarily expected, but in twenty hours after the operation the goat was quite well again. Dr. Elliott considered that the complete loss of power when sensation was unaffected and the heart's action strong, has a practical bearing favouring the opinion of Professor Haughton that nicotine is the best agent we possess for the treatment of tetanus and poisoning by strychnia.

A discussion then took place in which the President, Dr. RICHARDSON, Mr. MILLER, and Dr. LEARED joined.

An interesting paper by Dr. LOWE of Lynn, on a case of

ENCEPHALOID DISEASE OF RIGHT KIDNEY,

was then read, in the discussion of which Dr. HARE, Dr. THOROWGOOD, and Dr. RICHARDSON took part, regret being expressed that time did not allow of its being more fully entered upon.

The thanks of the society were unanimously accorded to Dr. LOWE, and Dr. ELLIOTT, for their valuable papers, and to Messrs. JONES and CEELY, for the lamp communication.

Summary of Science.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

(Specially Edited and Compiled for the Medical Press and Circular.)

BY C. R. C. TICHBORNE, F.C.S., M.R.I.A., ETC.

TWO NEW ELEMENTS.

SOME time since, Mr. Church observed some curious absorption bands produced on viewing zircons from Ceylon. Mr. H. Sorby attributes the bands to the presence of a peculiar earth, which he names jargonia. In a letter addressed to the editor of the *Chemical News*, dated April 13th, he states that he has discovered spectrum evidence to prove that independently of jargonia, zircons from different localities contain two distinct earths, occurring in variable proportions, so that some appear to contain little or none of one and others to be chiefly composed of it. However, until we know a little more of the chemistry of these two supposed elements from the investigations of Messrs. Sorby and Church, it would be premature to consider their existence definitely proved.

"CATHARISM."

UNDER this name Mr. Charles Tomlinson describes phenomena which he has been investigating for some years. The term is used in this sense by the author: a surface is said to be catharised when it is chemically clean, which differs from what we understand by clean. The very substances which would ordinarily be used for cleaning a surface would indeed *de*-catharise the surface. "The term 'molecular change,'" says the author, "is, according to my views, a vague one in physico-chemistry; the term 'catharised condition' has, at least, the merit of clearness. The Greek word signifies pure, or clean, but is very different from what is ordinarily understood in the application of 'clean.' It is a well-known fact that bodies in the ordinary state separate as nuclei, gases, salts, or vapours from solution. Thus, if a wire, rod, or other solid substance is placed into an effervescent fluid, it is immediately covered with gas upon its surface, &c." Liebig, Oested, and Schönbein, and Gay Lussac, had investigated the phenomena connected with this subject, but their explanations do not seem satisfactory. Mr. Tomlinson says that bodies that are exposed to the air and to the products of respiration and of ordinary combustion, that are handled or wiped with a cloth, contract more or less a greasy film, which lessens the attraction between the liquid portion of a solution and such surfaces, whilst the attraction between the gasof such solution remains the same. The dust of a room is more or less contaminated with greasy or organic matter, and acts as a nucleus. If such dust be collected on a filter, and washed with a solution of caustic potash, rinsed with water, and dried out of contact with air, it ceases to act as a nucleus. *A nucleus, then, may be defined as a body that has a stronger adhesion for the gas, or the salts, or the vapour of a solution than for the liquid which holds it in solution.* Mr. Tomlinson is of opinion that the phenomena of supersaturated solutions are explained in this manner. That a salt of greater solubility is not formed, and that the state of supersaturation, so far from being one in appearance only, is one of fact, not appearance. The action of nuclei explains the sudden bursts of vapour occasioning the jumping or rebounding of ebullition. If the vessel be chemically clean, or has boiled itself clean, the "*soubresant*" commences. If, instead of an unclean body, we introduce a catharised body into a vessel in which a liquid is boiling with little or no bumping, we may at once bring about such violent bumping as to endanger the safety of the vessel. A little sand steeped in sulphuric acid, and well rinsed with water, or in a weak alkali, is sufficient for this purpose in a flask in which distilled water is boiling. It is said that pointed or rough bodies are better promoters of vaporisation than smooth ones. Make them all alike, chemically clean, and they act alike in impeding rather than promoting the liberation of vapour. It is true that rough bodies are apt to store up between their furrows or teeth that unclean matter which acts so well as a nucleus.

The most remarkable property about charcoal is its untiring activity. No amount of heating or washing in acids or alkalies suffices to catharise it. These processes seem to improve its strong attraction for gas, or vapour in solution. When once in action, it will continue for days and weeks together to give off vapour from the boiling liquid, so that the charcoal does not require to be renewed. A practical hint may be taken from this observation of Mr. Tomlinson.

VALERIANIC ACID AN ANTIDOTE FOR STRYCHNINE.

DR. PALMER of America (*American Journal of Pharmacy*) says, that having occasion to poison four cats, he gave strychnine to two of them on beef. Both died. To the other two he gave it on small tufts of valerian, and without producing the slightest effect. (We think this requires verification.—ED. S.)

FLUORINE IN THE BRAIN.

PROF. HORSFORD (Yale College) states that fluorine is an undoubted constituent of the brain. The reagents, &c., used in determining this point were carefully examined for that element before the experiments. He was induced to investigate this subject from the circumstance that fluorine is so frequently associated with phosphorus.

DETECTION OF SULPHUR AND PHOSPHORUS IN ORGANIC SUBSTANCES.

THE first is accomplished by Dr. Schönn, by heating the substance with potassium or sodium. Hair, feathers, dry skin, and nails, may be at once submitted to ignition with the metal. White of egg emulsion, saliva, and muscle, should first be calcined on a piece of platinum, and the animal charcoal so obtained be ignited with the sodium or potassium. Sulphide of sodium is formed. The test tube, after the ignition, is broken, and its contents are placed in a small quantity of water, rendered acid by a few drops of sulphuric acid. Sulphuretted hydrogen is evolved. If the quantity of sulphur is very small, nitro-prusside of sodium should be used as a test.

The phosphorus is detected by igniting the organic matter previously charred, with magnesium wire, or pulverised magnesium. Phosphide of magnesium is formed, and the fused mass on cooling disengages phosphuretted hydrogen gas on moistening with water.

AVERAGE TEMPERATURE OF THE HUMAN BODY.

THIS subject has been re-investigated, and, according to a communication by Dr. Sydney Ringer, to the Royal Society, it would appear that the average maximum temperature of the day in persons under 25 years of age is 97·7 Fahr.; of those over 40, 98·8 Fahr. There occurs a diurnal variation of the temperature, the highest point of which is maintained between the hours of 9 a.m. and 6 p.m. At about the last-named hour the temperature slowly and continuously falls until between 11 p.m. and 1 a.m. The maximum depression is reached at about 3 a.m. It again rises, and reaches very nearly its highest point by 9 a.m. In persons under 25 the variation amounts to 2·2 Fahr.; in persons between 40 and 50, ·85 of a degree. The variations are independent of the food we eat. By hot water, or vapour bath, the heat of the body could be raised very considerably. The temperature under the tongue noted was between 103° and 104°, a fever temperature. Cold baths lower the surface, but the heat so soon returns that it proves that the cold bath is very little use as a refrigerator.

SUBSTITUTION OF SODIUM FOR PHOSPHORUS IN MATCHES.

THE exclusion of phosphorus from lucifer matches has been looked upon for many years as a desideratum both by the manufacturer and the public, and a rather novel and unlooked-for attempt in this direction has been published by Dr. Fleck, of Dresden. He proposed to use finely divided sodium with some oxidising substance. The match instantly ignites on moistening it with water. He granulates the metallic sodium by shaking it with paraffin melted in a dry flask. The proportions he uses are :—

Sodium	4·65 per cent.
Nitrate of potassium .	61·39 „ „
Sulphide of antimony .	33·96 „ „

Caoutchouc dissolved in petroleum is used for the adhesive paste instead of gum. This plan of making matches has been favourably taken up by some of the German manufacturers.

DECOMPOSITION OF CARBONIC ACID BY GREEN LEAVES.

M. BOUSSINGAULT has, in experimenting upon this subject, made use of a method which is at once elegant and instructive. He introduces a stick of phosphorus into a mixture of carbonic acid and hydrogen, or a mixture of carbonic acid and nitrogen. No white fumes are produced in this case from the slow combustion of the phosphorus ; but if a small green leaf is introduced, white fumes immediately appear from the products of oxygen, resulting from the decomposition of the carbonic acid. This action stops immediately that the leaves are taken out of the light.

◆

THE MORTALITY IN LYING-IN HOSPITALS.

THE meeting of the Dublin Obstetrical Society, adjourned for the purpose of discussing Dr. Evory Kennedy's interesting communication on this subject, took place last Saturday evening, and was attended not only by the great majority of the obstetric physicians of Dublin, but by a large proportion of the profession generally. Before the debate was opened,

Dr. Evory Kennedy said that he desired to be permitted to correct a statement which he had made at the previous meeting. He had found that the mortality in the Vienna Hospital, which in 1838 had been fearfully high, had, according to Professor Faye, greatly diminished since then, and had recently been as low as one per cent. This result Professor Faye had attributed to careful sanitary precautions in respect of the cleanliness of the students in attendance, but Dr. Kennedy did not desire to be understood as adopting this view, but as simply recording the statement.

Dr. George Johnston, Master of the Rotundo Hospital, said that his experience by no means justified the assertion made by Dr. Kennedy, that metria was endemic in lying-in hospitals, or even that when it was epidemic it made its first appearance in these institutions. He considered that common sense would afford a denial to such a statement, for it was incredible that the favourable sanitary conditions of an institution which afforded a cubic space of 1,800 feet to each patient should not afford a safeguard against zymotic disease, as compared with filthy and miasmatous condition of the dwellings of the poor. The circumstances of distress of mind under which many of the patients were admitted were eminently favourable to the production of metria, which should not be, therefore, charged against the institution. The high reputation which the Rotundo Hospital enjoyed would itself cause an apparent increase in the mortality, for it attracted to it all the most dangerous cases, which were afterwards unjustly debited against the hospital administration.

Dr. Atthill, while agreeing with Dr. Kennedy that metria was, under certain circumstances, contagious, sometimes epidemic, and to a great degree preventible, doubted the correctness of the proposition "that any parturient female may generate and absorb herself a poison capable of producing metria." He, moreover, considered it of little importance, for as it is admitted on all sides that it frequently, indeed generally, is the result of the contagion emanating from such diseases as erysipelas, &c., the fact, if admitted, of it being capable of self-generation added nothing to the weight of the argument for a modification of our hospital system. He pointed out the fact proved in the case of the Vienna Lying-in Hospital, that the hands of students engaged in dissections were frequently the cause of the disease, the mortality in that hospital having fallen from 11 per cent. to 1¼ on precautions being adopted for thoroughly cleansing and disinfecting the pupils' hands. Dr. Atthill denied altogether the correctness of the proposition "that the generation and absorption of the contagion of metria was in a direct proportion to the number of females cohabiting together during their puerperal state ;" and to prove its fallacy showed, from the statistics quoted by Dr. Kennedy, that on the eighteen occasions on which over 2,500 patients had been delivered in the Dublin Lying-in Hospital within one year, the mortality had been low, and that even on taking a period of five consecutive years, during which 12,691 women were delivered, the mortality was but 1 in 168—a low mortality, considering the large number of bad cases admitted into it from all parts of the city and country, while now that the number delivered annually was not half as numerous as formerly, the death-rate was much higher. These facts he deemed conclusive, as proving that the development and absorption of the contagion of metria bore no relation whatever to the number of females "collected together during their parturient period." Dr. Atthill concluded by pointing out that the very age in which we lived altered the circumstances of lying-in hospitals, because the necessity which formerly drove ordinary natural cases to seek the shelter of an hospital no longer existed, and thus the class of cases presenting themselves for admission were incomparably more grave than they were some years since.

Dr. Thomas More Madden said that he thought that Dr. Kennedy's estimate of the mortality from puerperal fever would be found to be inaccurate. The proportion had been set down by him for a long period at 1 in 31¾, but Dr. Madden thought the figures would not show this result. Within the last year 1,131 cases were admitted. If Dr. Kennedy's calculation were correct, 37 of these should have died of puerperal fever, but, in point of fact, only 16 so died.

Dr. Kennedy explained that his statement had referred to the general mortality, and not to that from metria alone.

Dr. Kidd laid before the Society the statistics of fifteen years' practice in the Coombe Hospital. 6,573 patients had been delivered at their full term. The total mortality was 1 in 77, of which 1 in 119 was due to puerperal fever, and 1 in 219 to other causes ; 15 cases had been removed, of the result of which nothing was known ; but even assuming them all to have died, the mortality would have been only 1 in 65. Dr. Kidd thought that contagion could not be said to be the greatest cause of puerperal fever, for its variations were so great as to put the uniform operation of any such cause out of the question. The disease varied in its symptoms as much as it did in its frequency, and Dr. Kidd was of opinion that the outbreaks of it were in a much greater degree due to atmospheric peculiarities than to contagion. He was, however, of opinion that the baneful effect of an hospital atmosphere could not be denied. Dr. Kennedy's plan of isolation was not new. It had been tried already in St. Petersburg, and the result was that, while the mortality for the seven years preceding isolation was 1 in 32, that for the seven succeeding years was 1 in 34.

Dr. Mapother concurred with Dr. Kennedy in the deductions from his comparison of town and country hospitals.

Dr. Churchill, President of the College of Physicians, considered that Dr. Kennedy had erred in attaching too great importance to contagion and too little to the epidemic character of the disease. He said his experience by no means bore out the statement that the mortality was altogether insignificant in small hospitals. Dr. Churchill then produced three tables of mortality in various hospitals, and he deduced from them the conclusion that the discrepancy between small and large hospitals was not at all so remarkable as was supposed by Dr. Kennedy.

Dr. John Morgan quoted a fact which appeared to challenge the theories both of contagion and of miasmatous poisoning. In the Lock Hospital there was a small ward containing two beds. In it 74 women had been delivered in five years, under obviously unfavourable conditions of mind and body, and yet only one case of metria had occurred.

After some observations from Dr. Hewitt, and a short reply from Dr. Kennedy, the debate was again adjourned till the next meeting of the Society.

Correspondence.

DUSTBINS AND DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Under this heading I have repeatedly called attention, through the columns of this and other medical journals, to the injurious practice of allowing decaying animal and vegetable matter to be thrown into dustbins; such receptacles should be used exclusively for the purpose for which they are intended—viz., for the cinder ashes, which would cause no injury or annoyance if left for any length of time. I am glad to see that you call attention in to-day's Medical Press and Circular, to the action which has been taken in the matter by Dr. Hearne of Southampton; an example which ought to be followed in other towns; for the complaint is a general one, take Brighton as another instance: the "Ash-heap nuisance" has been a standing subject on the agenda for the consideration of the Town Council, many months, I may say years, and of course the "heap" has been growing and the "nuisance" spreading all the time. Now it is the simplest thing possible to avoid such accumulations; the authorities and householders are alike pusillanimous on the subject; in the first place, it is "bad economy," in every sense of the term, to allow any household refuse to be thrown on the dust-heap, and it could be avoided by means of a very inexpensive contrivance; I suggested the plan in the *Builder* some months ago, it is to have a grating fixed in the form of a lid to the top of the dustbin, this can be temporarily secured by a padlock which is removed for the purpose of emptying the "bin" when necessary; the grating effectually prevents anything but the cinder-ash being deposited in the receptacle.

Then with regard to the contractors for the removal of the dust, they might, if so inclined, enforce a rule which is to be found in most bye-laws relating to the subject; to the effect that the collectors are prohibited from removing any refuse with the ashes; and it is also contrary to the regulations for them to receive fee or gratuity of any kind for the removal of extraneous matter, not coming under the description of dust collection. Considering how potent for mischief the *effluvia* from these "poison nests" prove in the spread of fever, diarrhœa, and other disorders during the summer months, it is quite time that the subject should be vigorously dealt with, and the Royal Sanitary Commission could not better inaugurate its work than by commencing a raid against dust-heaps, and such-like nuisances.

May 6, 1869.
I am Sir,
Yours Obediently,
Sanitas.

NITROUS OXIDE IN DENTAL SURGERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Mr. Dennant in his letter on the Nitrous Oxide states, "that he infers my cases will improve as I advance in investigation," they have not improved. One gentleman lately was very violent, jumping up and striking at every person in the room; on recovering he insisted upon having the tooth extracted without the gas. Another case I can vouch for, a maid servant was so ill from the effects of the gas as to be obliged to relinquish her situation, and has been greatly inconvenienced in consequence. I believe Mr. Dennant will bear me out in asserting that in two cases the cachinations of the patients interfered with the operation.

I admit I am one of the "greatest objectors"—I have seen the gas administered very carelessly on some occasions. I also have seen the gas carefully and successfully given by Mr. Dennant, but from all I have witnessed I can only come to the conclusion that your opinion (which by-the-bye remains unanswered), "that the use of the Nitrous Oxide in private practice is indeed a false possession."

I have formerly had great experience with the laughing-gas, having administered it to *thousands* after a series of lectures; and I am anxious to have your opinion and explanation how it is, that on such occasions, there was no cyanosed appearance, no approximation to smothering or danger. In almost all the cases the inhalation resulted in dancing, immoderate laughing, acting, fighting, &c., &c. I remember one man who came on every occasion of the lecture, and inhaled the gas two or three times during the *same evening*, constantly opened the ball with a very excellent performed sailor's hornpipe. The exhibition I refer to was after lectures, at the Adelphi during the whole of the Lent season. On other occasions there was no surgeon present, I being at that time only a pupil attending hospital lectures, &c., &c. I apologise for this long epistle. I have an interesting case of great mischief resulting from vitiated saliva, if you think it will interest your readers I will, with pleasure, forward it.

Brighton.
Yours truly,
W. S. Whatford, M.R.C.S.

◆

CRIES OF A FŒTUS IN UTERO.

The *Scalpel* states that Dr. Dubreuilh, of Bordeaux, had under his care a girl of sixteen, who, towards the end of gestation, was seized with eclampsia. Chloroform was used, and a very small male child was extracted. The breach of a second child now presented, and, just as the water broke, the persons present heard the cries of the child, as if they issued out of a box, and they continued until the delivery was effected by the feet. The cries were heard at the moment the accoucheur pushed up the breech to seize the feet. Air had probably then penetrated into the uterus, which was not quite filled by the second fœtus, and the latter, having inspired it, began to cry.

POULTICES.

The *Journal des Connaissance Médicales* publishes an article by Dr. Hébert, on a subject which may not be uninteresting to families—viz., cataplasms, those especially which have mustard for their base. The seeds of the black kind, which, in a pulverised state, are used for poultices, owe their properties to a liquid, acrid, and volatile substance, being nothing but essence of mustard. This, however, does not exist ready formed in the seed; it is generated by a kind of fermentation, caused by the action of an albumenoid body, called myrosine, which plays the part of leaven, on a peculiarly fermentescible compound, mysonate of potash, This transformation, which has been called *sinapisic*, can only take place by the intervention of water at a temperature higher than freezing-point, and lower than 75 deg. Centigr., those being the usual conditions requisite for producing fermentation. This is a circumstance which is not commonly taken into account in practice. The generation of the essence of mustard diminishes under a temperature ranging between 50 and 75 deg. Cent., and entirely ceases at the latter. Hence, boiling water, or even such that cannot be borne by the hand, will spoil both the poultice and the sinapised footbath. Again, alcohol, acids, metallic salts, and any other agents, having the power of stopping fermentation, or retarding it, are detrimental. Besides the two principles already mentioned, through whose joint action the essential oil of mustard is produced, the seeds of this plant contains various others, among which there is a fixed and inactive oil, having some of the properties of that of rape-seed, and which may easily be extracted from mustard powder, either by strong pressure, or, better still, by acting upon it by lixivation in a sulphuret of carbon. When this oil is extracted, what remains is much more powerful, and will, moreover, keep indefinitely. Many years ago, M. Robinet attempted to bring this mustard-flour, deprived of its fixed oil, into general use; but prejudice and routine proved too strong for him; and it was not until this powder was gummed to paper, then cut into squares, and sold in elegant tin boxes, that it came into fashion. But what every family should keep in mind is this, that mustard poultices ought not to be made with hot, but with lukewarm water.

WEDNESDAY, MAY 12, 1869.

HOSPITALISM.

THE Science and Art of Medicine owe a deep debt of gratitude to the great "Northern Light," Sir James Simpson, firstly, and above all other reasons, for his great gift to the human race in his discovery of the anæsthetic properties of chloroform. Had he, indeed, lived in the days of belief in a plurality of deities, we should no doubt have thought it our duty to raise him to one of the thrones of Olympus. Living, however, in days which are "destitute of faith, though terrified at scepticism," we have done nothing of the kind; and, indeed, as far as we are aware, neither Sir J. Y. Simpson nor, more recently, Dr. Benjamin Richardson have received anything save unsubstantial honours for two of the greatest discoveries which the human race has ever been blessed with. Not contented, however, with the achievements of his early life, and the fame which so justly belongs to him for his ingenious and manifold discoveries in the obstetric department of medicine, the illustrious inventor of chloroform is now doing immense service to his kind by exposing the dangers which arise to patients, especially to those suffering from open wounds, from residence in large, and, above all, in ancient and long inhabited hospitals. We have long secretly entertained the opinion that large hospitals are great evils. When studying in a prolonged course of "walking" our own and foreign hospitals, indeed, it has so frequently been our lot to witness several cases of pyæmia occurring at once in the same hospital after amputations, that we had secretly registered a vow that we should never allow any person we entertained any great affection for to enter any large hospital to be operated upon, even by a Nélaton or a Fergusson, unless the operation was one involving no risk at all of purulent or septic poisoning. On one occasion, indeed, we remember to have heard M. Nélaton exclaim, at the Hôpital des Cliniques at Paris, that he would operate no more that season, since all his amputation cases, for several months previously, had died from diseases of hospitalism. And yet, with such facts well known to many of us, if not to all, we see a magnificent pile of buildings arising opposite the Houses of Parliament, with palatial wards, destined, no doubt, ere long to repeat the same tale that has to be told for Guy's and St. Bartholomew's, and other large hospitals—viz, that a patient about to have an amputation of the thigh stands three times the chance (according to Sir J. Simpson) of succumbing after it than if he had been operated on in a country cottage.

We hear that the Chancellor of the Exchequer is anxious to save money on the construction and site of the Law Courts. Could he not buy up the new St. Thomas's Hospital, and let the funds of that great charity be employed in a manner which is more in accordance with the science of the day, in erecting a number of cottage hospitals, with a central administration, where patients would "live and not die," as Miss Nightingale expresses it, in her admirable work, read, we fear, by too few among us, "Notes upon Hospitals?" There we find, as proved over and over again by the accomplished lady writer, that, just in proportion to the size of a hospital seems to be the mortality after operations; and, although this admirable remark has been slighted because it came from the mouth of one of the gentler sex, it can no longer be ignored when proclaimed so loudly and energetically by the greatest ornament, perhaps, of the medical profession in this country. It appears, according to the statistics furnished by that distinguished surgeon, Mr. Holmes Coote, that in St. Bartholomew's Hospital 2,131 registered operations have been performed during the years 1863-7, with 277 deaths, equal to a percentage of 12·9, or about 1 in 7½; and this is, he adds, about the same as Sir J. Y. Simpson's death-rate after "limb amputations in rural practice, which he puts at the favourable figure of 1 in 9." To this, Sir J. Simpson replies (*British Medical Journal*, May 1st, 1869) that, "among the 2,131 registered operations at St. Bartholomew's Hospital are entered 185 amputations of the fingers and toes, with 3 deaths; 216 cases of excision of benign tumours, with 5 deaths; 71 cases of hydrocele and hæmatocele, with 1; 63 cases of fistula, with 2 deaths; 30 cases of circumcision, with no deaths; 105 cases of tenotomy, with no deaths; 16 cases of ligature of piles and 22 of nævi, with no deaths; 14 cases of operation for ectropion and 18 of extraction of the lens for cataract, with no deaths, &c." Hence, of course, Mr. Coote's argument is so far without value. Dr. Southey and Mr. Mallet, however, it appears, have drawn up a table of 214 amputations of the thigh, leg, arm, and forearm, occurring in St. Bartholomew's Hospital, of which 81 died—*i. e.*, 1 in 2·6 operations led to death. Now, on the contrary, it appears that of 2,098 similar operations collected by Simpson from private rural practice, the mortality was only 1 in 9·2 of those operated on—that is, more than three times as many died in St. Bartholomew's than would have died had they had themselves operated upon even by practitioners of far smaller experience, because the pure air of the country was about them, even in cottages and without any of the splendid surroundings of the palatial hospital in Smithfield, or the careful and experienced nursing there.

What need of more? We say the case has been heard, and the jury can only pronounce the doom of the large hospital system. It has been asserted that large hospitals are cheaper than small ones. This, too, it appears, is a mistake. The patients get well far faster in a small hospital than in a large one, and are off and about their business whilst the poor patient in the large hospital is lingering on amid scenes of sorrow and woe. We shall never forget the case of a friend having been taken with fever in a large foreign capital, and awakening to consciousness in a large ward of an immense hospital, next bed to him being a poor fellow who had just died of some contagious disease. The feeling of despondency experienced by this patient in that situation, and communicated to us, has made us feel how injurious the effect of large collections of the sick and dying must ever prove in cases where the poor patient is sensitive and suffering from a complaint, such as amputation of an extremity, when hope is one of the most blessed therapeutic agents we can employ to arouse the vitality of the sick.

Again, what horrors have we not witnessed in these large hospitals for consumption, which the mistaken philanthropy of our day has constructed. A poor fellow, a poet, we remember struck with that awful disease, was sent down to a consumption hospital on the south coast. He slept but one night in that scene of human decay and then fled, horror struck at the pallid looks and sepulchral coughs which on every side met his ears. And yet we see large hospitals, such as Brompton and Victoria Park, flourishing, although it is confessed on all sides that they are utterly useless in a therapeutic point of view, whilst, hygienically, Brompton Hospital could not be placed in a worse position. Henceforward it is to be hoped that hospitals where operations are to take place may be made to contain not more than five or six patients in each cottage. Acute diseases, perhaps, such as pneumonia and fever, are not so much injured by a residence in large hospitals; but even in the case of fever, we have long ago wondered what reason could be alleged for the practice of collecting a heap of cases of typhus and typhoid fever together in a large ward. As Sir J. Y. Simpson remarks, too, it is probable that large hospitals are far more expensive than small ones, and now-a-days, when railways have made even London distances almost disappear, there can be no excuse for ever again raising such piles of buildings as St. Bartholomew's or Guy's or St. Thomas's Hospitals. Hospitals for consumption should contain not more, we think, than twelve, or at most twenty beds. More than this becomes a scene of suffering and despair.

◆

MORTALITY OF THE PAST QUARTER.

Our readers will not need to be reminded how frequently, during the mild winter, we called attention to the favourable condition of the public health. Then came the sudden severe weather, which made Easter so wintry, impressed Englishmen once more with the fickleness of their early springs, and considerably raised the death-rate. It is not surprising that so sudden a fall in the temperature should seriously affect the mortality, for it is now an axiom that such a decrease is thus injurious, and that its pernicious influence is most felt by the very young and the very old. So thoroughly did the cold do its work that it actually influenced the figures of the Registrar-General so far as to raise the mortality of the first quarter of 1869 above that of 1868. Even now, however, it is rather below the average of the last ten years, so that, on the whole, the quarter has been a very healthy one. In 1868 the mean temperature of the quarter was not very different from that of 1869—one decimal point only—41·3 and 41·4 expressing the facts. Yet the deaths differed by no less than 14,000. This is the result of the variations. In January and February there was a daily excess of 5¼° Fahrenheit, while the temperature of March was 4° Fahrenheit below the average. To this we attribute the apparent unhealthiness of the last quarter, which illustrates thus aptly the relations between weather and disease. The quarterly return of the Registrar-General to the end of March has just been issued. It points out that the epidemic of scarlet fever prevailed, and alludes to the weather, which, in the beginning of January, was warm, but then succeeded by about a week of cold, which week considerably augmented the deaths from bronchitis, &c. He then speaks of the whole of March as cold. We extract the following details:—

> The mortality of the quarter, which was at the rate of 24 84 per 1,000 per annum, is slightly below the average of the season of the last ten years (25·36) and compares favourably with the rate observed in the three years 1864-6, but exhibits an increase over the winter of 1868, when the mortality was at the exceptionally low rate of 22·34 per 1,000. The Registrar-General observes that the winter just gone affords another example of the effect of vicissitude of temperature on the health of the people, and warns those who are very susceptible to such variations, to endeavour in their manner of life to counteract in some measure the severity of the climatic changes experienced in an English winter. For the edification and guidance of the community, he shows that the period of life when the greatest susceptibility to a fatal attack of bronchitis exists, is after sixty-five; but at the age of forty-five and under fifty-five, the increase is remarkable; as also is the high rate of mortality in infancy. The average annual death rate from bronchitis among males is 4·42 per 1,000 living at the age under five years; at the ages of five and under forty-five the mortality is comparatively inconsiderable; at forty-five-fifty-five it is 1·51 per 1,000; at fifty-five-sixty-five it is 8·79; and continues to increase as age advances—viz., 3·7 at sixty-five-seventy-five; 16·14 at seventy-five-eighty-five; 22·76 at eighty-five-ninty-five; and 23·57 at the age of ninty-five and upwards. The prevalence in many places of scarlet fever prevents the quarter being classed as healthy; indeed, if the prevalence or non-prevalence of zymotic elements in the metropolis may be taken as an indication that the same condition exists over the whole of England, then the 648 deaths registered in London from scarlatina during the first quarter of the present year, against 339 and 368 in the winter quarters of 1867-8, imply that the country was visited very severely by this epidemic last winter. One of the most important features of the return consists in the comparative mortality of the large towns of the kingdom a selection of 14 great cities, arranged in order of their respective annual death rates for the quarter, shows the following results:—Birmingham, with a population in 1869 of 360,846, shows a death rate of 20·70 in every 1,000 persons; London, with 3,170,754, 25.43; Hull with 162,682, shows 26·30; Bristol, with 769,423, shows 26·60; Bradford with 138,522, shows 26·86; Leeds, with 253'110, shows 57·54; Salford, with 119,350, shows 27·78; Dublin, with 320,762, 59·07; Sheffield, with 239,752, shows, 29·35; Liverpool with 509,052, shows 29·61; Newcastle-upon-Tyne, with 130,503, shows, 30·42; Manchester with 370,892, shows 30·97; Edinburgh, with 178,002, shows 33·01; and Glasgow, with 458,937 shows 40·70. So Birmingham, among the west midland counties, and London have enjoyed the greatest amount of health, and Edinburgh and Glasgow the least.

◆

SCOTLAND.

Royal Society.—At a late meeting of the Royal Society of Edinburgh—Professor Christison, vice-president in the chair, Dr. W. Rutherford read a paper on "The influence of the vagus on the vascular system." Mr. Robert S. Wyld, another on "Sense-perception as a perception of power," was next read. A paper on "The affinities and classification of the Nemerteans," by Dr. W. Carmichael M'Intosh. The concluding paper was by Professor Maclagan and Dr. Arthur Gamgee, on "The alkaloids contained in the wood of the Beebeern or green-heart tree (Nectandra Rodiœi, Schomb)," and read by Dr. Gamgee.

Opening of the Edinburgh University Summer Session.—The summer session in the University opened on Wednesday, the 3rd inst., and at all the classes there was a good attendance of students. The first lecture, was delivered by Professor Balfour, in the lecturer hall at the

Royal Botanic Garden. In the course of his lecture Dr. Balfour reviewed Professor Huxley's recent theory regarding protoplasm, and warned the students against being led away by such dangerous speculations, unsupported as they are by fact or evidence. It was impossible that this protoplasm could form the basis of physicial life, seeing that it was always the result of previous cell-life. The chemist could not produce it so that it would exhibit vital phenomenon and impart life to new structures. The life which it possesses must be given to it from without, and that life can only come from Him who is the source of all life, through the agency of previously existing living organisms. He thought Professor Huxley had miserably failed in throwing the slightest ray of light on the unknown secrets of life. In conclusion, the Professor dwelt on the bearings which the study of botany had on other branches of science, and encouraged the students to compete for the degrees, scholarships, and bursaries of the University.

THE President of the Royal College of Physicians of Edinburgh has appointed Dr. A. Mitchell, to deliver the lectures on Mental Diseases, for the next three years. The office was held by the late Dr. Seller, under the will of Sir A. Morrison.

◆

GERMANY.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, March 28.

BESIDES the schools I have described, there is in Austria and throughout Germany (principally northern Germany) a new one, formed by joining two opposites, the old Allopathic and Homœopathic school. It is like the proposed union of the English Church and the old Greek Church. It may be called the empirical school. It was founded by Rademacher at Goch, a little town on the frontier of Germany and Holland. His experiences are deposited in a large work of two volumes, with the title, "Defence of the Old Scientific Experience; Defence of the Principles and Experiences of Theophrastus Paracelsus."

These empirics employ only specifics for systems and organs, but not in homœopathic doses. Rademacher's work and his disciples are more despised by the modern physiological school than the homœopaths themselves. These empirics, on the contrary, despise the physiological school, and reject all theory. They appeal only to clinical experience. They accept clinical facts observed by homœopaths, but reject the dogma "similibus."

Rademacher is the founder of the school in the sense that he has extolled empiricism, which always existed, and reduced it to a system. His remedies are divided into—

I.—UNIVERSAL REMEDIES.

II.—SPECIAL REMEDIES.

I.

Universal Remedies.

1. Soda and its preparations: Liquor natri nitrici; soda nitrica; specific in some cases of dysentery. Tinctura ferri acetici. 2. Iron and its preparations: Liquor ferri muriatici oxydat.; liquor stypticus; ferrum carbonicum. The mineral acids are relations to the preparations of iron. 3. Cuprum: tinct. cupri acetici.

II.

Special Remedies.

A For the Organs of the Head.

a For the Brain.

1, Tobacco; 2, zinc; 3, stramonium; 4, argenti chlor.; 5, opium; 6, hyoscyamus; 7, cannabis indica; 8, belladonna; 9, camphora; 10, coffee; 11, argent. nitri; 12, green tea.

b Against Coryza.

Camphor (as a snuff or vapour).

b Against Epistaxis.

1, Ferrum muriat. oxyd. (if it is local); 2, zinc.

c Against Aphthæ.

1, Borax; 2, balsam vitæ Hoffm., with syrup of oranges.

d Against Parotitis.

Iodine.

e Specific for the Bronchial Tubes.

1, Sulphur auratum antimonii; 2, mercury.

f For the Lungs.

1, Salmiak; 2, sulphur aurat. antim.; 3, extract of tobacco.

g For the Heart.

Digitalis.

h For the Œsophagus.

Boracic acid; magnesia.

i General Remedies for the Abdomen.

1, Seeds of thistle of Maria (semina cardui Mariæ); 2, terebinthina c. æther sulphur.

k Special Remedies for (the organs of) the Abdomen.

α For the Liver.

1, Quassia; 2, chelidonium; 3, calx chlorata, single or in combination with chelidon; 4, nux vomica.

β For the Spleen.

1, Carbo vegetabilis; 2, scilla marit.; 3, aqua glandium; 4, baccæ juniperi; 5, oleum succini; 6, conium maculatum; 7, magnesia tartarica; 8, cicuta; 9, acidum pyrolignosum.

γ Against the Pancreas.

Iodine.

δ Against the Plexus Cœliacus.

Aqua amygd. amararum.

ε Specifics for the Stomach.

1. For neutralisation of the acid:—Natrum carbonic, nat. bicarb., magnesia carb., ammon. carbon, lapides cancrorum.
2. Bismuthum nitricum.
3. Kali aceticum.
4. Natrum aceticum.
5. Iodine.
6. Calx chlorinica.

ζ Specific for the Intestines.

1. Oleum papaveris, with arabic gum and water.
2. Iodine.
3. Tinct. nucis vomicæ, with tinct. assafœtid.
4. Zincum aceticum.
5. Catechu and salmak.
6. Aromata, nux moschata, flores macis, caryophyll.

η Purgantia.

1. Clyster of salt water.
2. Colocynthis.
3. Purgative salts.

κ Specific against Worms.

1, Cuprum; 2, aloes; 3, oil; 4, senna.

λ Specific for the System, venae portarum.

1, Sulphur; 2, leeches for the rectum.

μ Specific for the Urinary Organs.

1, Magnesia; 2, aqua calcis; 3, potass carb., soda carb., ammon. carbon.; 4, tart. boraxatus; 5, colocynthis; 6, aqua opii; 7, coccinella; 8, solidago Virgaurea; 9, fomenta tepida; 10, magnesia usta cum coccinella; 11, tinctura capsellæ bursæ pastoris.

ν Specific for the Bladder.

1, Fungi, or glomeres cynosbati; 2 liquor ammonii sulphurati.

ο Specific for the Womb.

1, Tinct. nucis vom.; 2, castoreum; 3, borax.

ρ Specific against Intermittent Fever.

Combination of quinoidin and quina.

σ Specific against Furuncula.

Calx chlorinata.

τ Specific for Measles.

1, Arnica; 2, folia fraxini excelsioris; 3, sal Glauberi; 4, iodine; 5, nux vomica; 6, calx chlorinica.

υ Specific against Chronic Exanthems.

1, Sassafras; 2, quassia; 3, trifol. fibrin.

III.

External Remedies.

1, Natrum cum adipe; 2, aqua calcis; 3, magnesia; 4, solutio sublimati; 5, pulvis sulphuris; 6, mastich; 7, folia rosæ; [8, aqua amygd. amara; 9, mer. præcip. albus; 10, plumb. acet.; 11, zincum aceticum; 12, solutio salis culinaris.

The above completes my sketch of the divisions or schools of Austria. I should not have given so much space to this which is in such bad odour and not much known, I think, out of Germany, but there is scarcely a village throughout Austria where you will not meet a professed disciple of this Rademacher. These empirics exercise, therefore, a great influence, and it is impossible to understand our social condition unless you are acquainted with their existence and numbers.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, APRIL 24, 1868.

I LEAVE the rest of the schools and professors for a future letter, lest you get tired of such details, and propose to fill up a column with a curious practical fact or two, which I have been asked to repeat more widely when I have named them to some intimate friends. It will not be needful to give opinions upon all the facts I relate. When I vouch for them personally they have come within my personal experience either in hospitals or in my private practice. When I know only by hearsay I shall say so explicitly.

First, then, the eucalyptus is, I think, a very valuable febrifuge. It may sometimes take the place of quinine.

Eucalyptus globulus against intermittent fever and consumption was first employed in Spain. From the leaves they make an infusion, which is aromatic in taste and smell, like the leaves from which I send you some specimens. This tree grows in Australia, where it attains a height of 300 to 400 feet, and proportional in size; it is also very frequently cultivated in Southern Europe, where it becomes 100 feet high. The development of this tree is so rapid that a specimen of it, exhibited at Paris, has grown up to the height of fourteen feet in one year. The young plants resemble the euphorbia lathyrus, whilst the whole plant belongs to the botanical family of myrtaceis. In Australia, even in marshy regions, intermittent fevers are very rare everywhere those trees grow and its relations. Also, the tincture prepared from the juice of the fresh leaves can be employed.

Spontaneous healing of a cataract.—Twenty years ago I paid a visit to a priest in one of the villages near Sadowa, in Bohemia. After having examined the antiquities of the church, the parson, a little, stout, well looking man, of about fifty years, wearing spectacles, told me that he suffered blindness of the right eye for fifteen years, and asked me if he should have an operation for the cataract performed. Then I examined more accurately the eye, letting him cover the good eye by a handkerchief, whilst at the same moment I held my left hand before his blind eye, and moved it a little up and down in order to know the contractility of the iris, which I found all right. I told him he should not submit to the operation as long as the other eye was strong enough. With this advice I left him. Three weeks afterwards he came to me, his face bright with pleasure and contentment, telling me that since I had visited him he could see with the right eye, and he recounted me the following details:—

"When you went away I repeated the method of movement of your left hand before my eye. As I thought that it was a kind of mesmerism, I wished to imitate the movement, and covered the good eye with my handkerchief; but before I had time to begin the movement I cried out for astonishment, 'I can see!—I can see the first time after fifteen years.' And now I tried to make the same movement before the eye more than fifty times a day. The next morning all the parish was astonished to see me reading the mass without spectacles, and I told the people that a miracle gave me sight. I continued to make movements till to-day, remarking every day a little improvement. I can now read large characters, and distinguish every person in the street."

I replied to him that it is not possible that the little movement of my hand made him see again; there must be another important circumstance which he forgot to tell me, and I asked that he should relate the history of the last fifteen years.

"About half a year ago I caught, whilst perspiring, a violent cold and an intense inflammation of both eyes, so that I could not see, and bloody pieces came out from the eyelids. I did not employ other remedies than cold water exteriorly. After three weeks I got as well again as I was before this inflammation."

When I heard this account I was convinced that the cataract was melted by the inflammation (as the old snow is melted by the fresh one), and that he could see with the right eye after the inflammation without knowing it, only since the moment when he covered the left eye he became aware that he could see; and he attributed this astonishing change to the movement of my hand. Instead of preferring to continue to appear as an enchanter and worker of miracles to him, as I then did, I explained to him all the process; and that by moving the iris he accelerated the action which appeared to my eyes really as water-fall from the posterior chamber into the anterior, and changing form and volume at every movement of the iris. As I heard afterwards, this cataract disappeared entirely by degrees, and the curate could see very well with such spectacles as are used by those who have had a cataract extracted.

THE WINTER AT NICE.

(FROM OUR OWN CORRESPONDENT.)

NICE, May 4th.

SINCE I wrote about the lady supposed to have lost her life by carelessly bathing, circumstances have come to light which render it probable she may still be on the land of the living. Only a small portion of her garments were found on the shore, and the sea should have returned the corpse if it had taken the life. Scandal says the bathing was but a *ruse*.

We have now delightful weather, only the sun is so exceedingly powerful that one must stay in the house the middle part of the day. The gardens are inconceivably beautiful. The cold winds stayed a long time with us. As some people have been vexed with me for telling you about them, and some deny my statements, I think the only mode is to give you the meteorological record for March, the month about which I complained. I therefore give you below a true copy of the statistics from the registers of the observatory in the grounds of the Military Hospital, and for the correctness of which the reputation of Dr. Cabroll, principal medical officer, as a meteorologist suffices. You will see how capricious the weather was in that month, though I have heard it was just the same in many other health-resorts. The letter of Dr. Hawkins in your paper, about the drainage here, may do some good. It irritates some of the proprietors, and I hope it will induce the Mayor to take this vital question up. The doctors, some of them, know how things are, but fear lest publicity may prevent patients coming next year.

TABLE OF THE WEATHER AT NICE.

Month of March.

	Thermometer.			
	Maxim. Deg. C.	Minim. Deg.	Wind's Direction.	Force.
1	18·3	—·4	N W S W	Great wind.
2	20·4	5·3	N W S W	Great wind.
3	17·4	1·4	N E S E	Soft.
4	14·7	—·8	N E N W	Fresh.
5	13·4	—·1	N E N W	Fresh.

TABLE OF THE WEATHER AT NICE—*continued.*

6	13·7	—·4	N E	Very soft.
7	15·4	2·3	N E N W	Idem.
8	12·3	4·1	N W N E	Great.
9	11·2	4·1	N W N E	Idem.

31	9·7	2·3	N E S E	Fresh.

◆

Notes on Current Topics.

Poor-Law Doctors and their Remuneration in London.

THE *Poor-Law Chronicle* of April 21st, publishes a most instructive analysis of the return recently presented to the House of Commons on the motion of Mr. Torrens. The paper shows the number of medical officers in each union and parish in the metropolis, with the total amount of remuneration, inclusive of salaries, fees, &c., paid to them, stating whether all or any of the medicines are supplied by the guardians, ... together with the total number of sick poor attended during the year ended 29th of September, 1868.

It appears that there are 39 unions or single parishes in the metropolis, including the new union of Woolwich which has at present no workhouse.

The number of in-door sick poor attended in the year ended September 29, 1868, by the 55 workhouse medical officers was 79,375, or an average of 1,443 to each. The 159 district medical officers attended 268,135 sick poor during the same period—average 1,686.

The 214 medical officers received on an average £133 13s. 9d. per annum, or 1s. 8½d. for each sick persons attended.

With respect to the supply of medicines, it is difficult to obtain reliable information. The drugs supplied by the guardians of Marylebone cost £211 10s. 8d.—a sum which divided by the number of medical officers, would give to each an allowance of £26 8s. 10d.; but the supply it turns out, was confined to the workhouse, whose chief officer is so handsomely paid; and the district medical officers were burdened with the charge of providing all the medicines for their numerous patients. The same practice of finding drugs for the in-door poor only prevails in many unions.

In a preceding issue the *Poor-Law Chronicle* published a comparison of the medical arrangements in Bethnal Green and Poplar, both unions being in the east district. This return carries the comparison a little further. The nine medical officers of Bethnal green are paid £1,020 (£113 6s. 8d. each). Their more fortunate brethren at Poplar, six in number, received £1,656 6s. 11d. (£276 1s. 2d. each); all the medicines prescribed by them, moreover, being found and dispensed at a cost to the guardians of £858 15s. 2d., or at the rate of £143 2s. 6d. for each officer —£30 18s. 1d. more than the total average remuneration of the Bethnal Green officers, all of whom, excepting those of the workhouse, provide and dispense all the medicines required by the sick of that very poor parish!

We find it impossible to do justice to this valuable analysis this week, but we shall hope to return to the subject.

Hanging no Punishment.

THE American Constitution, so perfect in the eyes of progressive Liberalism, has not yet accepted the abolition of capital punishment, but it has shown us the way to a half measure which might be acceptable just now as a sort of compromise between hanging and reprieve. A punishment which would combine all the moral effect on evil doers, and all the deterrent horrors of death to the culprit himself, and would yet give a chance of living a repentant life afterwards, would be a real acquisition to those interested in the repression of crime.

The *Philadelphia Free Press* furnishes us with a new phase of retributive justice, which from the circumstantiality and publicity of the narrative is, we are bound to presume, countenanced by the American Government. The *Free Press* records how a murderer was recently executed, and describes the subsequent proceedings.

Arrangements were made by the friends of the condemned to have an effort made to resuscitate the body. Accordingly a committee, appointed for the purpose, were in waiting at the prison at the time of the execution, and the body, wrapped in blankets, was brought to the university. The drop was four feet; the cord round the neck was a small one. He hung by the neck thirty minutes. and there were signs of life only four minutes after the drop. Ten minutes after being cut down he was placed upon the table in the amphitheatre, the time elapsing from the execution being forty-four minutes. Six ounces of whisky were injected into the bowels, and one gallon of pure oxygen gas was forced into the lungs, and a powerful galvanic battery applied to the medulla oblongata and the pit of the stomach. At the same time the tongue was withdrawn from the mouth, and the body turned from side to side, after the method of Marshall Hall, for artificial respiration. In four or five minutes a marked change occurred in the countenance; the chest gradually expanded, the eyes opened, one arm was drawn up, and, by means of a stethoscope, contractions and dilations of the heart were distinctly heard. So evident were the signs of life that his friends exulted over the fact that he really lived. Another gallon of oxygen was introduced into the lungs, and the battery was charged, so that the current passed the entire length of the spine, and the artificial respiration continued. For a few moments the signs of life increased, but in a short time disappeared. Nitrous oxide gas was injected into the lungs by an artificial opening into the trachea, made by Professor Duffee, but all to no purpose, and at the expiration of one hour and twenty-five minutes the experiments ceased, and the body was handed over to the friends.

What happiness for Mr. Bruce and our future Home Secretaries an assimilation to American custom in this matter would be, and how consonant with the present tone of the House of Commons would be a proceeding so scientific in detail and so convenient in practice.

Insanity in Edinburgh.

The annual statement of the Edinburgh Asylum for the Insane has just appeared, and it informs us of the result of the years of working of the Institution.

Of the removals, 121 had recovered, the recoveries being in the ratio of 43·4 to the admissions. This is the largest number of recoveries for any one year that the records of the asylum can show, and, with one or two exceptions, the largest percentage of recoveries.

The number of patients admitted into the asylum since its foundation now amounts to 7,144, of whom 2,740 have been discharged recovered, being in the ratio of 38·5 per cent. to the admissions, or of 42·65 per cent., if the number remaining under treatment is deducted.

The percentage of recoveries of all the large asylums of England, as collated by Dr. Conolly, appears to be about twenty-one per cent. to the admissions, so that our percentage of 43·4 may be regarded as exceedingly favourable, especially when the nature of the cases admitted is considered, many of them being in a most hopeless condition.

The same remarks apply to the mortality, which has been lower than it was for many years preceding the improvement of our dietary, and may be regarded as very moderate, if the number of cases that were brought to the asylum in a dying condition were deducted.

The Royal Irish Academy and the Scientific Societies of Dublin.

The proposition, analogous to that which has emanated from the Royal Medical and Chirurgical Society of London, to which we alluded in our last, has been accepted by the Natural History Society We append the detailed proposal which is issued under the title of

Draft Suggestions *submitted by the Committee of Science of the Council of the Royal Irish Academy at a Conference of Representatives of the Councils of the other Scientific Societies of Dublin, held in the Academy House on the 22nd of April* 1869, *for the purpose of Promoting the Advancement of Science, by the amalgamation of all the existing Dublin Societies with the Academy.*

I. That the business of the Academy shall be conducted by five sections :—

1. Mathematical and Physical.
2. Chemical.
3. Geological.
4. Biological; that is, Natural History as usually understood, and Physiology and Comparative Anatomy.
5. Archæology, History, and Philology.

II. That the Council of the Academy shall be formed of twelve representatives of Science, and nine of Archæology and Philology.

III. That each Scientific Section shall have a committee, consisting of a President, Vice-President, Secretary, and Committee, elected annually by the Academy at large from a list prepared by the Committee of the Section. That the President so elected shall be made a Member of Council, and be nominated by the President of the Academy a Vice-President of the Academy. By the Charter of the Academy there can be only four Vice-Presidents, In order to meet the difficulty of having only four Vice-Presidents and five Sections, it has been suggested that the President of the Academy for the time being should act as President of one of the sections, he selecting the one with which he may happen to be most connected, or which should be most congenial to his tastes.

IV. That each section may have its own night of meeting, but that any two or more sections may arrange the meetings for the same night.

V. That there shall be at least two General Meetings of the Academy at large, on the nights provided for in the Charter, at one of which the elections for the Members of Council, the officers of the Academy at large, and the officers and committees of Sections shall take place. And it is recommended that these General Meetings should be made as interesting as possible by the exhibition of specimens, the delivery of a lecture, &c.

VI. That with a view of rendering the meetings of the sections as interesting as possible, steps be taken to have tea provided at each meeting.

VII. That the proceedings of the academy be divided into two series—one for Science, and the other for Archaeology, History, Philology, &c. The complete separation here recommended to be effected after the completion of Vol. X., now in course of publication.

VIII. That the officers and Committee of each Section shall determine what papers, reports, &c., should be read or business transacted at its meetings, and superintend the publication of their proceedings. But that there should be, as now, a Committee of Publication of the General Council, to superintend all the publications of the Academy, upon which each section should be adequately represented. The Papers recommended for the Transactions to be voted for in full Council as at present.

IX. That with a view of encouraging the reading of papers before the sections of the Academy, the author of a paper be at liberty to publish it, where and when he chooses, provided he appends a note stating that it had been read to the academy.

X. That, as now, the committees of the Council having the management of the funds, the buildings, &c., namely, the Economy Committee, &c., be appointed by the Council, and that all disbursements, &c., be made through the Treasurer of the Academy.

XI. That all the members of the Societies proposing to merge into the Academy be co-opted by the Academy without entrance fee, and in such a way as may fulfil the provisions of the Charter.

It was suggested at the Conference that Life Members of Societies about to join the Academy should be considered as Life Members of the Academy during whatever period may be determined upon for making the experiment, on condition of the interest of so much of the stock of the Society representing their life compositions being paid into the Academy.

It was also suggested that if a Society permanently joined the Academy, the whole of their funded stock should either be added to the stock of the Academy, or kept as a separate fund for the promotion of the special branch of Science of the original Society as may be afterwards determined upon. In either case, the Life Members of the Society to be considered as Life Members of the Academy.

It was also suggested, that the library of any Society joining should be placed in the library of the Academy, but it should not become the permanent property of the Academy until the Society has finally merged in the Academy.

The Townshend Reforms.

We do not number amongst our personal friends the Marquis Townshend, nor do we happen to know any one who has any faith in that nobleman's proposals for improving society. He evidently, however, has faith in himself, for he has a neat lot of 11 bills before the House of Lords. Some of these do not concern us very seriously, for instance, that relating to the birching of school-boys, as the marquis does not propose to create medical inspectors to see that his regulations for birching are duly complied with, and the inspection of "baby farming" is to be carried out by the relieving officer. But there is something that concerns the profession. Our aristocratic social reformer wants to compel vaccinators to obtain a certificate of the source of the lymph they employ. Now, most noble Marquis, what about the pay? Vaccinators already have to fill up an unreasonable number of certificates, and doctors are constantly doing an inconceivable amount of work gratuitously, to the injury of themselves as individuals, and as an order, as well as to a thankless public. We have no objection at all to any one engaging in what he thinks to be social reforms, but we do protest against his doing so at other people's expense. Any one who wants certificates in matters medical, can have them by paying for them. Would that no one could get them without.

Newcastle-upon-Tyne Asylum.

The report of the medical superintendent, Dr. H. S. Grainger, shows considerable pressure on the resources of the institution, which, however, will soon be relieved by the new buildings, one of the wings of which will be occupied at once. The mortality of the year was above the average, being 12 males and 5 females, equal to a per centage of 11·9, Disease of the brain was the chief cause of death. One suicide occurred, although great precautions were taken to prevent the catastrophe.

A good deal of work, including the making up of the whole of the clothing was done by the patients, and we are glad to note that amusements were provided in the the form of weekly concerts, dances, or dramatic readings and representations.

We may add that the library is rather short, and that presents of periodicals or books would be acceptable. We hope the people of the borough of Newcastle will take the hint.

The Health of Dublin.

In the Dublin Registration District, the births *registered* during the week ending May 1st, amounted to 181. The average number in the corresponding week of the years 1864 to '68 inclusive, was 182. The deaths registered were 144. The average number in the corresponding week of the previous five years was 164. Seven deaths from scarlet fever were registered: of these, 1 occurred on the 29th of March, and another on the 1st of April. One death was ascribed to typhus, and 2 to typhoid or enteric fever. A male, aged 15 years, and a policeman aged 23 years, died of "cerebro-spinal meningitis." Erysipelas caused 3 deaths, diphtheria 2, and croup 1. Nine children died from convulsions. Bronchitis proved fatal in 24 instances, and pneumonia or inflammation of the lungs in 4. Seven deaths resulted from heart disease, and 1 from aneurism. Four deaths were attributed to liver disease. Phthisis or pulmonary consumption was the cause of 15 deaths, and mesenteric disease of 3.

"Royal Society of Medicine."

The discussion at the "Medico-Chi" took place as announced, and a very desultory and unsatisfactory one it proved, ending in a resolution that the proposed "academy" should be called society. The meeting was then adjourned for a fortnight. Some gentlemen had such vivid recollections of the word academy in the sense of a school that they could not be persuaded to entertain the project under that name, so eventually it was agreed that the old and respectable "Medico-Chi" should carry out its proposed affiliation of several other societies under the name of the "Royal Society of Medicine." What a wonderful advance! Need medicine despair when its leading metropolitan professors spend a whole evening in debating such a question? Surely great things must be in store when the great debate of the year is but a new reading of "what's in a name?"

We have already given full information as to the scheme of amalgamation, and should be glad to see any plan accepted which would put a stop to the waste of power that exists in the two great division of the societies. But we do feel that this plan is not sufficiently broad. It only proposes to take in some of the societies by way of bringing new blood to the "Medico-Chi," and at the same time replenishing its coffers. A little greater liberality in the matter of entrance fees and subscriptions would apparently accomplish all that the majority of the "Medico-Chi" care for.

The Medical Council.

This body will soon meet, and the British Medical Association Committee is making another effort to push its plan of what it calls the *direct* representation of the profession in contradistinction from that which it incorrectly describes as the *indirect* method of Dr. P. James, and which latter now has the support of the majority of reformers. Our contemporary, the *Lancet*, has also now pronounced in favour of the latter scheme, which it speaks of as the "collegiate one" with an amusing fear of allowing its readers to know the name of its originator. Of this we may be quite certain. What are sometimes described as corporate interests will rebel against any plan whatever, and yet nothing would please the profession more than such an enlargement of the franchise of all the corporate bodies as should give every individual member of them a voice in their management. The *Medical Mirror* has lately taken the opportunity of stating that the plan of Dr. Prosser James is too complete, inasmuch as it would reform at one stroke not only the Council, but the whole of the corporations. It commends the boldness of the champion, though fearing that the alliance of hostile interests will be too powerful. One thing is particularly worthy of remark, though we have often stated it before—viz., that, unlike the proposal for direct representation, the "indirect" or "collegiate" plan, as Dr. P. J.'s has been called, does not require any act of parliament to carry it out; while, were it once accomplished, it would at once afford the profession the opportunity, not only of pronouncing upon the desirability of further change, but of expressing its opinion upon all other questions.

The Erasmus Wilson Professorship of Dermatology.

Our readers are aware that the Royal College of Surgeons have accepted the munificent gift of £5,000 from Mr. Erasmus Wilson, for the purpose of founding a professorship of dermatology in the College,—of which the donor is a distinguished fellow. Mr. Wilson also gives a superb collection of models, which will, we anticipate, include duplicates of the whole of the specimens of the *Hôpital St Louis*, for we have heard that Mr. Wilson was the fortunate owner of all those duplicates. Such a collection will be worthy of a place in the great Hunterian Museum, and will, in fact, be a very important addition to that national monument of which we are so proud, while it cannot fail to advance dermatology by drawing to itself the remarkable specimens of other observers who wish to consign them to public uses.

The committee appointed to elaborate a scheme will present their plan to-morrow, and we have little doubt that it will be accepted. It must, of course, embrace the preservation of the dermatological department of the Hunterian Museum, and the regulations for the Chair of Dermatology. We have already said that Mr. Wilson imposed no restrictions on the election of a professor, and we may add that he requires that every registered practitioner shall be considered eligible. Such marked liberality is worthy of the age and of the profession, as well as of the department which the donor has made entirely his own.

A good deal of speculation has been rife as to the probable occupant of the new chair, and some very ridiculous and uncalled-for guesses have been hazarded. For our part we should hope that the College will have the good taste to invite the founder to deliver the first course of lectures himself. Had the chair been endowed by any one else, no one could show a better title to it than Mr. Wilson; and if he would consent to occupy it, no one would more worthily uphold the dignity of the professorship which must always be associated with his name.

Resignation of Mr Wilmot from the Council of the Royal College of Surgeons in Ireland.

We learn with much regret that Mr. Wilmot has intimated his intention not to present himself for re-election to the Council of the Royal College of Surgeons in Ireland, at the Annual Election in June. The announcement of this decision has been received with much regret by the Council, and a resolution was, we learn, adopted at their last meeting, expressive of their feelings at a severance of Mr. Wilmot's connexion with the College.

There is no member of the Council who has more thoroughly deserved, or more fully enjoyed, the confidence of the Fellows of the College, and there can be not the least doubt that if Mr. Wilmot had felt it possible to devote attention to his collegiate duties, he would have been placed high in the voting at the next election.

Sanitary Reform in Austria.

The Austrian Government, having entered on the Reform movement, is active in extending its efforts to medical matters. On the initiative of Dr. Giskra, the minister in charge of such subjects, a commission of forty-two medical men called from all the provinces of the Empire and chosen from the chief of the sanitary service, provincial medical officers, professors of medical schools, the medico-legal advisers of the Crown, civil practitioners, with the addition of five journalists, has been assembled at Vienna, on the 22nd of February, for the purpose of enquiring into the different branches of the medical service, and discussing and voting on the improvements and forms to be effected. It has been already decided to establish, by direct election from the medical body, Provincial Sanitary Councils for each province and district, who are to be re-elected every three years.

A superior Central Council of twenty-eight members, twelve of whom will be appointed by the Government, and will meet at Vienna to form a final judgment on all disputed questions. It is the intention of the minister to submit this project to the Legislature Chambers in the present session, so that it may not be indefinftely adjourned, but may produce an immediate result.

Coombe Lying-in Hospital, Dublin.

The guardians and directors of this institution, having recently purchased a plot of ground which adjoins and communicates with the hospital premises, and which presents a frontage of forty-two feet to Brabazon street, met on Thursday last, in the board-room of the institution, for the consideration of tenders for the erection of additional buildings thereon.

Sir Arthur E. Guinness, Bart., attended, and generously intimated his intention of carrying out the promise made by his late lamented father, Sir Benjamin Lee Guinness, D.L., M.P., and which had lapsed by his death—namely, to contribute the sum of £500 towards the erection of this building when proceeded with.

The plans, which have been prepared by the architect of the institution, Duncan C. Ferguson, Esq., provides for the erection of a building of four stories. On the first of these is to be placed ample accommodation for the general dispensary, consisting of large waiting room and apothecary's shop in the front, towards Brabazon street, and the physicians' room in the rear of, but communicating directly with, each of these two other apartments. On the next floor there will be a large ward, extending over both the dispensary waiting room and the apothecaries' shop, and a smaller one over the physicians' room. These two wards are intended for the reception and treatment of cases of chronic female diseases. On the third floor, the ward over the large chronic ward is to be appropriated for cases of the diseases of children, and the apartment over the smaller chronic ward is to be the operating theatre. The fourth floor is to be appropriated for the exclusive reception of contagious diseases; the larger ward for patients removed from the lying-in wards of the hospital, who are thereby separated from the more healthy patients, and the smaller ward for cases of infectious diseases in children. Each of the three lower stories will have a height of fourteen feet; the top floor will, in addition to that height of walls, have, by means of an open roof, an additional height of several feet. A bath-room and water-closet is to be attached to each story, and an unfailing supply of water is furnished throughout every part of the building, warm water being provided from boilers attached to the several fire-places. The ventilation is to be effected by the admission of fresh air in proximity with the respective floors, whilst the foul air is removed by means of air-funnels in the ceilings, which pass from front to rear of the building; in each of the contagious diseases wards, a range of louvres is to be constructed in the roof. The entrance to the dispensary will be from Brabazon street, while the upper portion of the building can be approached only from the yard in the rear, which opens into that of the hospital. In this way, the dispensary patients will be excluded from access to the other departments of the institution. There are to be two staircases, one leading to the chronic ward, the children's ward, and the operating theatre; the other, at the opposite side of the building, exclusively to the contagious disease wards, which are thereby perfectly isolated. The dispensary physicians' room, and the small wards over it, lie directly between these two staircases. The operating theatre will have a patent lift from the wards below for the diseases of females, and this will be furnished with a mattress fitted to a suitable operating table on castors, whereon patients can be conveyed from and to their respective wards without fatigue or hazard.

The guardians and directors have determined, in order to manifest their sense of Sir Arthur Guinness's liberality, to designate this building the Guinness Dispensary, in connection with the Coombe Lying-in Hospital. It is to be completed for the reception of patients within the next ten months.

It is expected that the guardians and directors will in a few weeks be enabled to proceed with the erection of the Guinness wing of the hospital, towards the expense of which the late Sir Benjamin Lee Guinness contributed the munificent sum of £2,000 shortly before his death, the law proceedings in connection with the title of the ground on which it is to be erected being now nearly complete.

University College.

LAST Wednesday afternoon the prizes in the Faculty of Medicine were distributed. Mr. W. Spottiswoode, F.R.S., took the chair. Mr. Grote, President of the College, and other members of the Council, and numerous visitors were present. Dr. Russell Reynolds, F.R.S., as Dean, read the report, which showed that 222 medical students were enrolled in the past year. The enlargement of the hospital was mentioned, and a feeling tribute accorded to the late Dr. Hillier. The chairman addressed the prizemen, and a vote of thanks to him proposed by Mr. Grote was carried with enthusiasm.

Health Resorts of the Metropolis.

THE death of Sir Thomas Morgan Wilson, which took place at Folkestone, on Wednesday last, must lead to some settlement of the long continued disputes as to the use of Hampstead Heath, which was left by one of his ancestors to his heir's male, to be kept open to the public.

The late Baronet for many years persistently endeavoured both in Parliament and in the Courts of Law to obtain power to enclose and build upon portions of the Heath, but was always successfully resisted by the surrounding landowners and inhabitants.

By his death, without issue, the entail lapses, and his successors are in a position to dispose of the land as they may think fit.

We hope the metropolis will not be deprived of this important lung—one of the most attractive spots in its suburbs—but there is reason to fear such eligible sites for building purposes will not be left unoccupied by the speculative builders who have already established themselves upon its borders.

Indeed, the foundations of houses, which the late Sir Thomas was restrained by the courts of law from erecting, remain on the highest part of the Heath, an irresistible attraction to complete the work.

We trust some steps will be promptly taken to secure at least a portion of this open space for the use and recreation of the inhabitants of London, crowds of whom daily throng the neighbourhood, and in fine weather literally go out to tea, hundreds may be seen partaking tea under the shade of the trees in the well known "Vale of Health."

Hospital Abuse.

A DISCUSSION has been again initiated in the *Times* on the abuse of hospitals by a very practicable letter of Mr. Holmes Cootes. So great is the abuse that prevails in all directions, that too much publicity cannot be given to the facts though we fear little can be done unless the profession fairly resolves to withhold its gratuitious labour.

Secret Remedies in Spain.

THE importation and sale of secret remedies into Spain have been hitherto positively interdicted by the laws and ordinances, one more stringent than another. Representations have, however, now been made by the apothecaries of Madrid that the restriction was prejudicial to the empire, the public health, and their own interests, and, in response, the Minister Sagasta has removed the prohibition by an order of the 12th of April. He defines a "secret" remedy as that of which the composition cannot be discovered, or of which the formula has not been published. All the provisions which impeded the introduction into Spain of foreign galenical products of known composition have been abrogated, subject, of course, to the payment of heavy taxes.

The Outbreak of Typhus in Spain.

THE epidemic of typhoid fever, or rather of famine fever, which rages in Spain, continues to increase in Madrid, and to extend its limits throughout the country. More than 12 physicians have died of it in the capital, 5 of them at the General Hospital, not counting 10 medical practitioners, 1 apothecary, and 21 nurses. Dr. Trelles, surgeon to the Medical Charities' Department, formerly physician to the Royal Family, and a practitioner of great celebrity has died on the 17th of April. Forty medical men have been already cut off in the province of Valencia, and the mortality is probably as great in other districts.

Election of Examiners in the Royal College of Surgeons in Ireland.

THE College assembled on Tuesday week to witness the annual election of examiners for the ensuing year. In addition to the seven examiners who offered themselves for re-election, there were five new candidates—Henry J. Gogarty, Charles Moore, Robert Murney, Richard Tuohill, and R. Persse White.

The three Examiners in Midwifery were unopposed.

In respect of the Examinership in General Education there was a sharp contest, which resulted in the removal of two out of three of the late examiners. No less than six new candidates presented themselves—viz.: Isaac Ashe, M.D.; Rev. A. Leeper, D.D.; William Roe, F.R.C.S.I.; George Scott, M.A.; Anthony Trail, LL.D., F.T.C.D.; Montgomery A. Ward, A.B., M.B.

For the selection of examiners seven councillors were chosen by lot, in accordance with the provisions of the charter, and retired for conference together. On their return the President announced the following gentlemen to have been chosen :—

Examiners for Letters Testimonial and Fellowship.—John Barker, Christopher Fleming, Benjamin W. Richardson, M. Harry Stapleton, Edward A. Stoker, T. Jolliffe Tufnell, and Edward S. O'Grady.

Examiners in Midwifery.—John Cronyn, Edward J. Quinan, and John R. Kirkpatrick.

Examiners in General Education.—Isaac Ashe, M.D.; Thomas Byrne; Anthony Trail, LL.D., F.T.C.D.

Our readers will observe that no change has been made in the constitution of the Surgical or Midwifery Court, and that Dr. Ashe and Dr. Trail, F.T.C.D., have replaced Dr. Murray and Dr. G. F. Shaw in the General Education Court.

PROFESSOR Humphry has been elected Honorary Fellow of Downing College.

DR. GREEN will not be opposed for the Assistant Physiciancy at Charing Cross Hospital.

DR. PAYNE obtains a similar post at the Children's Hospital.

DR. HOFFMEISTER will accompany the Queen to Scotland.

DR. CORFIELD, M.B., M.A., Oxon, formerly Radcliffe Travelling Fellow, has been elected to the new Professorship of Public Health, at University College, London.

DR. PALFREY will commence his course of "Clinical Lectures on Diseases of Women" at the London Hospital, on Tuesday next, the 18th inst., at 2.45 p.m.

THE new Lunatic Asylum for the counties of Cavan and Monaghan will shortly be opened for the reception of inmates.

MR. BLANCHARD Jerrold is at Brussels, on a journey through the poor districts and poor-law systems of Europe, to examine the results of their various modes of administration.

THE Pharmacy Act need give no more trouble to the minds of those who dispense their own medicines. It has been so amended in committee as to reserve the right of all registered practitioners.

ON Thursday last a Mr. Farmer was summoned before the magistrates at the Southwark Police Court by the parish authorities for non-compliance with the provisions of the Compulsory Vaccination Act. The defendant, who pleaded illness as the cause of neglect, was fined two guineas, which he paid.

A LIMITED number of copies of the following works by Sir George Ramsay, Bart., has been kindly placed by the author at the disposal of the Society of Arts, for distribution to such Institutions as may apply for them :—

1. Analysis and Theory of the Emotions.
2. Introduction to Mental Philosophy.
3. Principles of Psychology.
4. Instinct and Reason.
5. Essay on the Distribution of Wealth.
6. Political Discourses.
7. A Disquisition on Government.

Applications for copies should be made to the Secretary.

ACTIVE efforts are being made in Italy to ensure the success of the approaching International Congress at Florence. A circular has been addressed by the Ministers of Public Instruction to the doctors of all Universities soliciting the active co-operation of the Professors of the Faculty of Medicine in the Congress.

THE insubordination of students in the Continental Schools is becoming a very serious matter. We lately reported the closing of a Russian University in consequence of such an outbreak, and the same spirit has recently manifested itself in another form in the Paris Faculty of Medicine.

The students in medicine have evidenced a dislike to M. Regnauld, the Professor of Materia Medica in the Faculty, in consequence, it is said, of his severity in the examinations. They manifest their objections by creating such a riot at his lecture, that he has been unable to complete the course, and has been obliged to omit the concluding lectures.

Medical Gleanings.

ON THE BLUE LINE IN SATURNINE AFFECTIONS, AND ITS PATHOGNOMONIC VALUE. BY DR. FALOT.

DR. FALOT refutes the authors who believe that the blue line along the gums is formed by an accidental deposit on the buccal mucous membrane of lead furnished by dust contained in the air or food, or still more in fluids that have been adulterated or accidentally charged. According to M. Grissolle among others, the blue line is the livery of the lead-worker, not a symptom of poisoning, but a simple deposit, and a sign of the worker's occupation. M. Falot quotes the observations of Beau, Barlow, Gregory Smith, and Lecoq, all of whom observed the blue line in patients undergoing an internal treatment with pills of subcarbonate or acetate of lead; and he gives in addition the reports of some cases of his own, which were gathered in an epidemic of colic in a ship's crew at the Gaboon, the cause of which was lead poisoning. Finally, after having established by experiment the impossibility of reproducing the blue line artificially, by touching the gums corresponding to the incisor and canine teeth of the lower jaw with a brush dipped in acetate of lead, and after having proved that oxygenated water and water sharpened by sulphuric acid, the ordinary reagents of lead, had no influence upon the blue line when it is plainly established, Dr. Falot proves that the line is the result of an elimination of the lead, and indicates by its manifestation that the lead, carried along by the circulation, comes to be deposited in the tissue of the gums, where it forms a combination which reveals its presence by a more or less intense blue coloration. M. Falot finishes his contribution by representing the blue line as a sign of the penetration of lead into the economy, and he derives the important conclusion for forensic medicine, that its presence may denote lead-poisoning, although an analysis of the viscera may not have revealed the smallest trace of the metal.

STATISTICS OF PARIS.

In a paper read before the French Academy of Medicine, by M. Gustave Lagneau, we find the following curious remarks concerning the population of Paris. That of the department of the Seine increases in a ratio nine times larger than that of France, a circumstance naturally owing, not to the difference between the number of births and that of deaths, but to the excess of immigration over emigration. About one-third of the children born in the department of the Seine are sent out to nurse in the others; only one-third of these infants ever return home. From the ages of ten to fifteen for boys, and fifteen to twenty for girls, an immigration towards Paris sets in, which seems to attain its maximum within the ages of twenty-five to thirty. It is so considerable as to embrace nearly two-thirds of the population of the department of the Seine, only one-third of which is really indigenous. In consequence of this double current of emigration of infants and immigration of adults, the Seine differs from all the other departments of France in its having a smaller proportion of infants; a greater one of grown-up persons; a smaller one of married couples; and consequently a larger one of bachelors and spinsters. And now we come to a point at which the author of the paper wanders into the Darwinian system. This constant immigration, he contends—of generally intelligent persons, capable of contributing to the constant advancement of commerce, manufactures, the arts and sciences, of which Paris is the principle centre—seems to explain why since the twelfth century, according to Dr. Broca's observations, the capacity of the skull and the breadth of the forehead have materially increased. To this view of the case it may be objected, that since two-thirds of the skulls one might meet with in Paris are those of foreiguers, there are two chances to one against the validity of Dr. Broca's conclusions. The mortality of children under five years of age amounts to one third in the rest of France; in the department of the Seine it is more than one-half. Again, in this department, mortality generally is one-third greater than elsewhere in France; at twenty, the survivors are only two-fifths of the number born; at forty, less than one-third; and at sixty, less than one-sixth. *Galignani.*

CAUSES OF CHOLERA.

PROFESSOR Pettenkofer gives the following as a summary of his elaborate investigations in the causes of cholera:

In my opinion four conditions are essential in order to bring about an epidemic of cholera:

1. A specific germ.
2. Certain local conditions.
3. Certain seasonal conditions.
4. Certain individual conditions.

I have not investigated the nature of the cholera germ as disseminated by human intercourse. I have only taken for granted that it exists in the intestinal discharges of persons coming from infected places. My own investigations have been chiefly confined to the second and third before-mentioned conditions. Hitherto I have considered the human subject only so far as he is the bearer of the infecting matter of cholera or of the germ of this matter; and have with facts contended against the pure contagionists, who declare that the infecting matter is produced by a process of multiplication within the bodies of those affected by the disease. My chief proofs of this have always lain in simple *facts* (independent of any theory) as to the spread of cholera over large districts. There are certainly *places* enjoying complete immunity from cholera, also *periods* of immunity. The development of epidemics, and the immunity of many places, is totally inexplicable, by the simple assumption of contagion from person to person. Observe the spread of epidemics along the course of railways and other ways of inter-communication. Nor are they to be explained by certain individual disposition of person (food, drinks, domestic arrangements, age, position, &c.); but the circumstances require, besides these, the existence of local and seasonal aiding causes, which have to be assumed.

Are these in immediate relation to the cholera germ itself, or to the individual disposition? Facts speak in favour of the first opinion only. 1. Persons from an unaffected place going to an affected one, are attacked quite as numerously and as soon as the persons who constantly reside in these places. 2. Cases are on record where a person from an infected district conveys (in a way not clearly ascertained) infecting matter in a place enjoying complete immunity from cholera; and there, by means of his limited amount of infecting matter, infects a few persons who themselves had never been subject to the local conditions of an infected place, and therefore could not have had their individual disposition altered by it. Facts imperiously demand that we should consider that the "seasonal" and "local" conditions are intimately connected with the cholera germ, although they may, in addition be in a condition to act on the predisposition also.

The infecting matter, in my opinion, is not a product of the human intestines, but of the soil. In so far as we consider the cholera germ of an organised nature and capable of various degrees of development, it is possible—nay, very probable—that there may be various degrees of infection. The distinction between cholera "germ" and cholera "infecting matter" must be noted. The cholera germ stands in the same relation to the infecting matter as the seed does to the fully developed plant.

THE USE OF CHESNUT-LEAVES (CASTANEA VISCA) IN WHOOPING COUGH. BY J. LUDLOW, M.D.

IN the treatment of this very fatal disease to childhood, I have always wished for some agent or remedy to relieve that most urgent of all symptoms in the second stage, the spasm that is so trying to the sufferer, and to which the patient often succumbs.

I, like the drowning person who grasps at every straw, have tried all the various remedies that have been recommended by the best authority, from time to time, from all of which I obtained some assistance, but not one of the many met my desire.

More than two years ago the remedy placed at the beginning of this article was brought to my notice by a professional brother of this city, Dr. Unziker, he telling me that in his hands it had never failed to *cure*, not *relieve* the spasm, and bring the disease to a speedy end. I therefore determined to give it a fair trial whenever opportunity offered, and in every case that I have treated since, I have invariably used it, and with the happiest results. I have found in all cases that it would in from five to ten days, relieve the spasm, and in about two weeks cure it; and the little sufferer would whoop no more, but go on to a speedy recovery, to the great delight of myself and its friends.

I make an infusion of the leaves, by taking one-half of an ounce of them to the pint of boiling water, and afterwards add a pint of cold water, to which is added sufficient of white sugar to make it palatable to the patient, and give of this *cold* as much as I can get the patient to take during the day and evening. Giving it to drink in place of cold water, the child soon gets to like it, and I have no trouble in getting a sufficient quantity taken to produce the desired result. This remedy I believe of such importance, that I would urge it upon the attention of the profession at large.—*Cincinnati Lancet and Observer.*

CONGENITAL ARTIFICIAL ANUS AT THE UMBILICUS.

I WAS called during the month of April last to visit a female infant, seven days old, of mixed parentage, and was informed that the midwife thought it very strangely affected about its navel. On my arrival I removed the bandages and dressing from the cord and the first thing that saluted me was a considerable discharge of flatulence through the umbilicus. Upon further examination I ascertained that the cord had separated as usual, except it had left an ulcerated surface, and from this surface during my manipulatians the child had a copious operation. I next looked for an imperforate anus, but found everything in that locality in a state of perfect conformation, and the child still passing a portion of its stool *per via naturales.*

I cauterized the opening pretty freely with nitrate of silver, thinking by this means to excite an adhesive inflammation and thus obliterate the aperture. This did not accomplish the desired object, and I next ligated the funis a second time, hoping to detach another portion and leave the remainder impervious. This last treatment suceeded. Never having seen a case of the kind before, or remembered to have read of one, I proceeded to examine the authorities on the subject, and, after considerable search found one case recorded, in which it was thought that the ligature was applied too near the abdominal walls, and included a portion of the ilium at this region. This I do not think could possibly have been the fault here as the cord was properly tied two and a half inches long.

Query.—Could not the conduit to the vitelline sac have been left pervious as a remnant of intra-uterine structure.

Medical News.

MEDICAL CLUB.—(Communicated.)—The usual monthly dinner took place at the Medical Club on Wednesday last, Dr. Richardson, F.R.S., in the chair, the party consisted of between thirty and forty, and amongst the visitors and members present were Professor Macdonald, Mr. Joseph Knight, Mr. Marshall, President of the Medical Society, Sir William Fergusson, Sir Charles McGrigor, &c. Dr. Richardson, in proposing "Success to the Medical Club," said that the Club, though by name Medical, was in fact cosmopolitan in its cha racter. No eminent man in science or in literature was excluded because he was not medical ; on the contrary, the promoters of the Club had done all they could to remove every trace of a narrow and exclusive spirit. At the same time they were satisfied that medicine alone presented a basis sufficiently broad, sufficiently scientific, and sufficiently social on which to place permanently an institution such as the Medical Club claims to be, and is, and is to be. Medically, the Club was a centre for the representation of physic in all parts of the empire, and every man known and unknown who joined it was sure, whenever he was able to visit the Club, to make some new friend and receive some new social advantage. The monthly dinners tended effectually towards this every desirable object of bringing members of the profession, who were widely separated at most times and seasons, into friendly communion, and of making them acquainted also with men of mark and stamp in other professions. The gradual and safe increase of members showed clearly that the principles of the Club were sound, and nothing now was required but time and patience to perfect what had been so happily conceived, and up to this time so faithfully carried out. The Chairman, in conclusion, said he had hoped when the return of Dr. Livingstone was a short time since announced, that the meeting this month might have been graced by the presence of the illustrious explorer. Had it been so, there can be no doubt of the welcome that would have been tendered him in the Club, and he, the Chairman, yet hoped that one day the members would have the happiness of being able to offer a home to a traveller whose work was so pure a glory to the profession he adorned. The finances of the Club he was happy to say were in a satisfactory state, and he had great pleasure in stating that at the next dinner, which would be on Wednesday, June 2nd, Mr. Erasmus Wilson had kindly consented to preside.

THE GERMAN HOSPITAL.—The twenty-fourth anniversary festival of this charity was celebrated at the City Terminus Hotel last Friday under the presidency of the Earl of Shaftesbury, who was supported by his Excellency the Count Bernstorff, and other distinguished persons. During the past year, there was an increase of 74 in the number of in-patients, and of 3,526 in the out-patients. The receipts of the institution for general purposes amounted to 5,523*l*. 14s. 9d. last year ; so that on the 31st December there was a balance due to the bankers amounting to £184. 3s. 3d. the subscriptions and donations awarded were nearly 4,000.

ROYAL FREE HOSPITAL.—This hospital founded in 1828 on the principle of free and unrestricted admission according to the report admits as in-patients about 1,500 persons annually, and more than 60,000 out-patients at a cost of about £7,000 per annum. The income of the charity from annual subscriptions is not more than £1,500 ; leaving the large balance of £7,500 to be raised by means of special appeals. The forty-first anniversary festival was held last Wednesday, at the City Terminus Hotel, under the presidency of the Lord Mayor (Mr. J. C. Lawrence, M.P.), and the company included Viscount Sidmouth, Viscount Dupplin, Sir George Bowyer, Mr. Sheriff Hutton, the Rev. J. B. Owen, the Rev Mr. Mitchell, Dr. Rickards, Dr. Lloyd Owen, Dr. O'Connor, Mr. Sarjeant Robinson, Mr. C. Candy, Mr. S. H. Northcote, Mr. Gilbert Northcote, Mr. Weedon Cooke, Mr. De Meric, Mr. S Rosenthal, Mr. H. S. Bicknell, Mr. E. Masterman, and Mr. W. S. Pritchard. In proposing "Prosperity to the Royal Free Hospital," the chairman called attention to some significant facts in the history of the institution. In 1828, the first year of its existence, 926 sick persons were relieved. Ten years later, in 1838, the number of persons who had availed themselves of it had increased to 8,200. In the last year of the next decade no fewer than 28,600 were relieved, and the number rose to 40,000 in 1858, and to 65,000 in 1868. In conclusion he made an earnest appeal on behalf of the charity, and the secretary subsequently announced subscriptions amounting to nearly £5,000.

EAST LONDON HOSPITAL FOR CHILDREN.—The annual general meeting of the East London Hospital for Children and Dispensary for Women, at Radcliffe-cross, was held on Wednesday, the 28th ult., Lord Enfield M.P., in the chair. The report, stated that since the foundation of the hospital, in January, 1868, the number of in-patients had been upwards of 800, and of out-patients 4,624. The number of beds had increased from 10, with which the hospital was opened, to 40. The expenditure during these 15 months had amounted to £1,653 18s. 7d., a sum which, considering the requisite preliminary expenses for furniture and fixtures, and allowing 8d. per head as the *minimum* for out-patients, reduces the cost for each child treated in the wards to £4 13s. 6d.

THE British Consul at Charleston, reports that the health authorities in that port have issued quarantine regulations for the ports of Georgetown, Charleston, and Hilton Head, on the coast of South Carolina, to the following effect :—1. That all vessels from any place where pestilential, contagious, or infectious disease existed at the time of their departure, or on board of which any case of such disease shall have occurred, arriving between the 1st of May and the 1st November, shall remain at quarantine for at least thirty days after their arrival, and at least twenty days after their cargo shall have been discharged, 2. That all vessels from any port in Asia, Africa, or the Mediterranean, or from part of the West Indies, Bahama, Bermuda, or Western Islands, or from any place in America south of Hilton Head, and all vessels on board of which, during the voyage, or while at the port of their departure, any person shall have been sick, arriving between the 1st May and 1st November, shall, on arrival at the quarantine ground, be subject to visitation by the health officers, but shall not be detained unless they shall have had on board during the voyage some case of infectious, contagious, or pestilential disease ; and 3. All vessels navigated by steam shall be subject only to such length of quarantine and regulations as the health officers shall enjoin.

STRYCHNINE POISONING.—The coroner for Lynn, held an adjourned inquest on Wednesday, on the body of the infant daughter of Mr. A. F. Langford, a chemist in the town. It appeared from the evidence that Mrs. Langford the mother of the child, has for the last six months been in very low spirits. She imagined that her husband's business had fallen off, and that he was on the brink of poverty. At the time of her confinement she had complained of pain in the head, and was much excited. On the 26th ult. Dr. Lowe, the medical attendant of the family, was sent for to see Mr. Langford, who was said to be dying. He found him in bed, suffering from convulsions, and on asking his wife when they came on she said she had poisoned herself and her husband with strychnine. She had just said this when she was herself thrown into a strong tetantic convulsion. Remedies were at once administered, and both Mr. Langford and his wife recovered. The deceased child was found in its cradle, strongly convulsed ; the stomach pump was at once used, but it did not recover. The contents of various parts of the body were sent to Dr. Letheby, of London, who found strychnine in the stomach, and gave his opinion that the child had died from its effects. He did not think the child would absorb the poison through the breast of its mother. He never heard of such a case, but it might be possible. Mrs. Langford, sen., who sent for the medical men on the 26th ult., stated that on the morning of that day she was sent for to see her son. Mrs. Langford, jun., put her arms round her neck and said, "Oh, Mrs. Langford, forgive me ; I've poisoned myself and poisoned them." The jury returned the following verdict :—"Died of strychnine, given by the mother while in an unsound state of mind."

ROYAL VISIT TO THE CHILDREN'S HOSPITAL IN GREAT ORMOND STREET.—On Monday the Prince and Princess Christian paid a visit to this institution. Viscount Gort and Sir William Jenner, received their Royal Highnesses, and the resident medical officer, with the secretary, Mr. S. Whitford, were in attendance, and after inspecting every part of the building, expressed approval of the arrangements. Her Royal Highness the Princess Christian, has for some years past, been one of the Vice-Patronesses of the Charity.

NOTICES TO CORRESPONDENTS.

SPECIAL NOTICE.

We propose in our next to recommence our investigations on the composition and uses of various "Foods and Drinks" most generally known in this country, of which we have not treated in former analyses. Our attention will first be directed to mineral waters, cocoas, mustards, &c. The gentlemen engaged in these reports are in the front rank of modern analysts, so that our readers may depend upon these reports for accuracy and impartiality.

MR. NOURSE, F.R.C.S., Brighton. Your letter upon Dr. Drysdale's theory of overpopulation arrived too late for insertion in the present number. It shall appear in our next.

DR. DAVEY, Walmer, will please receive our best thanks.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,

Deputy Inspector-General of Hospitals.

(Continued from page 367.)

HEPATITIS.

Featherstone, 10th Foot, aged twenty-nine, eleven years in the service, arrived in India late in 1842; shortly after landing suffered from dysentery, from which his recovery was incomplete, inasmuch that he had occasional recurrences of the disease from that time to 1845. During that and the following year he accompanied his regiment on service against the Sikhs, being, at Sobraon, shot in the leg and severely wounded by a sabre cut in the head, he killing his adversary as he fell. From these wounds, however, he recovered, and for the two following years, during which he was present with his regiment at Meerut, retained good health, and was free from any return of his dysentery. In 1848, the regiment being quartered in the citadel of Lahore, he for the first time experienced symptoms of "liver disease," and in that year sustained an attack of the disease, on account of which he was three months under treatment. On being discharged from hospital, he accompanied the regiment to Moultan, and during the whole of the campaign against that fortress enjoyed good health; he subsequently accompanied the corps to Ferozapore, and in 1850 to Wuzzeerabad. Towards the latter end of that year he suffered at that station from an attack of ague; in October, 1851, had a return of the disease, and in the succeeding month was under treatment for dysentery, but without any indication of liver disease.

On the 9th of February, 1851, the appearance of this man was such that Dr. Inglis, C.B., at that time in the 10th, remarked it during his ordinary inspection of barracks, and directed him to be sent to hospital. On being questioned there, he complained of a dull sense of weight and uneasiness in the region of the liver, and in the back; extending to the shoulder, increased on pressure, and attended by an irritable condition of the stomach; pulse was rapid, skin hot and dry.

On the 16th of that month, there was considerable bulging of the hepatic region, with a remote indication from elasticity, &c., of the formation of pus having taken place in the liver; he complained of constant pain in the affected side; the countenance was pallid, approaching yellow; appetite defective; strength prostrate; no febrile excitement. From this time he continued to manifest distinct symptoms of abscess in the liver, and the upper part of the right lobe was diagnosed as being its site.

On the 13th, a trocar and canula were pushed downwards into the projecting tumour from immediately below the false ribs; on withdrawing the canula, a spout of matter followed, and two pints of matter were in this way evacuated. A sense of relief was for a short time experienced, but he shortly afterwards complained of some degree of oppression in the right side of the chest, although a bandage had been applied in the ordinary way after the operation.

On the night of the 14th, he became restless; pain occurred in the abdomen; it soon became evident that the man was sinking, and during the night of the 15th he died.

Post-mortem appearances.—Although the canula had been retained in the wound, no attempt had been made at reparative action; the external opening communicated with a very large sac which occupied the whole of the right lobe of the liver, and an opening was discovered to have taken place spontaneously into the corresponding pleura.

The above case illustrates what has already been stated in regard to the insidious manner in which suppuration sometimes occurs, and as illustrating the ordinary progress of an unsuccessful case of the disease in question.

Murray, 10th Foot, admitted into hospital at Wuzzeerabad, 16th March, 1852, aged at the time thirty-two. He complained of pain around the umbilicus, which had come on without any apparent cause two days previous, and continued to increase in severity; his calls to stool were frequent, evacuations scanty and containing much blood and slime. Leeches were applied, calomel and opium administered, followed by a dose of castor-oil.

On the 18th, was reported as nearly free from pain, but passed a restless night; complained of thirst, and his pulse was somewhat excited; bowels only moved twice.

19th.—An attack of purging came on at three a.m., but was relieved by appropriate remedies; pain increased in the region of the stomach, and great irritability of that organ came on, so that for several days from this time the only medicines that could be administered consisted of effervescent draughts, a blister being applied externally.

On the 27th, slight tympanitis of the abdomen existed, but in other respects his symptoms appeared somewhat decreased in severity.

30th.—The report of his case records that during the previous three days he had a succession of chills, and that now distinct enlargement of the liver can be felt, and also indistinct signs of suppuration of that viscus detected.

About this time he stated that, shortly before his admission into hospital, he had, while in the act of lifting a heavy weight, tripped his foot, and suddenly felt as if something had given way in his middle; and he dated his illness from that accident.

No material change in his condition is recorded till the 1st of April, on which date the report of his case states that he was again seized with shivering, succeeded by a hot and a sweating stage; the tumour in the epigastrium had become more distinct than it had been, and nocturnal perspirations had set in.

On the morning of the 3rd, he had a very severe attack of shivering, and the tumefaction over the liver became much increased, filling up the entire space from the umbilicus to the ribs. The patient experienced no difficulty in lying upon either side. An operation having been determined upon, an oblique incision was made downwards and outwards from about an inch below the cartilage of the false ribs; the rectus muscle was divided, and a trocar and canula pushed upwards and inwards through the tumour the whole length of the tube. Forty ounces of pus, interspersed with clear glairy-looking matter, were at once evacuated, with the usual precautions, the canula being secured in the wound.

On the 4th, nine ounces of pus were in the morning evacuated, and six more in the evening, the dressings being soaked with bile and coloured yellow. He expressed himself as much relieved, and was in good spirits. An anodyne draught was administered, and during the succeeding night he had tolerable sleep.

On the 5th, about an ounce of blood-coloured matter was evacuated, and in the course of that day, while he was in the act of changing his position, the canula slipped from the wound; it was, however, replaced, and for the time no evil consequences appeared to result.

On the 6th, he was reported to have had a good night, to have slept tolerably well; two ounces more of matter were evacuated from the wound. The pulse was soft and of natural frequency; tongue clean. He was in good spirits, and expressed himself as feeling stronger.

According to the report of the 8th, he had been purged four times during the previous night. He had slept well for four hours, but unfortunately during that time turned awkwardly in bed, and instantly awoke, feeling that he had injured himself in the vicinity of the wound.

At the morning visit on the 9th, his features were observed to be somewhat sunken, but no other unfavourable indication for a time presented itself. The pulse was moderate; skin moist. About noon, unequivocal symptoms of peritonitis set in, and from that moment the case was considered as beyond hope; the new disease progressed rapidly, notwithstanding the use of as active remedies as the case admitted of. He gradually became more and more weak, abdominal pain ceased, and on the 14th, at five p.m., he expired.

Post-mortem appearances, seven hours after death.—Slight adhesions existed around the opening into the liver, the external orifice of that in the organ itself being dark in colour, and presenting a semi-gangrenous appearance; the entire lower aspect of the right lobe formed but a sac of an abscess, the cavity of which was sufficiently large to admit the fist. Its inner surface was lined with a layer of what seemed to be lymph, over which was a coating of dark offensive matter. No opening into the abdomen through the adhesions could be discovered, but the whole of that membrane was in a state of inflammation. The intestines were glued together in many places, and in the right hypochondrium suppuration had occurred in some of the glands. The other organs were not examined.

JAUNDICE.

Although the occurrence of jaundice among troops in India is by no means frequent, a considerable number of cases of the disease appear from time to time. In some cases, it occurs during attacks of acute hepatitis; more frequently it attends chronic attacks of the disease, while in others it presents itself unaccompanied by symptoms of either, although doubtless there exists in all a certain amount of deranged nutrition of the liver, of which the jaundice itself is a more attendant condition.

In a considerable number of cases of malarious fevers, jaundice exists as a complication of the general disease, and in a few the discolouration of the surface and conjunctiva is so great, while the period of evident pyrexia lasts, that persons so affected manifest symptoms approaching more or less closely those of yellow fever in the West Indies. This may be the case with, or in the absence of, symptoms of vascular engorgement of the liver.

It is by no means an easy matter in India, any more than it is at home, to form a correct opinion as to the precise condition upon which jaundice depends, or, in other words, its proximate cause—that is, whether it arises from suppression or retention and re-absorption of bile, as enumerated in the ordinary manuals. When I was surgeon of a regiment there, the method of Dr. Harley to distinguish these classes of cases was not known, at any rate by me, and I would here note them for the benefit of my successors. Jaundice from suppression, according to him,* is distinguished by the circumstance that only those products which exist preserved in the blood accumulate in the circulation, whereas in that from retention or obstruction, the products that are manufactured in the liver, equally with those preserved in the blood, find their way back to the circulation.

Considering the physiology of biliary secretion, and knowing the pernicious results that arise when the eliminating and transforming operations exerted by the liver upon the blood are ineffectually performed, it becomes a matter of surprise how little constitutional derangement attends the vast majority of cases of jaundice met with in India; slight indisposition, with nausea and anorexia, being perhaps the only accompaniments of the malady.

According to the statistics to which I have access, the greatest liability of men to the affection exists during the early years of their residence in India. I observe, however, that after the 10th Regiment had served five years in that country, and after being exposed to a severe outbreak of fever and dysentery, consequent upon occupation of very unsuitable quarters in the citadel of Lahore, a very marked increase took place in the number of cases of jaundice that for some time afterwards occurred. Thus, whereas from the time in question the yearly ratio of cases of the affection was no more than 2·50 per 1,000 mean strength, it subsequently rose to 13·0.

It seems to occur in somewhat larger relative frequency among officers than among men, is less than half as frequent among women as among soldiers, and is somewhat more frequent among children than among females of, and beyond, the age of puberty. Infants at the time of birth, in some instances, are jaundiced.

In some cases, biliary calculi are found in the gall-bladder of persons who have, during life, suffered from jaundice, and died of some other disease. The occurrence of these conditions, however, does not appear to be either constant or necessarily connected with jaundice; for while, on the one hand, that disease is found in persons who are subsequently found free from the presence of hepatitic or biliary calculi, so in others, whose gall-bladder is filled by those masses, no jaundice has been observed.

ON CANCER OF THE RECTUM.

By Holmes Coote,

Surgeon to St. Bartholomew's Hospital.

The rectum is not infrequently the seat of carcinoma, and, as in other parts of the body, so in this either soft cancerous growths may spring from the mucous membrane; or cancerous matter may be infiltrated among the tissues of the bowel, producing a general induration and thickening, accompanied by a narrowing of that part of the tube. We have in the museum a specimen in which distinct masses of soft, spongy, medullary substance have grown from the mucous membrane for about three inches above the anus; another in which, at about a similar distance from the anus, the greater part of the circumference of the intestine is occupied by a firm medullary tumour growing from beneath its mucous membrane. The mucous membrane is healthy. The tissues around that part of the rectum which is occupied by the morbid structure are thickened and condensed. The lymphatic glands behind the rectum are enlarged, and filled by a substance similar to that of which the tumour is composed. The patient, from whom this specimen was taken, was a woman of forty years, who died extremely emaciated, with medullary tumours in the liver and other parts, and who had made no complaint leading to a suspicion of disease of the rectum.

Infiltrated cancer, sometimes called "fibrous," approaches in character scirrhus of the breast. It may occupy at its commencement only part of the circumference of the intestine, where, its progress being slow, and a compensating dilatation being allowed by the unaffected portion of the tube, it may exist for a considerable time without interfering with the action of the bowels; nevertheless, it sooner or later involves the neighbouring structures—the bladder, or the vagina may become adherent, and similarly affected, or the rectum become fixed to some part of the pelvis.

A case of melanotic cancer has been recorded by Demarquay (*Journ. de Med. et de Chir.*, vol. xxxii., part 9). A tumour, the size of a hen's egg, protruded from the back of the rectum, above the internal sphincter. Demarquay detached the sphincter from the coccyx, and cut off the back of the rectum with the tumour, which he pulled down with a forceps. The bowel was then stitched to the skin, in order to avoid infiltration of the surrounding tissues by the fæces. Notwithstanding that several arteries were tied, so much blood was lost during the day that plugging was necessary. The patient died of exhaustion on the second day.

The usual seat of cancer is about two inches from the anus to the sigmoid flexure of the colon, and the disease is attended by such an amount of progressive narrowing, that often a passage of only a few lines diameter remains. In these cases the patient often obtains temporary relief by the ulceration and breaking down of the cancerous knots and deposits; the passage of the bowel is widened for a time, and the discharge of fæces is rendered easier. In other cases an artificial passage is formed between the healthy portions of bowel above and below the seat of disease—a tortuous, perforated, fibrous passage results, which in some degree obviates the distressing symptoms which would result from complete obstruction.

But in all cases the disease has a fatal termination. The patient may die from inflammation of the distended bowel, or general peritonitis; or from progressive marasmus; from a high state of tympanitis, interfering with respiration; there may be symptoms of fæcal vomiting, gradually increasing in severity.

It is said that inflammation of the bowel above the seat of stricture ensues as a consequence of pressure of the impacted fæces, and blocking of the blood-vessels. It involves all the tunics, and is characterised by enormous hyperæmia of all the vessels, and by a deep blue, or black hue of the gut itself. Both the mucous membrane and the sub-mucous tissues are infiltrated with the usual products of exudation, and often so as to become discoloured, soft, and friable masses. Peritonitis commences here, and spreads over the entire membrane.

The treatment must of necessity be only palliative; but we may soothe that which we cannot cure. A tube introduced through the stricture, by means of which the bowel may be washed out with warm water, gives an amount of ease to the patient which will be better understood when the effect of the mechanical impaction of the hardened fæces is brought to mind. With this warm water some preparation of opium may be mixed; or the same drug may be used in the form of a suppository. In some stages of the disease a bougie, carefully introduced, has relieved symptoms; and in all cases the proper regulation of diet is an essential indication.

Discharge from the rectum is often very offensive in odour during the stage of carcinomatous ulceration. The employment of Condy's fluid, and of other disinfectants, is here strongly indicated.

The idea that cancer of the rectum is in any stage a mere local affection is no longer entertained by any well-educated surgeon.

◆

OBSERVATIONS ON THE TREATMENT OF A CASE OF PSOAS ABSCESS.

By Thomas More Madden, M.R.I.A., L.K.Q.C.P., M.R.C.S. Eng.,

Assistant Physician to the Dublin Lying-in Hospital.

Many years ago, a case of the cure of a large psoas abscess by absorption was recorded by the late Mr. Wilmot (sen.) in the "Transactions" of the Dublin Medical Association for the year 1818, and the session before last a very interesting paper was read by Dr. Lyons, before the Medical Society, upon a case in which the matter was absorbed from the cyst of a large hepatic abscess, and the disease thus spontaneously cured. I now venture to think that the following case may also be of some interest, inasmuch as it tends to bear out the views expressed in both the papers I have referred to, as to the powers of the "vis medicatrix naturæ" to effect the removal of large collections of purulent matter from the system without any material aid from surgical interference.

On the 21st of November, 1860, I was requested by the late Mr. Cusack, who was unable to go himself, to visit a poor patient, named Joseph C. On reaching his residence, I found a boy, about twelve years old, lying in bed; his legs were drawn up; he was greatly emaciated, his limbs being little more than skin and bone; his eyes were pearly and lustrous, and the pupils were largely dilated; his pulse was quick, feeble, and compressible; the tongue was of a bright red colour, and his bowels were constipated. Notwithstanding this, however, his appetite was said to be very good, and his sleep was sound and natural. He complained of great weakness, and of some slight soreness and tenderness in the lumbar region. On making an examination over the seat of this uneasiness in the back—for it did not amount to pain—I found no appearance of spinal curvature; but there was considerable tenderness on pressure over the left transverse processes of the lower dorsal and upper lumbar vertebræ, and I could detect some fluctuation in the left groin.

The history of the case was as follows :—Six weeks before I saw him this boy had a severe attack of gastric fever, on recovering from which he complained of tenderness in the lumbar region. Mr. Cusack was consulted, and ordered poultices, quinine, and a generous diet. The symptoms continued to increase, however, until he was reduced to the state which I have just described.

The diagnosis was not difficult, for if not a case of psoas abscess, what else could this have been ?

The prognosis was certainly unfavourable. The patient was a delicate scrofulous child, already greatly emaciated and worn out by his previous illness. The circumstances in which he lived—supported by comparatively poor parents, who were often obliged to stint themselves in order to allow him the necessary nutriment, and living moreover in a densely inhabited court—were all against the probability of his recovery.

Treatment.—I ordered him cod-liver oil, a quinine mixture, and the most nutritious diet that could be procured. Two days later, his bowels being still confined, I prescribed a mild aperient pill, which produced such purging and weakness that I was obliged to check the diarrhœa it occasioned by astringents and aromatics.

November 28th.—The fluctuation in the groin has now become quite evident.

December 3rd.—He appears much weaker than when I first saw him ; suffers from night sweats, and is still losing flesh. Suppuration is going on slowly, and I directed poultices to the groin. I gave him claret freely, ordered sulphuric acid with the quinine, and larger doses of cod-liver oil.

8th.—Swelling in groin harder, and night sweats increasing. Medicines continued ; water dressing substituted for the poultices.

10th.—Pulse very small ; is worse ; stopped the quinine mixture, and gave compound tincture of bark in its place.

14th.—Pulse stronger ; abscesses larger and very tender ; no change made in the treatment.

On December 23rd, the abscess pointed and opened naturally, just below Poupart's ligament. There was very little discharge from it, but the boy complained much of the great pain it caused. I now consulted Mr. Cusack as to the propriety of making an opening in the usual manner into the abscess, but that eminent surgeon, with his usual wisdom, dissuaded me from doing so. "The boy will probably die in any case," said he ; "the opening will do no good, and if he dies after it you will only get the credit of killing him." I acted on this advice, and afterwards had reason to congratulate myself that I had asked it.

On January 4th, 1861, the abscess was discharging a little better ; the patient, however, presented very marked symptoms of hectic fever (night sweats, &c.), and complained loudly of the weight of the poultices, which had been constantly applied, as warm as he could bear them. I squeezed out as much as I could of the curdy ill-conditioned pus from the cyst, and made pressure over the lower part of it by straps of adhesive plaster. I also substituted the familiar soap and brown sugar plaster for the poultice. From the long-continued confinement to bed, a tendency to bed-sores on the spine was observed, for which a spirit lotion was directed. Steel wine, cod-liver oil, and bark, with sulphuric acid, were also prescribed.

On January 16th, he was nearly in the same state as he had been twelve days previously ; the discharge from the abscess in the groin was very scanty and sanious ; his urine was albuminous, and of low specific gravity. He was now ordered bark in powder, with a little rhubarb and magnesia, carrot poultices, and porter in place of claret. I had little hope, however, of benefit from these remedies, for the boy was evidently sinking rapidly, and it was only wonderful to me how a creature so reduced and debilitated lasted so long. It occurred to me, however, that this might be a good opportunity of trying the plan of treatment resorted to by Dr. William Hunter, in the well known cases of marasmus cited by Sir Thomas Watson, and accordingly I ordered a teaspoonful of olive oil to be rubbed into the inside of the thigh twice a day. The effect of this was most satisfactory, and my chief object in the present paper is to record my experience of the great efficacy, in certain cases, of this old-fashioned and now seldom employed remedy. From the day that I ordered these inunctions, the patient commenced to improve, and day by day regained flesh and strength, and, more especially the power of extending his legs, which previously had been drawn up and contracted under him.

On the 27th of January, he was better, and the colliquative sweats were much diminished ; but the orifice of the abscess was closing, and there was very little discharge, although there was evidently a great deal of pus in the cyst. I therefore introduced a tent into the opening. Having some slight diarrhœa, the powders were discontinued until that ceased. The inunctions were continued, and the quantity of oil rubbed in gradually increased to a tablespoonful each time.

On the 31st of January, he was better, and another tent was introduced.

February 4th.—The abscess had closed ; he was stronger and decidedly better.

7th.—The patient going on so well that I gave him leave to sit up for an hour on the following day. Syrup of bark was prescribed, together with tincture of the sesquichloride of iron, porter, and nutritious diet. From this time his recovery was rapid, and on the 27th of February, when he was able to walk nearly a mile to see me, there existed only some hardness, discolouration, and a slight depression to mark the site of the abscess. There was no tenderness in the lumbar region, and his general health was better than could have been expected, although his pulse was still quick and rather weak. A few months after this I heard that he was attending school, and from that time I lost sight of him till a short time ago, when a tolerably robust looking young man of eighteen came to consult me for gonorrhœa, and, seeing that I had forgotten him, reminded me that he was the boy I had attended seven years previously, and whose case I have just described.

The foregoing case presents, I think, some points not unworthy of consideration. In the first place, this was a case of perfect recovery from an advanced stage of a disease in which recovery is less frequent than an unfavourable termination. Secondly, the surgical methods of treatment usually recommended were not adopted in this case. Thirdly, the treatment which appears to have done most good was the use of the oleaginous inunctions.

That recovery is less frequent than the contrary termination in the advanced stage of extensive psoas or lumbar abscess is a proposition which few surgeons will dispute. I may cite the words of a surgical writer of great eminence in his day—namely, Mr. Kirkland—who, in his "Surgery," published in 1786, says on this subject :—

> "The most dangerous of all abscesses that belong to the abdomen is the lumbar abscess that forms in the cellular membrane about the psoas muscle, and points in the thigh, groin, back, or sometimes at the anus. Of these patients few, I believe, recover ; nor indeed is it to be expected, as the source of the disease can seldom be laid dry, and a caries of different parts of the back bone is sometimes added to the malady."

The second point I referred to, was that in this case none of the surgical methods of treatment usually recommended were employed. Modern practitioners appear to have no hesitation as to the propriety of operative interference in cases of psoas abscess, in the treatment of which the older surgeons considered it more advisable to content themselves with merely aiding nature's efforts to effect a cure. Now, however, some operative measure is generally resorted to in cases of psoas abscess. Either Mr. Abernethy's valvular opening into the cyst is made, or the small and repeated punctures suggested by the same authority, and more recently recommended by Sir William Furgesson, are tried ; or Mr. Vincent's revival of the operation proposed long ago by Deckers is essayed ; or the modified form of seton introduced by M. Chassaignac, and approved of by Mr. De Morgan is employed ; or else, perhaps, the plan of injecting the pyogenic cavity with iodine, as practiced in some cases by Mr. Coulson, is resorted to. The great English surgeons of the latter part of the last century, and of the early part of the present age were less bold, and yet perhaps, were not less successful, in their treatment of psoas abcess than their successors now are. Thus Kirkland, speaking of psoas and lumbar abcess, says—"Some, however, I have seen survive these collections of matter, by the tumour being suffered to break of itself, and its contents to drain gently off through a very small aperture, which prevents the free ingress of air and violent symptoms, for when a large tumour of this sort forms on the inside of the thigh, and breaks in a large opening, in such a manner that the air has ready passage, we frequently see a violent colliquative fever succeed, that closes the scene in a very short time."* The same opinion was also expressed by John Hunter.†

There are unquestionably many cases of psoas abscess in which each of the modern plans of treatment may be useful. But I would venture to say that in the majority of cases of psoas abscess, which generally occurs in delicate scrofulous children, it is better to trust more to nature and less to art, than is often done, and to content ourselves with aiding Nature's efforts by improving the general health of the patient. If we allow the pus to discharge itself by a natural opening, although the process may be very slow and tedious, we shall, I believe, find that, in many cases, the walls of the abscess will contract, and accommodate themselves to the gradually diminishing volume of their contents, so as to leave no vacuum for the admission of air, and the consequent ill effects which so often follow the artificial opening of psoas abscesses.

I have little doubt that in this case a considerable part of the pus contained in the abscess was not discharged from it through the opening in the groin ; but that purulent resorbtion took place. In my patient there was every local and constitutional symptom of a large collection of purulent matter, which was not, I think, accounted for by the discharge from the groin, and, therefore the cessation of those symptoms appears to be necessarily connected with the absorption and elimination of the pus through some other channel.

The third, and last point to which I shall allude, was the benefit derived from the inunction of olive oil in this case. The employment of frictions with oleaginous substances as a remedy has fallen into disuse at the present day, and yet there appear to be many cases in which this very ancient practice might still be resorted to with advantage. During the last eight years, since I experienced its efficacy in the case just described, I have used frictions with cod-liver oil, and I think with great benefit from the practice, in the treatment of cases of phthisis, when it was impossible to induce the patient to take cod-liver by the mouth and also as an adjunct to thq ordinary manner of using it. I have also prescribed rubbing in olive oil in cases of local paralysis, and muscular atrophy, in dysphagia, and in cases of torpid digestion from functional causes. I have succeeded in relieving pain and spasm in certain neuralgic and spasmodic complaints which have come under my treatment amongst the patients attending the Dispensary for Diseases of Women at the Dublin Lying-in Hospital, by ordering an ointment containing a very small quantity of opium, with a little unguentum hydrargyri nitratis, in a large bulk of spermaceti ointment, to be rubbed in over the seat of pain ; and the success which has attended this treatment, in some cases in which sedatives administered internally had failed to check the spasmodic action or to allay pain, I attribute almost entirely to the friction with the spermaceti, the amount of opium and mercury being too minute to produce much effect. There are many other diseases in which I think this remedy might be equally serviceable.

We have abundant proof how highly the ancients valued oleaginous inunctions as a means of preserving health. Friction with olive oil, was used by them before taking violent exercise to soften and strengthen the parts, and they, moreover, resorted to friction in the treatment of several diseases, and to this day their example in both respects, has been followed by almost every primitive race. So common was the practice of oleaginous inunction in ancient Rome, that, under the Empire, the citizens were provided gratuitously with the oil for the purpose, at the public baths, which were supported by the state.

In the earliest records of medicine we find mention of oleaginous inunctions being regarded as most important remedies. Even in the Grecian temples, where valuable therapeutic agents were employed, together with pretended supernatural means, we read that frictions with oily substance were used by the patients. Thus, Apollonius of Tyane, on being introduced as a patient into the temple of Ceres, at Patras, was rubbed over the head with a yellow ointment, until a dense vapour arose from the heated surface, and was then plunged into a cold bath.

I have collected these few references, which I might have extended very easily, were it not for the space they would occupy, merely to show what importance was formerly attached to a now almost forgotten remedy. I would venture to add, in conclusion, that it might be worth further trial, to ascertain whether or not its revival would be an addition to the therapeutic means at our command in certain cases.

ON PROSTITUTION.

By CHARLES R. DRYSDALE, M.D., M.R.C.P., F.R.C.S.
Physician to the North London Consumption Hospital, Hampstead,
late Secretary to the V. D. Committee of the Harveian Society
of London.

It is, as all members of the medical profession are now well aware, at present in contemplation by a bill before Parliament, to extend the provisions of what is called the "Contagious Disease Act of 1866," to the general or civil population of this kingdom. The result of this will be, if carried out, that to a great extent the French system, as it is called, will be introduced into this country. It is proposed, for example, that all prostitutes should be forced to come to periodical examination in any town, which shall adopt the Act, and shall be compelled to enter hospitals prepared for the purpose, if they are found suffering from syphilis or gonorrhœa, and made to stay in them until all contagious symptoms have disappeared. The majority of the members of the medical profession seem enamoured of this proposal and with their usual desire to get rid of the disease, a most disinterested one, they hope that the extension of this Contagious Diseases Act may much lessen the spread of what is certainly at the present time one of the most formidable foes to human happiness, the venereal disease, and above all, that pest, syphilitic contagion.

The writer of this paper yields to no one in his desire to see the contagious disease arising from prostitution stifled, and thus that dreadful evil syphilis, perchance, in the end stamped out. And yet, he is not, and has never been, as his friends know, by any means enthusiastic in his belief as to the results attained by the French system. In the great meeting of medical men from all countries in Paris, in 1867, he asserted his opinion in the presence of M. Ricord and a most distinguished auditory, that the French system of examination of prostitutes had not, as far as he could see, made syphilitic contagion a whit less common in Paris, then in London. This he asserted from his own experience of the hospitals of the two cities.

M. Auzias Turenne, a distinguished writer on syphilis also, said at the Congress, with much truth, that the police system of examination of prostitutes made the girls into a kind of "white slaves," and that it was quite incompatible with the ideas of democracy and individual liberty which the great revolution had made so widespread in Europe and America. With the views of M. Auzias Turenne, the writer greatly sympathizes. Were it, indeed, clearly and distinctly shows that venereal diseases could be stamped out by the system of police supervision and examination, it would not be possible, perhaps, for an adherent of the principle of utilitarianism (and the writer professes himself a humble follower of Mr. Mill in this, as in other points), to refuse his sanction to this infringement of individual liberty. But, on the contrary, he feels convinced that on the whole, those states will be found perhaps, to suffer more from syphilitic diseases, where the French system prevails, than those where freedom obtains. In speaking thus, it is not meant to say that bodies of men, such as soldiers, who are kept in enforced and most unnecessary celibacy, since standing armies are now known to be quite a mistake, as Prussia has proved, he thinks, may not be protected from disease by governmental regulations, as is now done and should have been done long ago at Aldershot, Portsmouth, and other military and naval stations. The whole system of standing armies requires revision, and in the meantime this kind of disease should not be allowed to decimate them, as it has hitherto done, owing to the silliness and superstition of our rulers. But, when we come to the civil population, other considerations at once arise, and other principles must be attended to, which, in the writer's view, far more than counterbalance any supposed power that the municipalities possess to stamp out syphilitic and other contagions by the aid of the police. In the first place, any one who has given mature consideration to the present condition of the female sex in this country, will see how unfortunate the condition of a vast portion of that sex is. The wages of labour for women of the poorer class is often so very low that one does not see how they are expected to live by it. I have repeatedly had before me, at the Metropolitan Free Hospital, girls whose earnings by the needle did not exceed three or four shillings a week. These women were necessarilly fed, in bad health, and in a deplorable condition. It is, of course, from this class, above all, that the class of prostitutes is fed. For to say that a woman would, of her own accord, take to the precarious subsistence of a prostitute in this country for any length of time is an error. To ameliorate then, in the first place, the position of the workwoman, is one of the chief elements in the stamping out of venereal contagion, a deeper question than the majority of our *confrères* seem willing to sound.

But, secondly, who is there among us, who has had much experience among prostitutes as patients, who is not well aware how impossible it is for these poor women, even when diseased, to get into a place of shelter and to procure medical treatment in such cases. The evidence given on this head by Mr. De Meric, Mr. Weeden Cooke, and others, to which we gladly add our own, shows often poor prostitutes with ulceration and other severe contagious symptoms of the organs of generation are compelled to pursue their avocations in order to live, and who, at the same time, would gladly enter hospital if they could. Surely it is a mockery to say that they *must* do so, before the voluntary system has been tried, and before hospital accommodation for these unfortunate women, who are the results of an imperfect knowledge of social science, has been provided. We beg the attention of our *confrères* to this latter point, which, indeed, they cannot but be well aware of.

It is very difficult indeed, well to define what is a prostitute. Many workgirls, in times of distress, become prostitutes for a month or two, and then, when times mend, they return to the workshop. How dangerous to class them, as is done in Paris, immediately with the prostitute class, and thus damn them perhaps for life. Prostitution, be it remembered, is not *a crime* by the statutes, and we have no right to assume tacitly, that it is ; and to watch over the prostitutes as we do over the ticket-of-leave man. Just think what an outcry there would be, if men, who frequented houses of prostitution, were put under police surveillance. And if this be true, what right have we, except on the principle of "might make right," to enforce such like regulations upon that sex, which already has so many political disabilities, and is so ill-paid and defenceless against the ills of humanity.

Besides this, there comes the further consideration, that prostitution is an evil which does not at all require to exist. To say that it does, is just like saying that "poverty must always exist." Both of these phenomena of civilisation acknowledge similar causes. Reverse the causes, their evils will disappear. The writer of these remarks has more than once, following in the footsteps of the illustrious Malthus, Chalmers, Whately, and J. S. Mill, endeavoured to show how poverty was caused in industrious communities like this almost solely by the over-rapid multiplication of the species ; or, in a word, that large families were the main cause of poverty and overcrowding. Prostitution also, is caused by low wages and large families, and the true remedy both for poverty and for prostitution, and thus the removal of contagious venereal diseases, is the advising of early marriages, small families, and facility of divorce. Early sexual contracts are quite essential to get rid of the evils of masturbation, as well put by Sir W. Jenner, (in his evidence before the House of Lords) but there is no need to be contented with prostitution and its evils, on that account. Early marriages we repeat, very few children, (indeed none at all perhaps, as frequently in France, for some years) and greater facility of divorce, as obtains at present in Indiana, U.S., and some of the States of North America, is, in the opinion of the writer of this article, the only real solution of the problem of stamping out venereal disease, which can bear looking into. All other plans have the fatal imperfection of either expecting far too much, or of inflicting much concomitant evil. We have, fortunately, had the experience of continental nations to point out to us the imperfection of police inspections of prostitutes. The writer appeals to his continental brethren for confirmation of his assertions. Let us not say we despair of stamping out contagion by voluntary means, by appealing to the hearts and intellects of our male and female citizens, before we have really given the matter any serious consideration. Above all, let us have no more asceticism. Sexual instincts are quite as legitimate as any other appetites, and must be met, not evaded, as we have hitherto done, with our usual dislike to positive truth. Marriage must be made *universal* and compatible with the interests of economy and population. And then, if such a day should ever arrive to our unfortunate race, prostitution and venereal diseases will be only matters of history, not as now, sad and afflicting realities.

◆

A METHOD OF MAKING THE INTERRUPTED SUTURE BY MEANS OF FINE SEWING NEEDLES.

By J. Lamprey, M.B., Surgeon 67th Regt.

Incised wounds, especially of the face and head, frequently claim the attention of the military surgeon, as soldiers, who are not less inclined to be pugnacious than civilians when intoxicated, very often, in their drunken brawls, receive wounds of so formidable a character that it is necessary to resort to sutures to keep the edges of the wounds in position. The kind of suture I hitherto had recourse to was made with the ordinary suture needle and silk thread, and this is perhaps still generally used by surgeons, notwithstanding the investigations of Sir J. Y. Simpson, who has pointed out the advantages of metallic wire over silk, or other organic materials for such a purpose.

It struck me, that the ordinary suture needle, which is also required in using fine metallic wire, and a very formidable weapon in its way, capable of making a considerable wound and giving rise to severe pain, might be dispensed with by using the finest sewing needles, and making them serve the same purpose as the wire or thread, in the manner suggested by the twisted suture, but with this difference, that instead of inserting the needles at the distance of half an inch or so from the edges of the wound, if I inserted them quite close to the margin of the edges and passed them through the cutis alone, without touching the deeper tissues, I could keep the edges of the wound in close coaptation sufficiently long to allow of immediate union taking place.

Accordingly, on the first occurrence of a case of incised wound, I inserted a fine needle, of the kind used in sewing cambric, through the margins of both edges of the wound, and bringing them together, I secured them in that position by passing a single noose of ligature silk from one extremity of the needle to the other in the manner shewn in the illustration, and taking care to avoid unnecessary pressure or constriction. At a distance of about three-eighths of an inch I inserted a second needle in a similar manner, and noosed it also, and again a third needle, and so on throughout the whole extent of the wound. I then removed by means of the cutting pliers both ends of the needles, merely allowing an eighth of an inch of the needle to project above and below the wound.

Showing the mode of inserting and noosing the needles.

Before inserting the needles, I applied a solution of carbolic acid diluted to 1-40 to the open wound, and when they were inserted I applied lint wet in the same solution, and covered all with a piece of gutta percha tissue. On the following day I removed the external dressing and withdrew the needles carefully, so as not to disturb the noose of silk thread which acted as a support to the recent agglutinating lymph holding the edges of the wound together. I allowed all to be exposed to the air by applying no further dressing, and in a few days, the nooses of silk thread being quite superficial fell off, leaving the smallest trace of a cicatrix behind. No discharge of pus or ulceration followed this proceeding. I have recently had some extensive cutaneous wounds, one of them a large scalp wound treated in this way, and the results were so satisfactory, that I have no hesitation in treating all similar wounds in the same manner.

The advantages of this mode of treatment appear to be as follows :—

1. The fine needles make the smallest possible wound.
2. They are inserted and remain so, thus causing a minimum of pain.
3. Their presence causes no irritation, consequently there is no secretion of pus or ulceration.
4. They are much more easily and expeditiously applied than other modes of making suture.

I prefer removing the needles on the following day, though if necessary they could be retained longer, but once immediate union is established they are no longer required, and should be removed at once. This removal is much facilitated by using only the pointed extremities of the needles, owing to their taper form, and with this view, I now only allow so much of the needle to project on the opposite side of the wound as will permit of the easy application of the noosing thread. I have also observed, that the longer the needle remains in the wound the facility of removing it becomes less, as the oxidization of the needle increases its size, and roughens it. Still a little rotatory movement will enable it to be extracted by the forceps quite easily.

Having seen so much benefit derived from the use of carbolic acid, I apply it in all cases to such wounds in the manner stated, as I consider it not only has valuable antiseptic properties but also prevents the formation of pus, and as it could not be applied to wounds kept together by adhesive plaster, these sutures are necessary.

From what I have observed in this mode of applying sutures to wounds of a superficial character, I should have no hesitation in adopting the same method for bringing together the flaps in cases of amputation, using if necessary, a stronger needle, and inserting it a little further from the margin, and using fine iron wire in lieu of ligature silk.

Hospital Reports.

METROPOLITAN FREE HOSPITAL AND FARRINGDON DISPENSARY.

FURTHER CASES OF SYPHILIS TREATED WITHOUT MERCURY.

By Charles R. Drysdale, M.D., M.R.C.P., F.R.C.S.,

and

Robert W. Dunn, Esq., M.R.C.S.,

A part of which was read at the Harveian Society on March 18, 1869.

(Continued from page 371.)

Case 52.—E. S., aged six weeks. The mother was syphilitic, and the child when born was very puny. Three weeks after birth an eruption broke out on the skin and the child snuffled, when it was treated by mercurial bandage and got rapidly worse. It then came under Mr. Dunn's care on December 7th, 1864. The child was then much emaciated, had diarrhœa, syphilitic eruption on the buttocks, legs, and face. Ordered to leave off the bandage and to take gr. ij. of chlorate of potash t. d. January 5th, 1865, child still purged; ordered some chalk mixture. January 12th, much better. Repete pot chlor. February 16th, pronounced well.

Case 53.—E. C., aged five weeks. Three weeks after birth a rash appeared and snuffles. A previous child of the mother had been under Mr. Dunn's care for the same disease. The mother, a strong, healthy woman, noticed no disease in herself; but the father had primary disease some years before marriage, but no secondary symptoms or other symptoms as far as he could remember. The patient was delicate, had snuffles, had also syphilitic eruption on buttocks, legs, &c. Ordered to take gr. ij. of chlorate of potash t. d., when first seen by Mr. Dunn on March 28th, 1865. The child was pronounced to be well on April 20th, 1865.

Case 54.—J. B., aged eight weeks, a delicate child from birth. The rash first appeared, with snuffling, when the child was four weeks old, on the buttocks first, and soon spread more or less over the whole body. This is the first living child the mother ever had. She had been twice married, but had no living children by her first husband, but frequent miscarriages, and had suffered from a rash on the skin and sore-throat. No trace of disease about the second husband. The child was first seen by Mr. Dunn, June 5th, 1865, and he ordered it to take gr. ij. of chlorate of potash t. d. The child was pronounced well on June 29th, 1865.

Case 55.—L. M., aged four months, was brought to the Farringdon Dispensary to Mr. Dunn for an eruption which appeared after vaccination, up to which period the child had been quite well. The matter used to vaccinate the child was supposed to have infected it. On careful examination, however, it was found that the father had suffered from syphilis two or three years before marriage, and had been treated by mercury and then by sarsaparilla. He had an eruption on the head and skin, and sore-throat, and had been treated with iodide of mercury at the Skin Hospital. The child had a syphilitic eruption on its head, face, and legs, and had snuffles. It was very emaciated and restless. Ordered to take a teaspoonful of a mixture of virum ferri and oleun morrhuæ t. d. The child was under treatment four months, and then was pronounced quite well. This was a case of syphilis called into activity by vaccination.

The following cases are cited in order to show in what cases of hereditary syphilis the mother may be expected to escape infection, and in what cases of maternal syphilis the child may escape.

Case 1.—Seen by Mr. Dunn. The mother being three months pregnant when first infected, was then treated by mercury. She had secondary eruption at the latter months of pregnancy. The child was born alive and first showed signs of hereditary syphilis when three months old.

Case 2.—Seen by Mr. Dunn. The mother, in this case, was infected by her husband during the second month of pregnancy. She had ulcerated sore throat, mucous tubercles on lips, and was treated by mercury and iodide of potassium. The child was born alive. It first showed signs of syphilis when it was one month old, when it was treated by hydrargyum cum cretâ and migentum hydrargyou nitrates. It first was seen by Mr. Dunn when two years old with mucous tubercles, and with a dry syphilitic eruption over the body.

Case 3.—Seen by Mr. Dunn. The mother in this case was infected by her husband when she was three months pregnant. Had syphilitic eruption before the child was born. The infant first showed symptoms of the eruption when it was four months old. The mother was treated without mercury.

Case 4.—Seen by Mr. Dunn. The mother in this contracted the disease during the fourth month of pregnancy, and was treated with mercury. The child first showed signs of the disease when two months old.

Case 5.—Seen by Mr. Dunn. The mother in this case contracted the disease at the end of the seventh month of pregnancy, and had eruptions one month after the birth of the child. The child was born healthy, and has remained so. Mother treated without mercury, is in good health.

Case 6.—The mother contracted the disease during the first month of pregnancy. The child was born alive ; but showed symptoms of hereditary syphilis, when six weeks old. The mother was treated without mercury.

Case 7.—The mother contracted the disease during the eighth month of pregnancy. The child was born alive, and showed no symptom of disease up to the age of two years. The mother had secondary eruption four months after the primary chancres, which were treated without mercury.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. Thornley Stoker, M.D., L.R.C.S.,
Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

MEATH HOSPITAL.

SOME CASES OCCURRING IN THE PRACTICE OF MR. PORTER.

Excision of Wrist Joint.

Cornelius C., æt. thirty years, was admitted into the Meath Hospital, April, 1869, suffering from extensive disease of the left wrist joint. The caries, which had commenced eighteen months before, seemed to implicate a great part of the bones forming the articulation ; there was much enlargement and discolouration of the surrounding parts, and several sinuses leading down to the unhealthy tissue. The man was otherwise in pretty good health.

On April 7, we had the advantage of seeing Mr. Porter excise the joint, operating by means of the lateral incisions recommended by Mr. Lister, and removing with some difficulty the end of the radius and of the ulna, and the first row of carpal bones.

There was little hæmorrhage ; only one ligature was required, any oozing being stopped by the douche of cold water which was used to wash the wound for the purpose of removing such detritus as might remain. A few points of suture were introduced to bring the edges of the incisions together, and the hand and forearm were placed on a splint well padded to fit the concavity of the palm ; the carbolic acid lotion of the hospital was applied as a dressing, and the man put to bed.

We saw the patient again on April 21st ; he had shown no unfavourable symptoms ; the incisions were nearly healed, having in some parts united by adhesive inflammation ; the sinuses were with one exception closed ; the wrist reduced very much in size, and the skin was regaining a healthy colour.

On the 6th of May, when we last saw the man, the wrist was greatly improved in condition, the sinuses had all closed, and the lines of incision were quite healed. He suffered no pain, and could to some extent use his flexor and extensor muscles, although the hand and forearm were still kept on a splint.

Wutzer's operation for the cure of radical hernia.

Pat Martin, æt. thirty, presented himself at hospital early in last April, suffering from an oblique inguinal hernia of the right side. It was of two years' standing, was reducible, and had not descended into the scrotum ; all which conditions being favourable, induced Mr. Porter to attempt its radical cure by means of Wutzer's operation.

On April 7th, he introduced the instrument, having smeared the cylinder with cantharides ointment, and did not remove it until the seventh day, when the invaginated portion of scrotum seemed well fixed in its new position; no impulse on coughing could be perceived. The cavity was plugged with lint until the twenty-third day, when a light truss was applied. The man was dismissed from hospital a few days afterwards, not having presented a single untoward symptom during his treatment, and being quite cured of the hernial protrusion.

Removal of a fibrous polypus from the back of the soft palate.

A. B., a healthy lad, æt. twenty, was operated on by Mr. Porter, on April 12th, for the removal of a fibrous polypus as large as a hen's egg, which grew from the back of the soft palate, and depended into the pharynx. A strong cat-gut ligature was passed by means of Bellocq's sound back through the left nostril, was removed from the instrument in the mouth, the loop carried round the tumour, and then tightened with a small canula and rack. The ligature was tightened each day until April 12th, when the tumour fell off, and the lad has since suffered no inconvenience.

MR. SMYLY'S CLINIQUE.

Nævi treated by electrolysis.

In the Medical Press and Circular for April 7th of the present year, we noticed a new galvanic battery introduced by Mr. Smyly, to replace the very large and inconvenient one of Althaus, which he was previously in the habit of using. We have on several occasions seen Mr. Smyly employing his battery in the treatment of nævi by galvano-puncture, and have also seen him using that of Dr. Althaus, and there is no doubt that the smaller and more convenient battery is also the better of the two, is more powerful, and yields most excellent results. Mr. Smyly has found this plan of treatment to afford, in some classes of nævi, infinitely more advantage than any other which he has tried. In those nævi situated in places where a scar would disfigure, it is particularly excellent, as it leaves very little mark, owing to the fact that the skin suffers but slightly from its action. In cases, also, where the nævi do not project above the level of the surrounding parts, and where consequently a ligature would be troublesome of application, or when they are in a situation where a like difficulty would occur, the mode of treatment by electrolysis is found to answer admirably.

In one case, that of an infant of nine months, on which we saw the two operations performed, the nævus was situated just beneath the inner canthus of the eye, was deeply seated, composed principally of large veins, and projected but slightly above the surface of the surrounding skin. The change which each operation produced in its appearance was very marked, and the hæmorrhage resulting from the puncture of the veins—the uncontrollable character of which, in such cases, everyone is acquainted with—was readily checked by increasing the strength of the current.

In one case on which Mr. Smyly operated successfully, the nævus, which was situated on the scalp, has since become covered with a crop of hair, showing how little likely the skin is to suffer any injury from the action of the galvanic current.

Our Analytical Department.

AN EXAMINATION AND ANALYSIS
OF
PULLNA WATER.

It is frequently found necessary to analyse mineral waters at stated intervals, simply because they change their composition, both qualitatively and quantitatively. These changes may proceed from volcanic or other alterations which are carried on subterraneously, and which are frequently not easily explained. Thus, Dr. Muspratt ("On Harrogate Waters," *Chemical News*, Oct. 2, 1868) has noticed that a considerable change has taken place in the composition of one of our most important mineral springs. Again, two years since, the writer of this report had occasion to examine the "Schwalheim" waters, and discovered therein lithia. Baron Liebig had previously examined these waters, and had not noticed the presence of that base. It was not probable that in this case any less care had been expended upon the first analysis, or that the lithia had suddenly appeared therein; but it was probably due to the fact that the spectroscope has placed within the hands of the chemists extra facilities for the detection of the rarer alkalies and alkaline earths. The whole of the mineral waters of celebrity should be examined for these bases, and it is also necessary that all springs which are resorted to as medicinal agents should be examined at intervals with a view to the point to which we first referred.

The water at present under consideration is termed, "The Bitter Water of Pullna," Pullna being situated near Brüx, in Bohemia. It was received in glazed earthen bottles, of forty ounces capacity, each bottle being secured by a lead seal marked, "*Püllnaer Gemeinde Bitterwasser.*"

It was found to contain—

Soda.
Potash.
Magnesia.
Lime.
Iron (trace).
Alumina (trace).

Sulphuric acid.
Chlorine.
Silicic acid (silica).
Phosphoric acid.
Nitric acid.

The water was carefully examined for the rarer elements, viz., lithium, cæsium, rubidium, &c., but there was no evidence of their presence. Its qualitative examination led to the following apportioning of the constituents. As regards this point, we were almost inclined to arrange them differently; but as the water had been examined some years since by Struve, we determined to leave the arrangement according to that adopted by him, for the sake of comparison. The water contains—

Sulphate of sodium	1093·43
Sulphate of potassium	40·635
Sulphate of calcium	23·539
Sulphate of magnesium	801·44
Chloride of magnesium	179·623
Nitrate of magnesium	3·001
Carbonate of magnesium	57·359
Carbonate of calcium	6·624
Carbonate of iron (ferrous oxide trace), with trace of alumina	
Phosphate of calcium	·068
Silica	1·952
Total solid anhydrous ingredients in the Imperial gallon	2207·671

The specific gravity at 60° Fahr. was 1026·5.

As regards the qualitative examination, our analyses only differs from Struve in the presence of traces of iron, alumina, and nitric acid; the two first might proceed from the vessels. In the quantitative examination, the total solid ingredients are decreased (Struve gives this water as containing 2293·9 grains to the imperial gallon), but there is an increase in the carbonates and phosphates. It also differs in the presence of nitrate of magnesium. In all other respects the water is similar.

As the specimens were bottled, it was not considered desirable to determine the amount of free carbonic acid present.

This water is what is termed a "bitter purging water," and may be considered a mild but efficient aperient, certain in its effects, and excellent in all those diseases where disturbed defecation exists. The bitterness is due to the large amount of soluble magnesian salts, which would be even more marked if it were not for the presence of the bicarbonates and nitrate of magnesium.

There is a general opinion that mineral waters cannot be made artificially so efficacious as those procured from the springs. This is, no doubt, true to a certain extent, particularly when applied to the more complicated waters.

The actual analysis does not always represent the composition of the original water, and there is at present a considerable amount of theory appertaining to the mapping out of the results of mineral water analyses. In the present state of our knowledge, much must be left to the diagnostic acumen of the analyst. This statement may be better conveyed by the following:—The centesimal composition of the residue obtained on drying down a mineral water may be exactly given, but how the molecules are grouped together in solution must be hypothetically given by the analyst. The results would frequently differ materially. The artificial waters are generally constructed upon the ultimate analysis without due regard to these points. One important peculiarity of Pullna water is its perfect freedom from copper and other deleterious mineral substances, which might naturally be present.

The principal agents for the sale of this water in Great Britain are—Messrs. Best and Sons, 22 Henrietta street, London; and Messrs. Thwaities and Co., 57 Upper Sackville street, Dublin.

THE RINDERPEST IN 1747.

The cattle distemper existed in England in 1747. A hundred thousand cattle died in Lincolnshire. An old diary says that "the Common Symptoms of this Distemper were a runing at the Eyes and Nose, hanging to the Ears, and a Scouring in the body, and sometimes bound, which I apprehend was according to the degree of the Feavour; it was thought infectious therefore a stop was put to holding any Fairs or Markets for the Sail of horned Cattle, near the Distemper, by an Order of Council which said Council ordered all Beasts, as soon as discovered to have the Distemper, to be removed from the herd they were in and immediately shot dead; their hydes cut and slashed in such a manner as to make 'em useless and then directly to be buried."

WEDNESDAY, MAY 19, 1869.

THE MEDICAL COUNCIL AND THE ACCOUCHEURS.

The Reform of the Medical Council has not yet reached the position of an exhausted topic. Every one has his own notion, and too many seem more anxious to promote their own views than to serve the profession. We have heard too much of class interests to be particularly gratified at the proposal of the Obstetrical Society to set up a representation of the special interests of accoucheurs. The Councillors are not sent as deputies of the two orders of physicians and surgeons, and if they were, the accoucheurs might be content to rank as one or the other. They will ask presently for the incorporation of a new college or hall. There is already a special diploma or two in midwifery, a circumstance to be much regretted. The violent people who continually anathematise specialism too often do much to create it. Not a few of them have contributed to sever obstetrics from the other branches of the art of healing, and by their ignorant outcry and prejudice are continually lopping off other branches from the goodly tree.

Every one who sees any defect in the Council, and proposing to redress it really advances the day of its reform. The accoucheurs, therefore, are doing a good turn for the reformers of the Council, although we trust they will never completely separate themselves from our common profession. It is as members of the body medical—not as mere men-midwives that they have earned their right to rank on an equality with all their medical brethren.

The very aim of their memorial, received by the Home Secretary last week, would at once be gained were the plan of reform we have advocated carried out. Let everyone have a vote for the representative of the corporate body that granted him his diploma, and if obstetric interests were neglected in the Council, the return of some one who understood them, would be certain.

The following is the memorial alluded to presented by an influential deputation :—

1. The Obstetrical Society of London begs leave most respectfully to invite the attention of Her Majesty's Secretary of State for the Home Department to the general defect in the constitution of the General Medical Council, resulting from the want of adequate representation in that body of obstetric medicine.

2. The General Medical Council is constituted of seventeen representatives, elected by the Universities, the Colleges of Physicians and Surgeons, and the Apothecaries' Societies ; by six nominees of the Government ; and by a president elected by the Council itself.

3. Owing to the constitution of the governing bodies of the Universities and Colleges, these bodies have always elected representatives who neither teach nor practise obstetrics.

4. Amongst the members nominated by the Government there is not one who teaches or practises obstetrics.

5. The result is that at the present moment the General Medical Council does not contain a single member who has ever been a public teacher of obstetrics, and only two or three members who actually practise obstetrics.

6. The position and claims of obstetric medicine in reference to the Examining Boards, and the licence to practise, are very unsettled : the provision of competent midwives for the poorer classes and the public services is in the highest degree unsatisfactory ; the encouragement of obstetric science, and the regulation of obstetric practice, are duties of undeniable importance to the public interest.

7. Your memorialists submit that these duties can hardly be efficiently discharged to the public interest, or so as to command the confidence of the great bulk of the medical profession, by a body from which teachers and practitioners of obstetrics are practically excluded.

8. Your memorialists therefore earnestly pray that the constitution of the General Medical Council may be so remodelled as to make due provision for the appointment of members conversant with, and capable of informing the Council upon, matters relating to the science and practice of obstetrics.

◆

MEDICAL TEACHERS AND HOSPITAL PHYSICIANS AND SURGEONS.

It is satisfactory that the remarks we made on this subject should have caused pleasure in many quarters, though in the few localities where selfishness has long prevailed the feeling has been one of intense vexation. It was natural for us to seize the occasion of the little incident respecting Dr. Beale's position to point out how often such narrowness has defeated its own ends, and allowed some of our best men to be lost to public institutions. We remain of opinion that the staff of every hospital should, as a rule, be chiefly occupied with the clinical department of instruction, and that the theoretical courses should be left for the juniors and for worthy men who may not be in the staff. We have been reminded that some schools of medicine are so entirely subjected to the hospital authorities that they may be said to be ruled by them, and in these the most illiberal rules prevail. No one can be associated with school or hospital who is connected with any other institution. It is not that special hospitals alone are discountenanced, but even sister general hospitals ; all connected with some of them are pronounced ineligible for appointments at others. This is surely going too far, but sometimes worse narrowness prevails.

A minor hospital or two have pronounced that their charities and their schools shall not be served by any one who serves a major. The absurdity of the thing can only be exposed by supposing examples of the practical working of such laws. It is as much as to say that Sir W. Fergusson should not be suffered to lecture on surgery to the half dozen pupils of an inferior school because he is surgeon to King's College Hospital; or that Sir W. Jenner could not prescribe for the out-patients of a smaller hospital because he is so favourite a clinical instructor, and is occupied at University College. We purposely take the names of men who have reached the "top of the tree," to show the folly of a spirit of exclusiveness which would restrict others in their work. A fortnight ago we showed that Dr. Beale's appointment to a chair in one of the English Universities should be a cause of pride to King's, where he has so long lectured, and that his giving up that part of his work was no reason why the hospital should be deprived of his services. We think committees, while anxious to secure the best men for their charities, should take care lest, in asking too much, they do not in the end defeat the cause they have at heart. Already medical officers do too much gratuitous work, and for that reason committees are apt to place too stringent conditions on the places to which they elect. Leave the other school, give up your other appointments, has been said not only to the pure specialist, but to men who cannot be ranked as such. After a time a step further may be taken. Hospital committees will say to candidates, not only give up your dispensary, or your special institution, or even your paid lectureship—that has already been said!—but give up your life assurance company, and perhaps then, after a short time of ignominious compliance, give up your private practice. Yes, the time seems coming when men shall be required to forsake father and mother, and wife and children, for the glorious privilege of serving an ungrateful public, by doing the hard work of carrying on a charity towards which the governors contribute a trifle from their abundance of filthy lucre. It is time that some one lead the way in a rebellion against the unconscionable tyranny of hospital boards, for which, from Hunter's time till now, our noblest brethren have toiled as slaves.

SCOTLAND.

THE HEALTH OF THE QUARTER.

The Scottish Registrar-General has issued his quarterly report, and it will be found as interesting as usual. We have not space to devote to the births, marriages, and other interesting particulars, but our readers will expect to have an account of the mortality of Scotland in the quarter, and to this we may fairly add the comments on the weather and the health of the people generally.

Deaths.—20,431 deaths were registered in Scotland during the first quarter of 1869, being in the annual proportion of 25·4 deaths in every thousand persons, or 2·54 per cent. The average mortality of the quarter during the ten previous years was 24·9 deaths in the thousand persons, or 2·49 per cent. The death-rate, therefore, has been very high.

In England, on the other hand, the mortality of the quarter was below its average, being at the rate of 24·8 deaths in every thousand persons, while the average of the quarter during the ten previous years was 25·3 deaths in every thousand. This fact shows that, though Scotland and England are closely adjoining, weather and other baneful influences act very differently on the health and lives of the inhabitants during the same period of time.

The death-rate in the various-sized towns and in the rural districts bore a close relation to the birth-rate in each during the quarter, being highest where the greatest number of human beings were massed together, and lowest in the sparsely inhabited rural districts. Thus, the proportion of deaths during the quarter in every thousand persons of the estimated population was 35·0 in the principal towns, 28·8 deaths in the large towns, 23·8 in the small towns, but only 18·9 deaths in the rural districts.

The same fact was shown with regard to each of the eight divisions of Scotland. In the sparsely inhabited Northern division, only 16·5 deaths occurred in every thousand persons, but 31·1 in the populous manufacturing and mining south-western districts.

Of the eight principal towns, the mortality was highest in Glasgow and lowest in Perth. Thus, for every thousand persons in each town, there died in the proportion of 22·3 in Perth, 26·4 in Leith, 27·2 in Aberdeen, 28·1 in Paisley, 32·3 in Edinburgh, 33·4 in Dundee, 35·8 in Greenock, and 39·8 in Glasgow.

Of the 20,431 deaths, 6,619 were registered in January 6,172 in February, and 7,640 in March; being at the rate of 213 deaths daily during January, 220 daily during February, but 247 daily during March.

Health of the Population and the Weather.—January and February were unusually mild months, the prevalent winds being from the south-west, with less easterly or northerly winds than has occurred for years—indeed there was no truly wintry weather during either of these months till just on their close. The health of the people was good during these months; there was less sickness, and the mortality was below its average. All this was reversed during March. On the 27th February the wind veered to the north and north-west, and the whole of Scotland was immediately covered with snow; the frost was often keen; and during the whole month of March the winds blew with biting severity from the north, varying slightly to north-east or north-west. The pernicious effects of these cold withering winds was instantly marked on the health of the people. Every disease increased in virulence and fatality; and though the inflammatory affections of the respiratory organs presented a very large increase of deaths, their proportionate increase was not greater than that witnessed among the zymotic class of diseases, which are too often considered to be dependent on causes different to those which induce or influence inflammatory affections of the respiratory organs. Scarlatina still continued to be the prevalent epidemic among children over the greater portion of Scotland, but in some of the northern counties measles was the leading disease. During March, bronchitic attacks were nearly universal, and typhus and enteric fevers increased in prevalence and fatality. Bowel complaints, also, were frequent during March.

THE MORTALITY IN GLASGOW.

A report has been submitted to theBoard of Police by Dr. Gairdner upon the health of Glasgow for the first quarter of the present year, with special reference to the high rate of mortality in March last. The death-rate per annum per 1,000 of Glasgow as given by the Registrar-General for successive weeks of the past quarter, has been as follows:—In January, 34, 35, 37, 38, 42; in February, 37, 38, 35, 40; and in March, 38, 44, 47, 46—These March rates being the highest experienced in Glasgow since 1865, when the rate for one week ranged as high as 48. In 1868, the deaths at all ages during the months of January, February, and March, numbered 3,528; whereas, in the same period of the present year they amounted to 4,613, being an increase of 1,085, or nearly 31 per cent. The deaths of children under five years during the same periods of the two years were 1,677 and 2,332, being an increase of 655, or about 39 per cent. Taking separately, the deaths occurring during the month of March 1869, the increase is more remarkable, being, in persons of all ages, 48 per cent; and in children under five years, 57 per cent. It appears that during

January and February the excess of mortality fell chiefly on children from two to five years of age, in the fatal month of March it was children of a still more tender age who were the sufferers. The deaths of children under one year in March of the present year, show an increase over those in the same month of last year of 56·6 per cent; those of children between one and two years, an increase of no less than 71·1 per cent. and those of children between three and five years, 43·5 per cent. Proceeding to an analysis of the pathological causes of the increased mortality, Dr. Gairdner confines his attention to the fatal month of March. He points out that among zymotic diseases, the most decided increase occurred in measles and typhus, the respective figures in measles in March 1868-69 being 24 against 71, and in typhus, 41 against 85. In tubercular diseases, the present year presents a decided increase, the excess of deaths being principally owing to pulmonary consumption of which 232 fatal cases occured last March, as compared with 189 in the corresponding month of the preceding year. It is among the diseases of the respiratory organs, however, that we find chiefly the explanation of the inordinate mortality of the month. In March 1868, there were only 218 deaths from diseases of that group, against 504 in March last; In the principal infantile diseases of the digestive organs, on the other hand, we find a decided decrease.

Dr. Gairdner next takes up the incidents of excessive mortality in the principal towns of Scotland, and finds that, in 8 towns, with the exception of Paisley and Aberdeen, there has been during the first quarter a decided excess of mortality in 1869, as compared with 1868. In Glasgow this amounted to 30 per cent; in Greenock, to 25; in Edinburgh, to 17; in Dundee to 14; in Leith to 13; and in Paisley to 7. To account for this high mortality in Glasgow and Greenock, the Registrar-General has advanced the theory of "northerly and easterly winds," but, Dr. Gairdner remarks it is curious that those two towns should have been sufferers from such a cause, while Aberdeen and Perth should have escaped. Again, it appears, that, while infantile deaths in the 7 towns formed 38 per cent. of the total mortality during the quarter, they amounted in Glasgow to nearly 51 per cent., that zymotic diseases were fatal in Glasgow to the extent of 38 per cent., against 18 per cent. in the seven towns, that diseases of the respiratory organs, excluding consumption, had a relative mortality of 26 per cent. in Glasgow (which in the month of March advanced to 28 per cent.), against 21 per cent in the seven towns. "What we have to deal with, then," says Dr. Gairdner, "in the following more strictly local researches, is the fact of an excessive mortality, due in part to zymotic diseases (measles, scarlet fever, hooping-cough, typhus), but swelled to a very remarkable degree in the month of March by a sudden development of acute respiratory affections especially among children of the youngest ages.

Dr. Gairdner says:—"I fear that a very heavy bill of indictment will lie against Glasgow for a long time to come, unless the Improvement Commissioners can find it consistent with their duty not only to make purchases with a view to the future, but also to begin the process of active reform, and especially to lead the way in building up houses for the poor upon new and better models. It is impossible to acquiesce any longer, without formal protest, in arrangements by which the proper influence of the Sanitary Department is systematically excluded, as it were from operations which may more than any others, affect the health and lives of whole generations of future citizens."

THE SOCIETY OF ANTIQUARIES OF SCOTLAND.

A MEETING of the Society took place in their Library, Royal Institution, on Monday, May 10—Mr. W. F. Skene, LL.D., Vice-President, in the chair. On a ballot, the following candidates were admitted—viz., Mr. John Chalmers, Castlebank, Merchiston, and Mr. Gilbert Goudie, National Bank of Scotland.

Thereafter the following communications were read:—

I. Remarks on some of the Vitrified Hill Forts of Scotland, with reference to descriptions of similar remains in Bohemia, in a communication to Mr. Stuart, from Dr. Ferdinand Keller, Zurich. By Mr. John Stuart, secretary.

A discussion ensued in which the chairman, Dr. Maclauchlan, Dr. Burton, Mr. Milne Home, Dr. David Laing, and Colonel Robertson took part. Mr. Home stated that he had examined several vitrified forts, and had found in some cases that the stones of which the walls were formed were different from that of the hills on which they were placed, and were brought from other localities. All the speakers agreed that the subject was one of great interest, and that a more general examination of the forts than had yet been made was extremely desirable.

II. Notice of a Pict's House, recently discovered at Westhill' near Dundee, with sketch and measurements, and of Stone Cists found at Fallaws, Monikie. By Mr. A. Jervisecoir, Mem. S.A. Scotland.

This house was accidentally discovered in digging a foundation, when it was found that part of it had been destroyed at an earlier time. Enough remained, however, to show its strict conformity to the plan and mode of construction usual in this class of buildings, of which several examples have been recently described by Mr. Milne Home and Lord Rosehill.

III. Notice of old Scottish Coins, recently found near Prestonpans. By the Rev. John Struthers, F.S.A. Scot.

A number of donations to the museum and library were announced.

THE NEW ABERDEEN PROFESSOR.—On Friday evening, Dr. Andrew Inglis was entertained at a dinner to commemorate his appointment as Professor of Midwifery in the University of Aberdeen, in room of the late Dr. Dyce. The chair was occupied by Dr. Burn, President of the Obstetrical Society, and Dr. John Duncan. Sir James Y. Simpson, Bart.; Professor Dickson, of Glasgow; Dr. Graham Wier, Dr. Pattison, Dr. Argyll Robertson, Dr. P. H. Watson, Dr. Granger Stewart, Dr. Keiller, Dr. Archibald Inglis, Dr. Menzies, Dr. R. M'Lagan, Mr. Annandale, Mr. Stevenson Smith, Dr. Chiene, Dr. A. G. Miller, Dr. Joseph Bell, Dr. Sidey, Dr. M'Donald, and others were present. The chairman, in proposing the toast of the evening, the health of Professor Inglis, said he was descended from four or five generations of medical men, and had been early destined for the medical profession. Professor Inglis, in returning thanks for the toast, expressed the gratification he felt at having succeeded in securing the good wishes of so many of his fellow-practitioners. The toast of the "Scottish Universities," was proposed by Dr. Matthews Duncan, and responded to by Professor Dickson, of Glasgow; "The Royal College of Physicians," was proposed by Dr. P. H. Watson, and acknowledged by Dr. Graham Wier; "The Royal College of Surgeons," by Dr. Pattison, and replied to by Dr. Joseph Bell.

ROYAL EDINBURGH ASYLUM.—Dr. P. Maury Deas, senior assistant physician in this institution has been appointed medical superintendent of the new Cheshire County Lunatic Asylum. The *Scotsman* says:—Dr. Deas is the fourteenth assistant who has left this asylum to become medical superintendent of other asylums in England and Scotland.

Notes on Current Topics.

Royal General Dispensary.

This, the most ancient of London Dispensaries, having been founded in 1770, has recently taken a step alike honourable to its management and to its medical officers, and from which we are convinced the institution will lose nothing. It has been decided to award the medical officers a small annual stipend, in recognition of their services both among the patients who attend for advice at the dispensary, and among those who have to be visited at their own homes. The hard-working physicians and surgeons who visit from house to house, in court and alley, to minister to the helpless sick, certainly are labourers who are worthy of their hire; and the knowledge that a small fraction of their annual subscription goes to pay their physicians and surgeons is a fact calculated to stimulate more numerous and liberal subscriptions from those of whom many know well enough what it is to be working for their daily bread.

Dr. Richardson's Lecture at the Polytechnic.

On Tuesday, May 11th, Dr. Richardson gave a Lecture on the Large Induction Coil at the Polytechnic Institution, illustrating the effects of the electric discharge on animals, and showing how death is caused by lightning.

The lecturer commenced by a few well chosen, and well deserved, compliments to the Directors of the Polytechnic, and to Professor Pepper and Mr. Apps, the deviser and maker of the giant coil, for their liberality and kindness in freely giving the use of their theatre and apparatus for the lecture. This done, amid much applause from the crowded audience, the lecturer proceeded to demonstrate the various forms of discharge that can be obtained from the coil, showing how there is the discharge of flame that burns and the intense discharge which kills.

This last form of discharge was shown on a rabbit and a pigeon, both these animals being struck dead by the discharge from a battery of Leyden jars. The first shock appeared only to paralyse or stun, for the pigeon after one shock, when removed and handled, was alive, but breathing slowly and with difficulty; in time it would recover provided it were spared a second shock.

In the instance of a pigeon killed by a third shock from the Leyden jar, the body very soon became quite rigid and stiff, in which state it was handed round to the audience for them to see it thus proved that death by electricity in no way prevents or retards the development of the rigor mortis.

In the case of a pigeon that had received the shock down one side only of its body, it was observed after death that this side became stiff and rigid, while the other was soft and flaccid.

It was also shown that the blood in these animals killed by electric shock became firmly coagulated after death; and to disprove the assertion that the bodies of those killed by electricity are wont to run into rapid putrefaction, the body of a pigeon was handed round that had been slain by the electric shock three weeks before, and now showed but slight evidence of decomposition.

At the conclusion of this highly interesting and able lecture, Dr. Forbes Winslow proposed, and Mr. Hunt seconded, a cordial vote of thanks to the Directors of the Polytechnic, which was acknowledged in a very neat speech by Professor Pepper, who made the welcome announcement that the Directors had invited Dr. Richardson to give a second lecture in their institution on that day three weeks. Instead, therefore, of giving the last lecture of his Summer Course at Hinde street on June 1st, Dr. Richardson will lecture at the Polytechnic Institution on that day.

West Kent Medico-Chirurgical Society.

On Friday, May 14th (Dr. Thorowgood, President, in the chair), Dr. Morell Mackenzie gave a most interesting and instructive demonstration of the use of the Laryngoscope before this Society.

After giving a short history of the first introduction of the instrument, Dr. Mackenzie proceeded to show the method of using various laryngeal instruments, mirrors, brushes, cauterisers, galvanisers, &c. He then invited the members present to see, in the cases of actual patients, examples of syphilis affecting the larynx, and instances also of cancer, laryngeal phthisis, and one case of growths springing from the vocal cords. Each of the members was able to examine these cases and compare them with admirable drawings by Mr. Lennox Brown, which were placed on the table.

The paper concluded with some practical remarks on treatment, insisting much on the importance of judicious local treatment of any ulcerations after the surface of these had been perfectly cleared. Dr. Morell Mackenzie stated that he rarely used the solution of nitrate of silver now, as he found it produced often sickness and much discomfort, which was not the case with solutions of the salts of iron and copper. The case of the man with ulcerated cancer of the larynx showed what good effect treatment can exercise even on this serious affection, there having been no attacks of serious hæmorrhage since the man came under treatment. It was mentioned incidentally that this man had applied to a general hospital in consequence of his throat symptoms, and after a period of varied treatment he was sent about his business as a "shammer." Laryngoscopic examination soon disclosed the real seat and source of the man's sufferings.

The thanks of the Society were most warmly accorded to Dr. Mackenzie, and also to his excellent coadjutor, Mr. Lennox Brown, for the useful and highly practical paper; and the last meeting this session of the Society came to a close.

The Health of Dublin.

In the Dublin Registration District, the births *registered* during the week ending May 8th, amounted to 145. The average number in the corresponding week of the years 1864 to '88 inclusive, was 169. The deaths *registered* were 132. The number in the corresponding week of the previous five years was 139. Eleven deaths resulted from scarlet fever, showing an increase of four as compared with the week preceding; the average number of deaths from scarlet fever for the corresponding week of the last five years was three. Three deaths were referred to measles. Typhus fever caused two deaths, typhoid or enteric fever three, and simple fever two deaths. The deaths of seven children were returned under the head of convulsions. Bronchitis proved fatal in twenty-two instances, and pneumonia or inflammation of the lungs in three. Paralysis was the cause of four deaths, and apoplexy of two. Disease of the heart contributed eleven deaths. Phthisis or pulmonary consumption was the cause of nineteen deaths.

Influence of Nutriment on Disease.

The *Journal Central de Medicine de Berlin* publishes *seriatim* the conclusions arrived at by Dr. Salisbury from a large number of experiments on this subject. They are as follows :—

1.—The continuous use of vegetable aliments, particularly of the leguminous and amylaceous plants, provokes constipation and a sort of scorbutic condition.

2.—The use of amylaceous plants causes a great variety of morbid condition ; for example, fibrinous deposits and embola in the capillary vessels, and congestion, inflammation, diarrhœa, and paralysis, as the result, and, at a later period, tuberculous deposits in the lungs, affections of the eyes and ears, and pains in the back and extremities.

3.—These symptoms may be advantageously met by having recourse to albuminoid aliments of animal origin, and especially by the use of salts of potash and iron which prevent coagulation of fibrin, favour the circulation of the blood, and render active absorption and intestinal secretion.

4.—The morbid states which we have enumerated are developed in armies on the field, especially when they are subjected to an amylaceous dietary.

5.—The officers, who have the privilege of varying their diet, are free from these accidents.

6.—When the nutriment is exclusively amylaceous or saccharine, constipation soon appears, and stomachic digestion is effected with difficulty.

7.—This constipation is not slow in engendering the products of fermentation, intestinal gases, and parasites in great number.

8.—This condition continues until diarrhœa sets in, and then small colloid gelatinous masses are found in the fæces in variable quantity.

9.—These are in no respect the cause of the diarrhœa ; they result from the production and metamorphosis of saccharine and fermentine matter. Once produced, these substances act as a true poison on the organism and aggravate the intestinal lesions.

10.—It is specially in the evening and during the night that the products of fermentation are developed in the intestines. Each day they increase. The continual excitement of the intestinal mucous membrane by the gases and parasites produces diarrhœa, which soon becomes chronic, and resists all methods of treatment.

11.—This state is always accompanied with a tendency to paralysis accompanied by singing in the ears and violent headache, symptoms which are attributable to defective nourishment and to the presence of fibrinous masses in the capillary vessels.

12.—There are often at this stage symptoms of bronchitis. The expectoration is thick, yellow, principally at night, and it is complicated with dyspnœa and palpitations.

13.—Diabetes and strumous affections often supervene on a diet exclusively saccharine or containing too much starch.

14.—The diarrhœa, characterised by colloid greenish stools, which attack children during the summer, depends on the abuse of saccharine substances and fruits, and the colloid masses are divided from the intestinal epithelium.

The Royal Irish Academy and the Dublin Scientific Societies.

As we anticipated, the societies of Dublin, though no doubt anxious to co-operate in any measure which would promote science or benefit the Academy, have not received the proposal which we detailed in our last with any great enthusiasm. We learn that the Geological Society have only accepted it in a very modified form. The Society is in a flourishing condition, is provided with a *locus* by the University of Dublin, and possesses a considerable fund in hand. It is not disposed, therefore, to merge its identity in the Academy ; but it will consent to hold its meetings and publish its transactions in connexion with the Academy, still retaining its funds and its separate entity. The Chemical Club discussed the proposal last week ; and though the members were indisposed to discourage, in any respect, the rejuvenation of the Academy, it was felt that the objects of the Club were not such as would fulfil the Academy's idea of a scientific section. The Club was started originally for the communication of knowledge in a sort of conversazione ; and it was considered that the reading and publication of essays would be *ultra crepidam.*

We anticipate that, despite these discouragements, an effort will be made by the Council of the Academy to establish the Sectional system ; and we conceive that it can do so with much less injury to its prestige, and perhaps as effectually as by the haphazard assimilation of all members of Dublin societies.

Burial Grounds and Sewage.

The last meeting of the Academy of Sciences of Paris was occupied by a representation from M. Dumas on the matters of great interest to the public health.

The first was relative to the enormous quantity of human remains contained in the soil on which great cities are built, by reason of the cemeteries which have hitherto existed, and are still to be found occasionally. According to an investigation by M. Freycinet, ii would appear that there are at least 100 millions of pounds weight of such *débris* in the soil of London.

The second observation treated of the sewage of Paris, the quantity of nitrogenous matter it contained, and its applicability to agricultural purposes. It would be necessary, said M. Dumas, to sink seven millions of francs every year, if we wished to render the same quantity of water as rich in nitrogen as the sewage is. How many more millions are lost in not utilising the sewage could hardly be stated. If he had thought that this question would come under the discussion of the Academy, he would have brought with him specimens of sewage, in order that he might show the Academy a simple and rapid manner by which its purification might be effected. It was sufficient to add to it a very small quantity of alum in order, at the end of five minutes, to produce a dense flocculent deposit, which carried down with it nearly all the nitrogenous matter, which was in suspension in the liquid. The supernatant fluid would be limpid, and so free from smell, that birds would drink it. With one centime of sulphate of alumina a cubic metre of sewage may be so purified.

Who'll Bid?

DEGREES.—Gentlemen desirous of obtaining degrees from foreign universities must state their qualifications, and apply for form, &c., to Dr. S., ——— street, London, N.

From a morning contemporary we clip the above ominous announcement. To anxious, yet not over-energetic title hunters, the reader will see it offers the usual advantages, at, of course, the usual rate per head, payable in advance!

The "Bermondsey Spec" having fallen through by reason of the *untimely* interference of the police authorities, this Packington Street Spec will yield to the brazen "Doctor S." ("Spec," if you will), and the diplomatic hucksters of whom he is the trumpet, a harvest, perhaps, if not as ample, sufficiently so to meet the pressing requirements of either home mendacity or foreign university mendicancy. That the police official sickle might be employed in the really ripe field of medical puff quackery and humbug, there is no doubt, but how to employ it is still the problem. This "Dr. Spec's" affair reveals to us the system in a rather chivalrous sort of light, and with a sprinkle in it of the philanthropy attributed by moralists to the wily spider when proffering to the semi-wary house-fly the advantages of a quiet home and fraternal fellowship. The system tells sometimes—rather, it pays, therefore sharks, be jubilant.

Dr. Moore and the Belfast General Hospital.

THE reproach against the social relations of medical men which has called down on our profession the many sneers and much ridicule, the contemptible and narrow-minded jealously between individuals—a feeling which if it exist in other professions, is certainly kept in commendable secrecy. We regret to observe a peculiarly humiliating display of this feeling in Belfast. The Board of Management of the General Hospital have been forced into an investigation of a charge which is thus recorded in the minute book. The treasurer stated to the Board certain charges made to him by Dr. James Moore in reference to an operation performed on Adam Martin, a patient who had died in this Hospital, reflecting upon the character of the medical gentlemen who conducted the operation, *and stating at the same time if he had been present the result would have been different.* The treasurer then reiterated circumstantially Dr. Moore's statements, and the injurious allegations he had made regarding the Hospital, which, the treasurer affirms, he was prepared, if necessary, to substantiate upon oath. Dr. Moore stated that the treasurer had entirely misunderstood him in the conversation referred to; that he had never intended to make any charge against Dr. Wm. MacCormac, or the Hospital; and that if any such had been made by him it was now withdrawn in the most unqualified manner. Dr. Moore also stated that he believed there were no grounds whatever for injurious imputations against the surgical practice of the Hospital. With so complete a repudiation of the statements attributed to him we are bound to assume that Dr. Moore's observations were misinterpreted. Nevertheless, it is most unfortunate that their general tone should be such as to convey to the mind of an unprejudiced listener so serious and unworthy a slight on Dr. MacComac, and to put Dr. Moore in the position of an abject disclaimer. After the fullest inquiry and investigation into every circumstance connected with the case, it was unanimously resolved—"That the Board of Management desire to record their full appreciation of the great skill, kindness, and attention of Dr. William MacCormac, the surgeon who operated, and also of Dr. Brown, who assisted at the operation performed in the case of the late Adam Martin, who died in the General Hospital of strangulated hernia, upon the 26th of February, 1869." We are unpleasantly reminded that we have been obliged some years ago to notice a similar attitude of Dr. Moore, in respect of his medical brethren in Belfast, and we are constrained to say that he is, in respect of his relation to them, either the most unfortunate or most injudicious of men.

Town Sewage.

MERTHYR Tydfil has fallen a victim to the same circumstances that have caused Cheltenham, Leamington, and some other towns so much expense. The Local Board having expended £30,000 on the drainage have had an injunction served to restrain them from polluting the river. Land cannot be had for irrigation, and after much anxious consideration another scheme has been adopted, viz., to continue the main sewer seven miles further down the valley, to a point four miles above Pontypridd, where it widens considerably. Here there is a large tract of common land suitable for the purposes of irrigation, and which may be acquired on easy terms. About 400 acres will be required for the effective disposal of all the sewage of the town, and the cost of continuing the main conduit to this land, and preparing it for the sewage is estimated at £20,000: but, on the other hand, it is calculated, from what has been done in other districts, that in the course of a short period the soil will have been so much improved by the application of sewage as to command good tenants at rents that will cover all the outlay, the land being admirably situated with regard to the centres of population.

Charing Cross Hospital.

THE above institution has entered on its fifty-first year of charitable usefulness. The annual dinner in aid of its funds was held in Willis's Rooms, on the 13th instant, the guests on the occasion numbering about 200.

During the evening it was stated that the expenditure in connection with the hospital for the year 1868 amounted to £7,423, and the reliable income about £3,000, which statement exhibited a balance on the wrong side of over £4,000.

No more noble proof can be adduced of the high estimation in which the charitable and philanthropic hold Charing Cross hospital, than the telling fact, that the subscriptions amounted during the evening to the magnificent sum of £2,500, which sum includes the Queen's donation of £50.

Staffordshire Asylum.

THE fourth annual report of the Staffordshire Asylum has reached our hands. It has been carefully and studiously prepared, and offers to the medical reader invaluable tables of statistics, unburthened by irrevelant matter, terse, concise, yet forcible, nevertheless.

Spinal Injuries.

We lately drew attention to the differences of opinion so often exhibited in the witness-box by members of our profession. The trial of which we speak, and which ended in a verdict for £4,000 damages, is likely enough to give rise to further litigation. Another trial has ended in a verdict for damages of nearly as much. This latter case was *not* a railway one, but arose from the plaintiff having met with an accident by falling down an open communication with the hold of a ship on which he was passenger. Railways have been blamed for peculiar effects by some, whilst others have contended for quite different views. The reader cannot fail to be interested in the following extract from the evidence as reported in the *Times* respecting the case to which we have alluded.

> "The evidence of various medical men in India was read, and Mr. Erischen was called as a witness. He said he saw the plaintiff first on the 17th of last month, just after his return from India; he was suffering from the effects of two distinct injuries—dislocation of the right shoulder and disturbance of the nervous system about the head and spine. The right shoulder was painful, and the movements were difficult. The arm could be moved forwards, and in an underhanded manner, but not backwards, nor raised from the shoulder—or, at least, only to a very limited extent. In addition to the dislocation, there must have been some other injury, for there were various symptoms referable to irritation of the brain, as, for instance, frightful dreams, loss of memory, and irritability of temper. On examining the spine he found it tender over two of the vertebræ and in the loin, and bending the spine increased the pain. The plaintiff complained also of uneasy sensations in the legs, a prickling numbness, and startings. He rather dragged the right leg, the muscles of which were less sensitive to the electric current than was usual or natural. There were also other symptoms, the usual effects of irritation of the spinal nerve. The witness concluded that the present condition of the shoulder was in consequence of the dislocation described, and he attributed the other symptoms to the unusual severity of the injury and laceration of the muscles. The plaintiff might, perhaps, have been pulled out by the dislocated arm, or might have fallen upon the shoulder itself. The witness thought he would recover the underhanded movements; for instance, he might be able to write; and the nervous symptoms might disappear, but he would never be able to raise his arm for any useful purpose."

The Dangers of Metal Stoves.

General Morri has just made a report to the Paris Academy of Sciences, in the name of the commission appointed to inquire into the alleged insalubrity of metal stoves. The result of numerous experiments instituted by the commission is that the use of metal stoves is dangerous to health. Contrary to the opinion of Dr. Caret, it is found that wrought iron stoves are, to a certain extent, objectionable, but not nearly so much so as those of cast metals. Both are found to disengage considerable quantities of oxides of carbon. The heat too quickly desiccates the confined atmosphere of rooms, and may, moreover, decompose the carbonic acid of the air. These dangers commence at a dull red heat, and it, therefore, seems that those who continue to use metal stoves should invariably have them fitted wih fire brick so as to prevent their becoming heated to redness.

By the will of the late Mrs. Celia M. Boulton, of St. John's Wood—Westminster, St. George's, St. Mary's, Middlesex, Charing Cross, and the Cancer Hospitals, each receive a legacy of £200, free from income tax. The Royal Hospital for Incurables also receives a like amount.

In the Lynn poisoning case, the jury returned a verdict that deceased died from diseases from which he had long been suffering, but that his death was hastened by strychnine given by his wife, she being of unsound mind. The viscera gave no traces of the poison on chemical investigation.

The Middlesex Hospital Home for Nursing—a building in connection with, and adjoining the, Middlesex Hospital—was opened on Thursday last by the Princess of Teck. The institution is to accommodate fifty women as probationers, who after having received a complete education in nursing in the wards, may become either permanent nurses on the staff of the hospital, or be available for the exigencies of private families. Lady Louisa Ponsonby and Miss Burdett Coutts were among the ladies who attended the ceremony.

On the 10th inst., at the comparatively early age of 48, died Dr. McCormick, a highly respected practitioner of Bayswater, and who will be a great loss in that locality, especially amongst the poor, who always found in him a ready friend.

In 1847 he contributed a paper on "Epidemic Fever and Dysentery" to the Medical Press, and has since communicated some practical notes to other medical journals. He was M.D. and L.R.C.S. Edin., L.S.A. Lond., and L.M. Dub.

◆

LYING-IN HOSPITALS AND EXTERN MATERNITIES.

The debate of the Dublin Obstetrical Society on Dr. Evory Kennedy's paper, which we reported last week, was renewed with great vigour and much interest to the profession last Saturday. The President and Vice-President of the College of Physicians were present, and the room was crowded at all parts. The debate was opened by Dr. McClintock, who, at great length and with much power and eloquence, treated the subject. His speech occupied almost the entire evening, and was, without doubt, *the* speech of the occasion.

Dr. McClintock commenced his observations by expressing his opinion that, without doubt, metria is a zymotic disease; but in enunciating this fact it was necessary to distinguish between cases of simple post-partum peritonitis, which had no such character, and the true blood poison of metria, which resembled uterine phlebitis more than any other disease. He was of opinion that puerperal fever and erysipelas were mutually convertible, the one into the other, and had one and the same contagion. He was not new in this idea, for Putot and Dr. Douglas had expressed the same opinion, and Mr. Simon had said that a surgeon in attendance on erysipelas might communicate metria. This analogy had been followed up by Cruveilhier's comparison of a lately delivered woman with a newly operated patient, and by Mr. Dease's parallel between the pathological conditions after metria and after bladder operations.

He (Dr. McClintock) and Dr. Hardy had always held the strongest opinion that metria was so highly communicable that no man would be justified in neglecting the smallest precaution against its transmission, but Dr. Meigs had met this statement by an "utter rejection and denial." It seemed to him that the length of the period of incubation of zymotics was an important argument against Dr. Kennedy's argument, for there was no analogy whatever for a disease communicated epidemically with the short interval which was known to precede many cases of metria. Aickin placed the incubative period of metria at ten to fourteen days, and thus it would seem that puerperal fever, which often appeared in a few hours, must be rather by inoculation of virus than by infection.

He (Dr. McClintock) quite agreed with Dr. Kennedy in his disapproval of lying-in wards in general hospitals, and he would go further and say that if midwifery students abstained from dissections, and obstetric practitioners from *post-mortem* investigations, the disease would be much less frequent. "The man who devotes himself to obstetrics should abjure pathological anatomy."

He thought, then, that in respect of its contagiousness Dr. Kennedy had made out a strong case, but that he had failed to show that the disease was proportionate to the number of women in hospital. How could this theory be maintained in face of the statistics? He found that, in 1842-43-44, the deaths amounted to 1 in 214; in 1850 to '53, to 1 in 565; while from 1829 to '33 on a yearly average of 2,150 cases, or a total of 10,785 deliveries, there was *not one single death*, while within the last fifteen years, when the admissions were not one-half, the mortality was doubled. Furthermore, it appeared that in the first three years of Dr. Labatt's Mastership there were 10,248, and yet the death-rate was only 1 in 180. Surely this disproved any proportion between crowding and mortality. And even in country hospitals the theory was not carried out, for he found that, while New Ross Hospital only admitted thirty patients a year, Waterford Hospital, with three times the number, had a less mortality. And the fact of an hospital being small did not seem to protect it in the least, for we had the instances of the South Eastern Hospital, admitting only 350 patients a year, with a mortality of 1 in 69; and Kingstown, admitting only 90, with a mortality of 1 in 114 from metria alone.

Dr. McClintock greatly distrusted the statistics adduced by Dr. Kennedy, for there were many differences between the hospitals compared which invalidates the conclusions; for instance, some hospitals admitted only certain classes, while others were obliged to take in all comers, and seduced women resorted to them in much greater numbers. His experience instanced this fact in a very forcible way. During his mastership of the Rotundo, there were 126 women admitted who were *known* to be unmarried, of whom the enormous proportion of 46 died—a mortality which cannot fail seriously to influence the statistics. Moreover, the very numerous deaths which occur during, but not in consequence of, the puerperal state were not charged against the obstetric mortality anywhere except in lying-in hospitals; elsewhere they went to swell the general death-rate. In lying-in hospitals they were debited to the midwifery mortality. Dr. McClintock produced a table, or tabular statement of the mortality in private practice, under some of the most reliable practitioners. It showed that the mortality in childbirth from *non-puerperal* disease was 27 per cent. of the whole mortality, or more than one-fourth. If these deaths were eliminated from the extern returns, a mortality of 1 in 200 would be 1 in 145; and if the omissions from defective registration were allowed for, the proportion would become 1 in 129. Moreover, it appeared that in private practice in Ireland in 16,106 cases the deaths were 1 in 134, and this amongst patients derived from the superior classes.

Dr. McClintock then proceeded at length to corroborate these statements from the registration statistics, and declared as the result of his calculations, that the death-rate of women in their own homes was 131⅓—a much closer approximation to the mortality in lying-in hospitals than Dr. Kennedy had represented.

Dr. Denham, in continuing the debate, pronounced the statistics of out-door delivery absolutely unreliable, because the cases were seldom seen more than once after delivery, and were set down as recoveries when, in fact, they might be deaths. If small hospitals were to form a just comparison, they should be in cities and not in country atmospheres. He thought the great mortality of the last fifteen years might be easily accounted for—firstly, by a very unwonted prevalence of zymotics in Dublin in that time. On this subject he quoted the opinion of Dr. Stokes. Secondly, because the instant a death occurred in hospital it changed the class of cases admitted, and thereby increased the mortality by keeping away the better class of patients.

Dr. Denham read two letters—one from Dr. Martin, of Portland, acknowledging the frequency of puerperal fever in his district, and the other from Dr. Johnson, of Kilkenny, to the effect that for twenty years he had not been aware of a case in his locality. Dr. Denham said these letters proved the capriciousness of the disease even in country districts.

At the conclusion of Dr. Denham's remarks, the debate was adjourned. It will be resumed on Saturday evening next by Dr. Sawyer.

PRESENTATION TO DR. A. C. CHALMERS, THORNHILL.

A correspondent forwards us the following from a local contemporary :—

Dr. Chalmers who has for many years practised his profession with great acceptability over a wide district, of which Thornhill is the centre, being about to remove from that locality to Sheffield in England, his many attached friends determined to present to him some lasting testimony of their gratitude and esteem. The time being limited the ceremony took place in the Buccleuch Hotel, Thornhill, on the morning of the 28th ultimo. Dr. Russell in the chair.

Before proceeding to present the testimonial, the Rev. Mr. Murray, minister of the parish, who was chosen by the committee to do so, after stating that he regretted the duty had not fallen on some other individual better qualified, addressing Dr. Chalmers said :—It is now seventeen years and upwards since you came to the Upper Vale of Nith highly recommended by eminent men, professors of the School and Universities of which you are a distinguished alumnus and graduate, and also by others who perhaps less known to fame, were equally well qualified to judge of your professional ability and attainments, and it is almost a work of supererogation to tell the meeting now assembled, how nobly you have responded to the recommendations, now referred to, or how well you have realised the high expectation which at the outset of your career amongst us, we were led to form of you. You have in all respects done your duty admirably, and to the entire satisfaction of all classes of the community. In your general practice you have at all times manifested much skill and judgment, and at particular times, and in more trying cases you have evinced a degree of reliance on your own professional resources, which men of more timid and less firm minds cannot well understand or appreciate. You have proved yourself in all respects a master in your profession and worthy of all trust and confidence. It cannot then, I am sure, be a matter of surprise that the regret generally felt at the prospect of your departure should have taken the shape it has this day done in the handsome memorial now before us. To the poor especially, your departure will be a severe loss, and your name by them will be long held in grateful remembrance. These things being so, it may be naturally asked why does Dr. Chalmers leave? Or why should he wish to transfer his services to another and distant part of the kingdom? The answer is easy and ready. Dr. Chalmers never bargained to remain here for life, and he has talents and energy for a far more important field, and such a place as Sheffield offers many attractions which no mere provincial district affords to a man of his reflecting and enquiring mind. The population of Sheffield is great, its wealth is great, and then every branch of science and of art meets with due attention. New discoveries, whether in medicine or aught else are without hesitation considered and tested, and every encouragement given to genius and exertion. In such a place talent of every kind has full scope, and merit receives its due reward. In one word I augur well of the step you are about to take, and I believe that a bright future is in store for you. You are still in the prime and vigour of your life, health and strength are your portion, and by God's blessing on your labours a man of your enthusiasm and perseverance must succeed. Mr. Murray then presented Dr. Chalmers with a chronometer of much value, and added, at the request of the subscribers, that a much larger sum than the cost of the timepiece was still on hand unappropriated. That Dr. Chalmer's hurried departure had not afforded time to dispose of that sum satisfactorily, but that other souvenirs of his labours would in due time follow him to his home in Sheffield.

Dr. Chalmers replied as follows :—Mr. Murray and gentlemen, I can assure you it is no affectation of language when I tell you that I find it impossible adequately to express how much I feel your kindness in presenting me with such a very handsome and very valuable gift, and the kind wishes with which you have accompanied it. At all times a very bad speaker your great kindness and my own unworthiness of such a distinction as you have been pleased to accord me paralyses my utterance so that I can only, and that in very few words, say how much I thank you, not only for this but for the unwearied kindness and courtesy I have had extended to me for the seventeen years spent so pleasantly amongst you, and which go where I will can never be forgotten. That love is now in a degree broken, but believe me from the kindly feelings so able expressed by Mr. Murray, and so cordially responded to by so many of my friends now around me, it can never be altogether severed, and although painful to say good bye, I hope the time may come when we may meet again and renew to a certain extent what has always been to me pleasant intercourse ; and sincerely do I hope you will never have cause to regret the proceedings of this morning, whilst it will be my earnest and constant endeavour to give none. Be assured of this, gentlemen, I feel much more than I can possibly express on this occasion. You will, therefore, I feel certain, kindly excuse the brevity of my remarks and not take it as a gauge of my gratitude for your very great kindness. Again, thanking you now present, and all my other friends who have so highly honoured me, I shall now most gratefully bid you good bye.

◆

Transactions of Societies.

ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

5th May, 1869.

Deputy Inspector General C. A. Gordon, C.B., in the Chair

TWO CASES OF CEREBRO-SPINAL FEVER,

which have lately occurred among the troops in garrison, were brought before the Society :—

The first, described by Assistant Surgeon J. Ross Murray, R.A., was that of a driver, æt. eighteen, with five months' service; of temperate habits, and well conducted. He was admitted to hospital on the 15th April, 1869, complaining of lassitude; anxiety at præcordia ; and slight febrile symptoms. An eruption of a petechial character having appeared on the legs an hour or two after admission to his battery hospital, as a precaution, he was removed the same afternoon to the infection ward at Portsmouth. He stated that on the day previous, he had been drinking with a comrade (since dead from the same disease), in a public house, in a low and dirty part of Portsmouth.

On the morning of the 16th, when seen for the first time by Dr. Murray, to whose care he was transferred, he had passed a restless night from severe and continual vomiting of dark green bilious matter, and frequent purging, he was slightly feverish ; a diaphoretic mixture was now prescribed.

On the 17th, symptoms had developed, which left no doubt as to the nature of the case. Delirium had set in, with intervals, during which he was very apathetic, but answered questions rationally. There was now well marked retraction of the head (opisthotonos), great pain in the muscles of the back, extending down to the lumbar region, and muscular debility of the lower extremities, almost amounting to paralysis. Pulse 84, Temperature in axillæ, 100, skin moderately cool and moist. Quinine, grs. iv., calomel, grs. ij, opium, grs. ¼, were now ordered every second hour ; ice to be applied to the head, a blister to the nape of the neck, and dry cupping along the spine. At evening visit, the delirium was found to have increased, the retraction of the head was more marked, and the pulse had risen to 120, these was conjunctivitis of the eight eye. Temperature in axillæ 101°, respirations, 23.

On the 18th he was semi-comatose, the right cornea had become quite opaque, the eruption had commenced to fade, but the retraction of the head was still well marked. Some urine, obtained for examination, showed a sp. gr. 1006, was slightly deficient in chlorides, but gave no trace of albumen. He got gradually worse towards evening, and was evidentaly sinking. Pulse, 92, respirations, 23, temperature. 100°.

On the morning of the 19th, complete coma had set in, the pulse was very rapid (152), small and thready, temperature 105, respirations, 41 ; tongue dry, brown and glazed. In addition to the petechiæ in the legs, a bruised appearance of the skin of lower extremities showed itself. He died at 3.40 p.m. on the 19th, the fifth day.

On *post-mortem* examination twenty hours after death, the spinal sub-arachnoid space was found filled with a layer of greenish yellow lymph, which closed the spinal cord from the medulla downwards, the substance of the cord itself appeared normal to the naked eye. On reflecting the dura mater cerebri, an extensive deposit of greenish yellow colour, closely resembling pus as seen through the arachnoid, but proving, when cut into, to be firm lymph, following closely the vessels of the pia mater, which were themselves much congested with fluid blood. The lateral ventricles were distended with serum, and the crura pons varolii, and optic commissure were covered anteriorly by a thick greenish gelatinous looking lymph, which extended along the right optic nerve for about a third of an inch. A layer of lymph coated the anterior surface of the iris of the right eye. A water colour drawing by Dr. Lamprey, 67th Regiment, was exhibited showing very exactly the appearance of the cerebral lobes, when the dura mater was reflected.

The second case read to the Society, by Dr. Park, Royal Artillery, was that of a driver of the 11th brigade, a comrade of the former man, æt. twenty-nine, service nine years, whose habits were temperate, and conduct good. He had been absent in Portsmouth for three days, the greater part of which was spent in his company at the same public house. He returned to Hilsea on the 16th April, and was punished for absence, by seven days' confinement to barracks. He reported sick early on the morning of the 20th April. As he was unable to attend stables at half-past-five in the morning, and complained of general feeling of malaise, with pain in the lower extremities, slight sore throat, pain at præcordia, and extreme restlessness. His symptoms resembled those of the cold stage of ague, with marked "cutis anserina," eyes suffused, quickened pulse, and the tongue coated with a whitish fur. A cathartic dose of infusion of senna and sulphate of magnesia was given, and the throat was swabbed with a solution of nitrate of silver. Two hours afterwards, at 9 a.m., there was very great exhaustion, pulse 130, small, and wiry, he complained of coldness of lower extremities, and great frontal headache, there was no eruption. At 3 p.m. he was still more prostrated, and was now covered with large black patches of ecchymosis, the general hue of the skin being a dusky yellow. He was perfectly conscious and rational until about twenty minutes before his death, which took place at 5 20 p.m. rather suddenly. Just before death he ejected some bloody mucous from the mouth and nose. At 9 a.m., five grs. of calomel were prescribed, and ordered to be followed by five grains of quinine, every two hours. Beef tea and brandy were given.

Post-mortem examination forty-two hours after death, showed the membrane of the brain and spinal cord intensely congested, and the sinuses enormously distended with dark fluid blood. There was considerable effusion into the sub-arachnoid space, and the cerebal ventricles contained an ounce of pinkish serum. The brain and upper part of the spinal cord showed numerous red points on section. The lungs were gorged with blood, the right side of the heart contained fluid blood, while the left was empty. The blood was everywhere fluid, of a dark colour, and apparently disorganised, it continued to ooze out for some hours after the *post-mortem* was completed.

The Honorary Secretary read a paper by Assistant Surgeon Wales, R.H.A. "On a Peculiar Form of Athritis."

◆

SURGICAL SOCIETY OF IRELAND.

April 16, 1869.

George H. Porter, Esq., M.D., President of the College, in the chair.

The Society met in the Albert Hall, Royal College of Surgeons. The following members were present :—

Messrs. C. Moore, M.D. ; G. Montgomery, F. T. Porter, M.D. ;

Murdock, M.D.; H. Stewart, G. Buchanan, H. Coulton, E. D. Mapother, W. T. Stoker, Charles Benson, J. H. Benson, W. Colles, R. Bookey, R. Macnamara, Vice-President; J. H. Wharton, P. Shannon, D. B. Hewitt, T. Darby, J. Leech, C. Nixon, J. G. Beatty, M. H. Stapleton, W. Stokes, junior; F. S. McDowell, J. Tufnell, and B. Wills Richardson.

CHRONIC ULCER OF THE STOMACH—ADHESION TO THE PANCREAS—DESTRUCTION OF ALL THE COATS OF THE STOMACH—SLIGHT EROSION OF THE PANCREAS—DEATH FROM TUBERCULOSIS.

Dr. Hewitt exhibited the stomach, lungs, liver, and small intestine of a girl, aged twenty-three, who had died of exhaustion, induced by rapidly developed tuberculosis, coming on nearly six years subsequent to the first appearance of symptoms which were referable to gastric ulcer. The ulcer was on the posterior surface of the stomach. It had led to such constriction as to give rise to the hour-glass appearance, and, though from this change of shape it was not easy to say positively, was probably nearer to the concave margin. The ulcer in outline was somewhat like a longitudinal section of a pear; its margins were greatly thickened, and the infiltration extended to a considerable distance from its edge. The base of the ulcer was formed by the anterior surface of the pancreas, which had undergone slight erosion. The edges of the ulcer were rounded off, and the handle of the scalpel could be inserted between the edge and the pancreas. Firm adhesions existed external to the margin of the ulcer, between the stomach and pancreas. The constricted portion of the stomach admitted two fingers readily. There was not the slightest trace of any other ulcer or cicatrix in the stomach. The liver was enlarged; its convex margin was adherent to the cartilages of the ribs by long transparent bands, in which small blood-vessels could be detected. Several small, yellow, cheesy masses, the size of a coriander seed, could be seen shining through the peritoneum on the surface of the liver. Where the anterior margin of the left lobe came in contact with the thickened and constricted surface of the stomach, there appeared to exist, to the extent of a square inch, a white fibroid infiltration of the liver, which, on section, was found to extend into the substance of the organ, and to exist chiefly around the vessels in the portal canals—in fact, it was an example of that limited cirrhotic inflammation of the liver noticed by Habershon in cases of ulcer of the stomach where the liver came in contact with the site of inflammatory thickening around the ulcer. The liver was otherwise tolerably healthy.

Scattered under the peritoneum in all directions, numerous small granulations of yellow tubercle were visible, and similar small masses were situated in the site of the solitary glands in the small intestine. The last few inches of the ileum was one mass of yellow cheesy tubercular infiltration of the glands of Peyer, and for an inch or two above the ileo-cœcal valve the irregular ulceration, with raised and irregular adhesions, so characteristic of tubercular disease, was but too apparent. Several small round and some oval ulcers, with raised edges, existed in the cæcum; this ulceration had not extended to any depth. The right pleural surfaces were, to a great extent, agglutinated by thick organised adhesions, and between the meshes of the adhesions there was a considerable amount of yellow sero-purulent fluid. The right lung was solid throughout; a section displayed the deposition of tubercular granulations throughout its entire extent, and numerous cavities of various sizes and very irregular shapes, with rugged walls, were distributed throughout the lung; one larger than the others occupied the inferior and anterior part of the superior lobe.

The left lung contained a great many masses of tubercle scattered throughout its substance, but there were no cavities. The apex, anterior margin, and internal surface of this lung were very emphysematous.

Dr. Hewitt then gave the clinical details of the case, for much of which, he said, he was indebted to Dr. J. H. Benson, under whose care the girl had been for a considerable period. She was admitted into the City of Dublin Hospital, on October 28, 1867, under the care of Dr. Benson; she was then twenty-one years of age, and had suffered from pain in her stomach and disinclination for food for more than four years. She said that at first the pain was aggravated by food, and relieved by vomiting. She had menstruated regularly up to a year before her admission, and she stated that she had vomited some "black stuff" about six months before. The pain in the stomach was not precisely located by the patient, nor did she refer its point of greatest intensity always to the same region of the stomach; it was much worse after food had been taken, although she never referred the increase of pain to the use of food, and complained much more of it at night and during the early morning than throughout the day. She complained of a beating in the epigastrium, but neither tumour nor distensile pulsation could be detected. On auscultation, a distinct bruit in the aorta was audible.

The stethoscopic examination always gave great pain, so that it was omitted for a long time. The bowels were generally confined; the tongue was natural; the appetite was not much impaired. The vomiting was very frequent; it did not come on soon after food, and was most frequent at night. The vomited matters were usually dark green, abundant, acid, and contained a good deal of mucus. Under treatment, the pulsation and bruit in the aorta gradually disappeared.

Dr. Benson's first notion respecting the case was, that it was an aneurism of the abdominal aorta, but this idea was soon abandoned, and that of gastric ulcer entertained; and Prof. Benson at that time thought the balance of evidence was in favour of that view of the case. Both lungs and heart were examined frequently, but no lesion could be detected.

When the patient came under my care, the symptoms had undergone considerable modification; all pulsation, bruit, and epigastric tenderness had disappeared. Severe pain continued, but it was complained of in a great many situations, one day in the lower part of the back, another between the shoulders, while on a third occasion she would refer it to the epigastrium and right or left hypochondrium. She had a very quick pulse, and complained a good deal of palpitations.

The exacerbations of pain and vomiting came on at night, while during the day she often got out of bed and went about the wards, and even secured the remains of chops and other food which some of the patients could not use; these she ate from time to time, and she always opposed the restriction to fluid food and nutritive enemata.

These circumstances, with the fact that evidence of hæmorrhage was slender, and only founded on the statement of the patient respecting the occurrence of what she had learned to call "coffee-ground" vomiting, and the long period which had elapsed since the advent of the pain without any symptom of perforation and with no excessive degree of emaciation, and, above all, the existence of a very fair amount of appetite, and that for food requiring considerable digestive power, made him doubt the existence of an ulcer. After pursuing a sedative line of treatment for some time with but very partial relief, and having blistered the epigastrium more than once to check the vomiting, he determined to stop all solid food, and, at the same time, to give small doses of arsenic by the mouth and nutritive enemata. After a very few doses of the Fowler's solution, she experienced great relief from the pain, and in twenty days she was so much improved that she was allowed a cautious return to solid food of a very bland nature. She left the hospital, and rapidly recovered her appetite and strength, and after three months she had regained her flesh so much that you could hardly recognise her.

On the 6th of January, 1869, she was admitted a second time, under the care of Dr. Benson, complaining of a return of the pain of much less severity than on the former occasion; there was no vomiting, but she had again lost flesh to a great extent. The lungs were examined, but nothing wrong could be detected. Dr. Benson, learning that she had derived benefit from the Fowler's solution, prescribed it for her, but on every occasion it aggravated her pain. About three or four weeks before her death, she complained of cough for the first time; this was accompanied by an abundant muco-purulent expectoration, and on stethoscopic examination there was detected *bruit de pot fele*, cavernous respiration, pectoriloquy, and gurgling, about half an inch below the right clavicle. The progress of the case to a fatal issue was rapid, but it is remarkable that there was no purging, notwithstanding the ulceration in the intestine.

Dr. Hewitt drew attention to the form of ulcer in this case, which, though common at a more advanced age, was unusual in one so young. He thought the case interesting, as proving the possibility of a change in the symptoms and of temporary recovery, with a return of nutritive power sufficient to cause the disappearance of loss of flesh. This girl had looked ruddy and fat for some months. It also threw light on the connection between gastric ulcer and those complications which so often exist in amenorrhœa. He believed they were both alike, the result of that deterioration in the blood caused by the imperfect nutrition necessitated by the ulceration. This was a case in which tubercle was developed by mal-nutrition, for none of the girl's relatives are consumptive.

He thought the case proved the great value of rest to the stomach in the treatment, and he drew attention to the curious fact that arsenic, instead of aggravating the symptoms at a certain stage seemed to give decided relief, while later on it only served to increase the pain. This difference might be accounted for, he thought, by some such difference as was often found in external ulcers, which, at a certain stage, bore stimulation very badly, and at another well.

Dr. Tufnell read a paper on a case of

FEMORAL ANEURISM, TREATED PRIMARILY BY COMPRESSION, AND SECONDARILY BY THE LIGATURE.

In this case, Mr. President, which, with your permission, I beg to lay before the Society this evening, death ensued from pyæmia, the 21st day after the operation.

It is interesting to those who are advocates for the treatment of aneurism by compression as showing that the failure of cure in each instance was owing to constitutional causes, and that whilst compression did not succeed, the ligature would equally have failed, as death from secondary hæmorrhage must inevitably have ensued had life been prolonged until the continuity of the artery was severed by ulceration.

The patient in this instance was a gentleman, fifty years of age, of very steady habits, even temperament, and well regulated mind, just the very reverse of an individual in whom you might anticipate this disease. His pursuits were literary, and the only exertion to which he could possibly attribute the occurrence of the aneurism was working occasionally at a forcing pump.

In the latter part of July of 1868, he complained of uneasiness extending along the inner side of the right thigh, more particularly when he lay down in bed. Upon the 15th August, when examining the limb with a view to ascertain the cause of this pain, he discovered a small swelling below the groin, which he regarded as a sympathetic enlargement of one of the inguinal glands. He accordingly, treated it as of no consequence continuing his ordinary occupation. As the month wore on however, he found the swelling to be increasing in size and becoming soft, with a marked pulsation in it. He now showed the tumour to Dr. Lawlors, of Tralee, who in consultation with Dr. Crimp, at once pronounced it to be aneurism of the femoral artery, and recommended that the treatment by compression should be adopted. The patient was ordered to bed until Carte's pelvic compressor could be procured from Dublin.

This was applied for the first time upon the 4th of September last, and worn for a few hours each day during six weeks, partially cutting off the flow of blood, but not entirely arresting the circulation. The general health of the patient during this time was good, he required no medicine of any kind and was allowed to get out of bed for all necessary purposes, at the end of six weeks he felt so much improved that he was permitted to get up and move cautiously about the room, and a fortnight later to walk daily to his club, a distance of about a quarter of a mile from where he lived. The pulsation at this time although greatly diminished, had, however, never altogether ceased. The tumour again began to enlarge, and the progress of the case becoming tedious, Dr. Lawlors brought this gentleman up to Dublin for consultation, and early in December he was seen by Dr. McDonnel and myself. The aneurism was now about the size of a large lemon, and somewhat of the same shape, with all the ordinary symptoms present. Complete occlusion of the artery not having been previously carried out for any continuous length of time, it was recommended that he should be placed under the influence of narcotics, or anæsthesia, and the circulation completely shut off from the sac for several successive hours. This upon his return home was attempted by the aid of opium, friends sitting up to see that the compressor did not slip off the vessel. Pressure was borne for eight hours consecutively the first night, three full sleeping draughts having been taken. Similar treatment was adopted the succeeding night, and upon some other occasions, but, all failing to produce consolidation of the contents of the aneurism, instrumental compression was given up, and he came again to town, arriving in Dublin upon the 25th of January of the present year. During this interval the aneurism had considerably increased in size, although the most perfect quietude had been maintained.

It now measured (including the girth of the thigh) over the centre of the tumour, twenty-three and a half inches, or about two inches more than the circumference of the opposite limb at its corresponding part; the thigh in the centre being about one inch larger than the other, but the calf of the leg of the same size. The aneurism was oval, situated in the line of the femoral artery, and filling the whole of the adductor space, being seven inches in length from above downwards, and six inches in transverse diameter. It encroached somewhat upon Poupart's ligament. The sac was perfect, but thin upon the inner side.

Pulsation was completely and easily controlled by pressure of the finger upon the artery at the pubis, the passage of the blood giving a peculiar whirring sensation or jar to the finger when laid upon the vessel. The bruit in the aneurism was a soft single souffle. The pulse 98 and regular. No disease could be detected by the stethoscope either in the heart or the great vessels. The functions of the bowels and kidneys were regularly discharged, and the tongue perfectly clean. There was nothing to indicate a departure from ordinary good general health, excepting a more than usual pallor of the countenance and skin, which might be accounted for by long confinement to bed and one room with restricted diet, and the medicine employed to reduce circulation and favour coagulation of the contents of the sac. There was no œdema whatever of either extremity. The popliteal artery beat freely, but neither the anterior or the posterior tibials could be felt.

It was now decided to employ digital compression for twenty-four hours *continuously*, by means of a relay of assistants, and a number of gentlemen having volunteered to relieve one another every half hour during the day and night, complete occlusion was commenced on Sunday morning the 31st of January, at eleven o'clock, by Mr. Browne, Mr. Croly, Mr. O'Sullivan, Mr. Thompson, Mr. Clendinnen, Mr. Bradley, Mr. Morris, Mr. Bloomer, Mr. Widdup, Mr. Moriarity, Mr. Townshend, Mr. Negan, Mr. Stokes, and Mr. Frile, many of these gentlemen being fellow-countymen of the patient. And I here would avail myself of the opportunityof saying that I never saw men stick to their work with such a determination to succeed, or subsequently after the ligature had been applied remain night and day in general close attendance, prompted solely by kindness of disposition, and a generous interest in the welfare of the patient, of whom I can only say that to know him was sufficient to create sympathy and engender friendship. I must apologise for wandering from my subject, but I feel that I should not be acting rightly towards those gentlemen were I to pass over in silence their devotion to the case.

Opiates in the form of black drops were given at intervals during the twenty-four hours, and during the period hardly a jet of blood was permitted directly to enter the sac. The period of pressure exercised by each volunteer being thirty minutes at a time, and the pressure maintained steadily during the shifting of the relay.

Towards nightfall the heart's action became rapid, and the pulse jerking from irritation, consequently upon the continuous pressure, but the effects of opium restrained this in a great measure. On the succeeding day, upon discontinuance of compression the only change perceptible in the aneurism was that the pulsation seemed to be less and the bruit diminished. The patient at once fell asleep, and slept almost continuously throughout the day. In the evening both pulsation and bruit had regained their former force.

Upon the 4th February, compression was again resorted to by means of Carte's pelvic instrument for a portion of the day, and digital pressure in the intervals applied by some of the gentlemen who came in turns and relieved one another so as to make in the aggregate a considerably prolonged arrest of pulsation of the tumour.

Upon the 5th February, the aneurism was somewhat flattened. Upon the 6th, the patient became restless, and at night dreamed horribly. Becoming alarmed, he struggled violently and straightened his leg with force. The following morning there was an increase in the size of the tumour, and a louder bruit. The leg was now slung up in a cradle of linen suspended from the railings of the bed, the thigh being placed upon the pelvis at such an angle as to reduce the circulation in the sac to almost nil.

Upon the 8th, this flexion was discontinued as it seemed to press the contents of the sac too much towards the front of the tumour, thereby altering its shape into a conoid form, and less forcible flexion had no influence in reducing the current of blood.

Upon the 9th, the aneurism was somewhat painful, and ice in a spinal ice bag was therefore applied upon its surface, and continued. Digital compression being used at intervals.

Upon the 10th February, Signoroni's tourniquet was applied upon the iliac artery, but its pressure caused intense pain, and after an hour it had to be removed.

It was reapplied upon the 11th, a large pad, formed of cotton wadding, enveloped in chamois leather, being laid over the artery and between the tourniquet pad and the skin. This permitted of its somewhat extended use, but still it could not be long endured. Its employment was, however, succeeded by the burning pain in the tumour, which has so often preceded cure. This pain came on at midnight, lasting until 2.30 a.m., when it lulled, and the patient slept, the pain returning upon his awaking, and continuing for two hours more. In the hope of producing consolidation Signoroni's touniquet was again employed the succeeding day, and applied for four hours consecutively, ether spray being douched freely over the aneurism. Digital compression was also used at intervals. Upon the 12th, the tumour had become somewhat larger, and at night there was a renewal of the burning, extending between the tumour and the knee, and prevailing to such an extent as in the patient's own words "*to rage fearfully.*" This lasted for the space of an hour and twenty minutes, when Mr. Neligan, who arrived during this time, at once put on strong pressure. This relieved the pain, which gradually died out. Next morning pulsation in popliteal artery was found to have ceased, but the aneurism itself beat as before, and was moreover somewhat discoloured upon the surface. I now resolved to allow the patient a day or two rest, and then to give him one more chance of consolidation of the contents of the aneurism by total occlusion of the vessel by digital compression, continued for twenty four-hours, and employed as before, the pressure of the finger upon the artery being but little heeded or complained of. Upon visiting him, however, upon the 18th, the day I proposed so doing I found that the aneurism had increased during the night, and I resolved therefore to tie the external iliac artery at once as the tumour now measured twenty-five inches in circumference, or an increase of an inch and half since arriving in town.

The operation was performed at one p.m., the incision being extended upwards and outwards for some inches in order to permit of the vessel being tied as far as possible above the site of the long continued compression, and also preparatory to further extension upwards, in the event of the external iliac artery being found, upon exposure, to be diseased, and the common iliac therefore requiring to be secured. No undue difficulty however, was experienced, and the artery when tied (about its centre) was found to be perfectly sound. A very considerable amount of yellow fat presented itself, and the vessel lay at a much greater depth than, from the appearance of the patient, might have been anticipated. The ligature employed was one of green hemp, well waxed, and the aneurism needle of the common kind. Upon tightening the ligature all pulsation ceased.

Brandy was given prior to the use of the chloroform, which was administered to full effect, thereby preventing any struggling upon the part of the patient—a most important point to be attended to in ligaturing either of the arteries of the abdomen, as obviating the forcing forward of the intestines and their protrusion into the wound, thereby obscuring the operator's sight. Towards evening delirium set in; the pulse rose to 126, and the patient complained of heat in the ligatured extremity. Thirty minims of black drop were given at first, succeeded by a second dose of twenty drops more; Wenham Lake ice and good claret and water were ordered to allay thirst. Upon the 19th, he was free from pain, tranquil and clear, having rested well under the influence of the opium, and awakening without any headache. The belly lax, urinary secretion natural, and the temperature of the leg good.

He was now ordered strong chicken jelly, at intervals with good claret, and ice as desired, and full opiates at night. Upon the 20th, the line of incision was found agglutinated, and the aneurism feeling perfectly solid; the tumour, too, was flatter than before the operation; the same treatment to be continued.

The succeeding day he was not so well; he had been wandering during the night, and at four p.m. I was suddenly sent for, a discharge of blood being reported as issuing from the wound. Upon arrival, I found no blood, but some sanguino-serous discharge, which was welling up the side of the ligature; vent was given to this by a withdrawal of one of the wire sutures. Full opiates ordered, under which the patient slept soundly.

Upon the 22nd (that is, the fourth day from the operation) the integument in the vicinity of the wound exhibited a dusky yellow colour, and pain was complained of in the region of the liver, the surface of the skin over which was tense and somewhat shining. This cellulo-cutaneous swelling extended rapidly, passing upwards for eight inches in the direction of the axilla during the day and night, so that upon the morning of the 23rd it was upon a level with the nipple. Broad straps of adhesive plaster were now drawn from the opposite scapula *tightly* round and across the chest, thus mechanically preventing extension of the swelling, whilst looser straps brought from behind supported the tissues over the ribs; more of the wire sutures were withdrawn, so as to liberate the orifice of the wound. Madeira was substituted for claret, and beef essence for the chicken jelly.

Hiccough, however, set in towards evening with vomiting of small quantities of fluid resembling coffee lees acted on by the gastric juice. A large sinapism was now applied over the epigastric region, and burnt brandy with black drop freely given.

Upon the 24th he was sad and desponding; the vomiting had ceased, but the hiccough continued, and the cellular inflammation, though stopped above, was descending, and had already reached to the trochanter. Here, again, the strapping was adopted, commencing from the inner side of the thigh so as to obtain a firm purchase, but not entirely encircling the limb.

The bowels had not acted since the operation, and the belly being somewhat tympantic, an enema of warm mutton broth with a tablespoonful of common dinner salt was thrown up, but without producing feculent evacuation. The discharge from the wound had become considerable, and contained bubbles of air.

Upon the 25th he was better, the hiccough having ceased, the discharge being of a more healthy character, and the patient having rested well under the use of black drop. He took also an egg for breakfast, and a sole for dinner, which he asked for.

Towards evening, without any apparent cause, the whole aspect of the case was changed. He was now sighing and desponding, the belly very tympantic, and the side of the chest intensely painful. The secretion of urine, too, which up to the present had been copious, now suddenly stopped. An injection of six ounces of beef tea, with four grains of quinine, and a glass of brandy, was thrown up the rectum. A mixture containing ten grains of chlorate of potash to the ounce given every three hours, with a pill of three grains of quinine every six hours, and milk and brandy as desired, together with essence of beef (cold in jelly) each hour. Towards night he was visited, in my absence from town, by my colleague, Professor Hargrave, who found him worse; the extremities cold, the hand picking at the bed-clothes, and the pulse barely perceptible at either wrist. He was ordered brandy in increased quantity, heat to the extremities, and three grains of quinine every four hours.

Upon the 26th he had rallied again, the pulse had become fuller and firmer, and the pain in the pleura had subsided. The discharge copious, but yet healthy in appearance, with lumps of dead cellular tissue, which had been cast off, welling up through the pus. No action having taken place from the bowels for some time, and the patient's mind being anxious upon this point, a lavement of ten ounces of strong mutton soup with a tablespoonful of common salt was again administered. This brought away one or two portions of feculent matter. The following day there was an increased improvement in the patient, who expressed himself as quite easy. I should mention that a water-cushion of very large size had been employed in order not only to afford support to the back and lumbar regions, but by pressing forward the matter contained between the ribs and integuments of the chest, thereby prevent it from burrowing backwards. The patient was now taking two fresh eggs daily, essence of beef, brandy and milk, meat gravy with madeira as desired. Ten grains of the saccharated carbonate of iron and three grains of sulphate of quinine were also given every six hours. The pulse was now reduced to 88, and all looked favourable for recovery.

(*To be continued.*)

Correspondence.

THE QUACKS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—My father and myself were the earliest supporters of the Medical Circular, when practising in the county of Durham at Ebchester twenty years ago. My two brothers, Dr A. Bolton of the Newcastle Infirmary, and Dr. W. T. Bolton of Ebchester, retain with me a very sincere respect for the bold spirit of independence with which the MEDICAL CIRCULAR has hitherto been conducted.

Since its alliance with the MEDICAL PRESS of Ireland, I regard the publication with increased interest.

In the "Anatomy of Quackery" years ago, it did great good. In later life, when through "Detector" it boldly revealed the misdoings of scoundrels who insult decency, plunder the public, and deprive the legitimate profession of their due, it conferred an additional blessing on civilisation throughout the world.

May the day be not far distant when an officer of health, under the direction of Government, may summarily suppress the evil by stamping it out before a bench of magistrates whenever it crops up, either by post, by placard, or by crime. I believe every means is used to intimidate both young men and young women by these wretches, and when sufficiently frightened by letter and pamphlet, the hand is in the pocket, the robbery is completed, and the wretch more disreputable than burglar or highwayman is allowed to escape.

The Home Secretary may soon find a speedy and specific remedy for this malady.

I am, Sir, Yours &c.,
Leicester. JOHN A. BOLTON, M.D.

Medical Gleanings.

THE HEALTH OF NEW YORK AS AFFECTED BY THE LIME-BURNERS.

THERE are in the city four lime-kilns, consuming over 20,000 tons of oyster shells per day. Each ton gives off about 1,100 barrels of carbonic acid. This will make the total of 88,000 barrels of carbon poured out daily and spread over the city to be inhaled by the people.

THE CULPABILITY OF PHYSICIANS IN DEATHS FROM OVER-DOSE OF REMEDIES.

JUDGE FISHER, of Washington, in a recent trial for manslaughter, charged the jury that a mere error of judgment should not be punished, for all are liable to error. If the defendant had given medicine for the purpose of relieving the patient, and by mistake prescribed an excessive dose, he is not guilty of manslaughter. If there was wilful rashness, if he cared not whether the medicine killed or cured, it would be different from a case where medicine is administered with honest intentions. It has been testified that this was one of the prescriptions which it was designed should not be administered after relief was had, and that deceased was relieved by the first dose. The physician was not responsible for the administration of the second dose, and they should acquit him, The jury after a short absence returned with a verdict of not guilty.—*N. Y. Med. Record.*

Medical News.

DEATH OF A CHILD FROM AN OVERDOSE OF MEDICINE.—An enquiry was made by the Leeds coroner, on Tuesday week, into the death of a child, seven weeks old, named Charles Buttrey. The child had been suffering from a chest affection, and the mother, in her anxiety to alleviate his sufferings, procured a bottle of Washington's cordial. A small quantity was administered to the child, and it soothed him into a sleep out of which he never awoke. The jury found that death had been caused by "an overdose of cordial containing opium given by the mother to alleviate pain and without culpable negligence."

HOSPITAL FOR SICK CHILDREN.—The anniversary festival of this institution was recently held at Willis's Rooms. The event in the history of the institution during the past year has been the adoption of a scheme for the establishment of a Country Branch Hospital and Convalescent Home. The committee have taken a lease of a spacious old mansion at Highgate, called Cromwell House, to which extensive gardens and grounds are attached. The number of in-patients amounted to 718, being 36 in excess of those admitted in the previous year. In the out-patient department the applicants for relief numbered 15,143 The annual subscriptions to the hospital had increased from £2,688 3s. 9d. in 1867 to £2,753 13s. 7d. in 1868; and the donations on which the committee had so much to rely amounted to £3,551 15s., being £300 more than the previous year. The subscriptions announced amounted to £1,600 and the new annual subscriptions to £70 10s.

CONTAGIOUS DISEASES.—Last week an important meeting was held at the residence of Mr. Mitford, M.P., in Cavendish square, of members of Paliament, eminent medical men, clergymen, and gentlemen interested in the Health Laws to confer respecting the extension of the act of 1866. Among those present were Lord Charles Bruce, M.P., Sir John Simeon, M.P., Mr. Waterhouse, M.P., Mr. Mitford, M.P., the Hon. Percy Wyndham, M.P., Sir Henry Thompson, Dr. J. E. Pollock, Dr. Mouat (Inspector General of Hospitals), the Rev. E. Wyatt-Edgell, Dr. Myers (of the Coldstream Guards,) Mr. Berkeley Hill, Mr. J. Brandon Curgenven, Mr. G. C. Gascoigne, Dr. T. Fox., Dr. B. F. M'Dowell (of Dublin), and Mr. James Lane. The hon. secretaries, Mr. Berkeley Hill and Mr. Curgenven, reported that letters had been received from rectors of parishes, and from the mayors of different towns, stating they were prepared to urge forward the measure advocated by the association. A meeting had been held in Birmingham under the bishop and leading clergy of the diocese, advocating this purpose, and the movement was proceeding in Bristol, Reading, Newcastle, Dublin, Gloucester, Manchester, Gravesend, Bath, and Chelteham, and letters in support had been received as well from most of the large ship companies over the kingdom. The mayor of Liverpool, the rector, and others of the Municipal Council of that town, offered to attend with a deputation on the Ministry to urge the adoption of the Act, and the Colleges of the Physicians and Surgeons. Many influential persons sent in their names to be added to the committee, among whom were Lord Lifford, Bishop Smith of the Colonial Church, and several rectors of towns. The chairman supplemented the report of the executive committee by passing in review the course of circumstances arising on this question. He referred to the answers given by the Government in the House of Lords, and said that Mr. Gladstone had been more reticent in the Commons. He regretted that the Government had not taken up the matter, as the evil to which it referred was still continuing its ravages. He was happy to say the Bishop of Worcester had taken the side of the association, and was the fourth bishop who had justified the necessity of the extension of the Act. There had been an increase of between fifty and sixty members of the association, which was satisfactory; but he regretted to say that one of the religious societies had taken an opposition view, and had sent papers to members of Parliament urging that no compulsory measure should be taken. The society, however, gave no facts in answer to the statistics given by the association. Reference having been made to the facts that the association for the extension of the Act had no paid officers or offices, and therefore could only leave the society referred to to be answered by some clergyman who had experience of the practical working of compulsory treatment as against the present position of things, the general business of the meeting was proceeded with. Lord Lifford and Sir John Simeon, M.P., were elected on the committee, the adoption of the report, which contained statistics contrasting the condition of towns to which the Act was applied with those where it was not applied, and proved that the health of the first class was vastly improved and vastly superior to the second in point of freedom from disease, was moved by Mr. Waterhouse, M.P., seconded by Sir J. Simeon, who said he should use his exertions to extend this Act, as he knew the populations of the large towns would be benefited, and the immorality decreased. The chief obstacle to be overcome, he said, was the "flying-in-the-face-of-Providence" argument, and he assured the meeting that he knew some of the chief dignitaries of the Church who were in favour of the association's views. The report was carried, and it was thus announced that branch associations, conducted by clergymen and gentlemen, who were convinced of the evils of leaving matters as they were, had entered into communication with the association for the purpose of bringing to bear upon the Imperial Government the views of the municipal governments all over the kingdom. The vast good the Act had done was referred to by Lord Charles Bruce, Dr. T. Fox, Dr. Myers, who stated that Colonel Michael Bruce, of the Coldstreams, was in favour of the Act, and by other gentleman, who declared that while they held the "continental system" in utter abhorrence, as far as regarded licensing, still they had found that compulsion had worked most successfully. It was at length agreed that the executive committee should have full power to take such measures as were thought proper for bringing this organization of public opinion to bear upon the Government. A cordial vote of thanks was given to Mr. Mitford and to the hon. secretaries, and the meeting closed.

NOTICES TO CORRESPONDENTS.

Dr. McMahon Murphy's note shall have early insertion.

Dr. Hayes's paper is in type.

C. C. writes from Nice respecting the letters from our Special Correspondents :—"The most noted places for bad smells are Nice, Cannes, and Monaco. The part of Nice where the smells that tackle your nose are the strongest and most disagreeable is the most fashionable portion. The best hotel in Nice is the Grand Hotel—and why? Because just in front they have just built over the river a garden on arches. A few ladies, wiser than the rest, as they pass in front of the *Hotel des Anglais*, wet their handkerchiefs with eau de cologne and hold their noses until they have passed the bad smells."

D. D.—The work is published by Messrs. Churchill.

Drs. J. A. Bolton and C. Griffiths, new subscribers, will please receive our best thanks.

Communications, enclosures, &c., have been received from Mr. H. B. Tuttiell, Ventnor; Mr. J. C. Proctor, Lydd; Dr. Palfrey, London; Dr. Lory Marsh; the Secretary, Medical Society of London; Mr. Harris; Dr. Caplin, London; Mr. Short; the Secretary, Anthropological Society; Dr. Paine, Philadelphia; Mr. C. Griffiths, Bristol; Dr. Leonard Sedgwick, London; Sanitas; Mr. Cottell; Dr. R. Crothers, Nice; Mr. Balmanno Squire, London; Mr. W. S. Whatford, Brighton; Mr. Nourse, Brighton; Dr. Davey, Walmer; the Secretary, Pharmaceutical Society; Mr. Holden, Liverpool; Mr. W. W. Wiseman, Ossett; Mr. J. B. Blackett, London; Mr. W. ALOINA.

T. and H. SMITH, the Discoverers of this, the CRYSTALLINE PURGATIVE PRINCIPLE of ALOES, vide "Edinburgh Monthly Journal of Medical Science," for Feb. 1851) continue to prepare and supply it. They have the gratification of knowing that the most eminent of the Profession prescribe it, to the exclusion altogether of the various kinds of aloes.

Orders executed direct, or through any Drug House, by T. and H SMITH and CO., 69 Coleman street, City, London, and 21, Duke street Edinburgh.

TASTELESS PILLS—COX'S PATENT.—

Surgeons and Chemists supplied with an excellent Aperient Pill (the formula for which will be forwarded), covered with a thin non-metallic film, rendering each Pill perfectly tasteless, at 1s. 6d. a gross. Postage 2d. They present an elegant pearl-like appearance, and may be kept in the mouth several minutes without taste, yet readily dissolving, even in cold water, in an hour. Any formula dispensed and covered, and samples, with a list of pills from 130 different forms which are kept in stock, will be forwarded free on application to COX and CO., Tasteless Pill Manufacturers, Brighton.

SIX MEDALS—London, New York, Dublin, and Paris.

JAMES'S FEVER POWDER.

4s. 6d. PER BOTTLE, PACKETS 2s. 9d. EACH.

PREPARED and sold by J. L. KIDDLE, 31 Hunter street, Brunswick square, London.

This preparation has been so extensively employed by the Faculty and its merits so universally acknowled by the public at large, as to render all further remark on the part of the Proprietor unnecessary To be had of all Wholesale Druggists.

BARNES'

PURE ETHERISED COD-LIVER OIL

Augments the pancreatic secretions, and improves digestion!—Vide Paper read at the Oxford Meeting of the British Medical Association, "On the Use of Etherised Cod-liver Oil in the Treatment of Phthisis."

Further experience shows that 72 per cent. of the cases treated with it improved.

No 1, minimum strength, is generally used, but occasionally No. 2, medium, and No. 3, maximum strength, are found to be required.

Dose, Two Fluid Drachms.

Prepared with the best Oil, and sold in Imperial Pints and Half-Pints, also per Gallon.

J. B. BARNES, Pharmaceutical Chemist, 1 & 2 Trevor terrace, Princes' gate, S.W., London.

Prize Medal Awarded in 1851, *for Valerianic Acid and Valerianates.*

Lecture.

ON FIBROUS TUMOURS OF THE UTERUS.

By James Palfrey, M.D., M.R.C.P.,

Assistant Obstetric Physician to, and Lecturer on Clinical Obstetricy at, the London Hospital; formerly Obstetric Physician to the Farringdon Lying-in Charity, and to the Metropolitan Free Hospital, and to the Surrey Dispensary, &c., &c.

LECTURE IV.

Since I last addressed you, Gentlemen, the thought has occurred to me that, seeing we have now had under our consideration the pathology, etiology, symptomatology, and diagnosis of fibrous tumours of the uterus, our time would not be mis-spent if we, before going on to the concluding portions of our subject, summarised, as it were, our progress; and I think we cannot do this more usefully nor more practically, than by placing before you the particulars of a case of fibroid disease of the third, or sub-mucous variety, as it will come before you hereafter; and further, seeing that no description can be so truthful as that we find in an actual case of the disease itself, I propose to give you the particulars of a case now under our treatment here. In January, 1863, I was requested to see M. P., a tall fair woman, forty-one years of age, who presented a blanched and cachectic appearance. I learned that she was the wife of an inspector on the S. E. Railway, to whom she had been married eleven years; that she commenced to menstruate at thirteen years of age, and from her sixteenth year her period had always lasted six or seven days, and that at times a white discharge and some bearing down troubled her. In her twenty-ninth year she married, and fourteen months afterwards she bore a daughter, now living; her labour was long, and her suffering severe; she has not since been pregnant. Her convalescence was very protracted, she being compelled to keep her bed seven weeks through a "falling of her womb;" five months after her delivery, her health being then in so feeble a state, she weaned her infant, and her menstrual periods returning, she found the flow more profuse than ever; soon a constant vaginal tenesmus was added, and now, for the first time, great pain both before and after sexual congress was complained of. Two years after delivery found her no better, and at this time lumbar and hypogastric pains of a persistent nature and great severity induced her to seek advice, but no examination of the uterus was then made. Gradually these troubles increased, her bleeding becoming more and more excessive and prolonged, until the interval between each attack was but a few days in duration. Her condition getting at last serious, I was called to see her. Upon examination of her uterus, I readily ascertained that in the posterior wall, about its centre, there was a hard sub-mucous growth, as large as a full-sized orange and of uneven surface, bulging into the uterine cavity; her womb was retroverted, not very moveable, and situated low in the pelvis; the os uteri slightly gaping, the anterior lip being a third of an inch longer than the posterior. Directing the point of the sound into the hollow of the sacrum, it readily entered 4¼ inches; its passage was immediately followed by some bleeding. Very moderate pressure upon any portion of the uterus produced great pain; some spasm after each micturition, which was frequent, was also complained of; a slight mucous discharge was generally said to be present in the interval of her period. As far as we could ascertain, all her other organs were healthy; altogether this woman presented the appearance of a person in the most profound state of anæmia, a well-marked "bruit de diable" being audible, her pulse was rapid and feeble, her stomach irritable, and latterly she had rejected all solids. Complete rest in bed, careful and judicious nursing, the use of the cervical plug and ice, after each bleeding had lasted three clear days, some repeated leechings in the interval of her menstruation sufficed in a few months considerably to relieve her more urgent symptoms. Subsequently, the prolonged use of the perchloride of iron internally, and the uterine douche during the intervals of menstruation tended much to improve her general state; yet her monthly flow continued profuse, and soon after the discontinuance of the plug it was reported to last ten days, attended by the passage usually of large clots. In much about this condition she went on, sometimes better, sometimes worse, the bleeding and pain being the most troublesome of her complaints, until the January of 1866, when, her husband having deserted her, she was obliged to undergo long-continued exertion; this, associated with the mental anxiety she passed through, produced an alarming aggravation of her symptoms, and, in April of that year, she was admitted as an in-patient of the London Hospital. My colleague (Dr. Head) in the following month, freely incised her cervix, and this proceeding was followed by a cessation of the hæmorrhage, her next, and, in fact, all her subsequent periods lasting usually four, but never more than five days. Again, prolonged rest and good nourishment (added to the above-mentioned operation) did their work, and some nine weeks after her admission to the hospital she was made an out-patient, being then in greatly improved health. At various times since then, Mrs. P. has presented herself for advice, her chief troubles being a bearing down and pain. For the former symptom a well-adjusted bandage was procured for her, and for the last-named she was supplied with a pill containing 1 grain of the ext. of Indian hemp and 2 grains of ext. of hyoscyamus, which she has taken from time to time. At my request, this patient presented herself this day, May 12th, and I have had an opportunity of ascertaining her exact condition. I find the whole uterus much increased in size, and now filling the cavity of the pelvis; the tumour can readily be felt, extending to 3 inches above the pubis; the os uteri is still somewhat open, although the incisions have in a great measure contracted; the cervix is now all but expanded from encroachment of the growth. The sound with ease can be passed over the surface of this now considerable growth to the exact extent of 6½ inches, and after her bladder had been emptied by a catheter, the sound could very easily be felt through the anterior wall of the womb. She complains of almost incessant pain and a distressing bearing down; in addition, I find her rectum flattened, and a mass of highly irritable, vascular hæmorrhoids just within the anus; her bladder gives her much trouble, she being obliged, during the past seven months, to pass water during the day every thirty or forty minutes, and frequently, although less often, at night. She menstruates, she says, five days, and has never had a return of the profuse bleeding since the operation; she suffers most a week before the accession of each period, but for a few days after her menstruation has passed off, she is sensibly relieved of all her symptoms; she has for a year had a profuse leucorrhœa. Her appearance now is that of a woman who has passed through protracted and severe suffering: her face is pale, worn, and sunken; she is emaciated, and exceedingly feeble; her ankles are swollen, and varicose veins have appeared in her right leg and thigh.

The above, Gentlemen, you will find to be the general history and progress of most of these cases as they will present themselves to you for treatment; of course, every individual instance will afford for your observation points peculiar to itself, both in its pathology and its management. You must, as you progress, accustom yourselves more and more to deal with each case upon its own merits and its necessities, rather than upon any fixed general notion that may at this present time have taken possession of your minds as the result of my teaching; and should any of you in the course of your investigations discover that any of my advice to you is erroneous, or should you, after careful examination, ascertain that my ideas upon either the pathology or therapeutics of this, or any other disease, are not in consonance with what you actually find present as the result of your own clinical research, I pray you at once discard my views, throw over my recommendations upon any such points of treatment, and strike out for yourselves a path more in accordance with the extended and advanced investigations which you will have carried on. I assure you it is only in this way that true progress can be made in any branch of our great art; and it is to you we look to mature and ripen ideas, and perfect proceedings which in our hands at present may be but the rude blocks, which it shall be your privilege to chisel and beautify into the finished and complete form of certain truth and complete success.

And now I need detain you but a very short time upon the subject of the "prognosis and termination" of these hard tumours of the womb, for I have already indicated to you as we have progressed the principal points on these heads that are important for you to become acquainted with. Recall the statement I made to you when closing my first lecture,—that in my belief a fibrous body is *never absorbed*—and when they do undergo a natural cure, it is as a result of a degeneration into the calcareous substance already described to you, or they soften down and are expelled piecemeal from the uterus; this latter change I believe to be invariably due to injury, either in a manner similar to that which happened in the case I have narrated, or, in still more rare cases, as a result of great pressure during the act of parturition, so that I advise you in pronouncing an opinion as to the ultimate issue of a case of fibroid, to dismiss from your minds as *highly improbable* the chance that your patient may be cured of her malady in either of these ways, but although a cure by these means is so problematical, yet our prognosis as a rule, may be a hopeful one. Bear in mind always, that these growths are not of a malignant character, that they are slow in their progress, and should you, by calm and judicious management, be able to tide your patient over the period of her sexual activity, you may then very reasonably hope that the dangers of her condition are materially lessened. This remark is particularly applicable to growths of the subperitoneal form which seldom shorten the life of those who are the subjects of them, these tumours often pass through what I will term a period of latency extending over many years, more especially after they have ceased to be obnoxious to the return of those congestive conditions which accompany each menstrual period.

Always, however, express an anxious opinion when you are called upon to deal with a case of interstitial or submucous fibroid "*occurring in early life*," remember that their nutrition being at its height and the bloodvessels which supply the growth being large, the development of the tumour will be proportionally rapid, in time the hæmorrhage that so constantly forms so dangerous a symptom of these forms of the disease will be just so much the more profuse and frequent in its occurrence, and less manageable, so that your patients being weakened and exhausted thereby are more liable to fall victims to any accidental malady that may attack them. I say, be very guarded in expressing an opinion on a case of this kind for I believe the patient's danger can be pretty accurately, measured by the position of the tumour, and the period of sexual activity at which it is developed. When describing to you the hæmorrhage that accompanies these growths, I said that it was a rare circumstance for that symptoms immediately to prove fatal, of course in this remark are not included those instances of abortion caused by the presence of a growth of this kind. My experience of these cases has been indeed painful, for on several occasions I have been a witness to rapid exhaustion and death from the impossibility of obtaining contraction of the womb upon the growths after miscarriage, and I will just mention here that in those cases in which pregnancy by care can be prolonged to term, the greatest caution will be necessary to prevent a fatal hæmorrhage after delivery destroying the patient. The records of obstetric literature too, bear evidence of the frequency with which these fibroids complicating delivery, prove fatal in other ways, which it would be foreign to my purpose here to enter upon, further than to say that should parturition be passed through in comparative safety, the subsequent process of sub-involution is invariably retarded and interfered with. I do not know that I shall find a more fitting opportunity to answer a question that was put to me by one of my class, on a recent occasion when, examining the case of a woman, the subject of a large fibrous tumour. Do these hard growths ever undergo cancerous degeneration? was the query very properly put to me. Well, this is a question exceedingly difficult satisfactorily to answer for the evidence upon the point is certainly contradictory. Dr. West asserts positively that malignant degeneration of a fibrous tumour never takes place, and various other obstetric authorities, among whom I may mention, Dr. M'Clintock, agree with this opinion, on the other hand it is but just that I should tell you that some eminent men hold the reverse to be the fact. Some time since, I had the pleasure of meeting Sir James Simpson in consultation, and at that time, when speaking upon this point, he expressed to me his belief that fibroids do undergo cancerous degeneration and notably in those cases where malignant disease was hereditary. My father-in-law, Dr. Lever, held an exactly similar opinion, Dr. Ashwell also was of this number. Dr. Atlee believes that a fibrous tumour does "occasionally degenerate into cancer," and Mr. Paget speaks of "malignant fibrous tumours." I reget to tell you, I am unable, from my own experience, definitely to settle this vexed question for you. Certain it is that in three well marked cases of fibroid disease, which I have seen in consultation, cancerous disease has subsequently attacked the growth, and also the uterus in which it was contained; in two of the instances the neck, and in the third the fundus, and subsequently the whole tissue (including the contained growth), of the womb became infiltrated. In each of the above cases a *post-mortem* examination placed the nature of the condition beyond doubt (had any existed). In the first case which I saw with the late Mr. Travers, of Rotherhithe, the woman, æt. fifty-seven, had long been under his observation and treatment for the hæmorrhage and other symptoms, attending a large interstitial fibrous growth in the anterior wall of the womb. A somewhat sudden increase in pain, together with the passage of some blood with her urine, induced Mr. Travers to ask me to see this patient with him. I found her uterus very much enlarged, and fixed to the tissues in the anterior pelvic wall, the cervix indurated and split up, the process of ulceration just beginning in the anterior lip, softening and breaking up rapidly followed, and nine months after my first visit this woman succumbed to the intense suffering and exhaustion accompanying her disease. An examination after death revealed to us the remains of a large growth, a considerable portion of which, in common with the other portions of the womb, had been eaten away and expelled by the ulcerating process which you all know is common to the last stage of medullary carcinoma of the uterus. Such portion of the original growth as remained in the upper portion near the fundus was found infiltrated with cancerous deposit, the inguinal glands on both sides were affected, as also the liver and right kidney.

I shall not detain you by giving the details of the other two cases. I will content myself by assuring you that the evidence of the presence of a fibroid before the manifestations of symptoms of malignant disease in each case was complete, and the subsequent degeneration of the growth was abundantly proved by the symptoms, which supervened during life, and the appearances and conditions found after death, and these not observed by myself only, but also in each instance by more than one other observer. But it may be urged, these cases may each of them have occurred in women by hereditary taint, predisposed to malignant deposits and, such being the case, they were simple co-incidences. Gentlemen, I frankly admit the great weight of this objection. Hence I feel at present that it is impossible to speak to you with certainty on the point, and we must leave the question (and a very grave one it is), for future pathologists to decide, these cases have, however, left on my own mind a very decided impression, upon which I invariably act, viz:—that if in the investigation of the history of a case of fibroid, *clear evidence* is placed before me that malignant disease has been present in the ancestors of the patient, I modify my prognosis accordingly, and I believe you will do wisely (on this point at any rate), to follow my example. And now leaving this uncertain and undecided question, let me for a moment point out to you one interesting circumstance which you will, I am sure bear in mind. I have, in a previous lecture, told you that now and then a fibrous body springing from the *sub-peritoneal* tissue after arriving at a certain size becomes detached from its position in the uterine wall, and is found loose in the abdominal cavity, in consequence of its pedicle having become thinner and thinner and finally broken. Now, I must tell you that the evidence is clear and unmistakeable, that the occasions are by no means rare, that when the peritoneal investment of a growth of the first variety becomes the subject of active inflammation, it contracts adhesions to other parts of the abdominal parietes, and the growth then becomes fixed in its new position, and should it so happen that this new position is the surface of the bladder or rectum, the alternate dilatations and contractions of these viscera and the constant changes in the size and position of these organs which result from such dilatations and contractions, exercise a considerable traction on the tumour. This, of course, tends to elongate, and so attenuate the pedicle of the fibroid by which it was originally attached to the surface of the uterus, this traction being prolonged, ultimately complete separation of the original pedicle takes place, and the tumour is then really transplanted. I am indebted to Dr. Turner, of Edinburgh, for the above description of this interesting process. It has occurred to me on some few occasions, to see in the dead-house, growths which undoubtedly have undergone this *transplanting*. And now leaving these doubtful points, turning from these questions, many of which are open to such controversy, let us pass to the all important subject of the treatment of fibrous tumours of the uterus, and I propose still to adhere in this division of our subject to the anatomical arrangement which has guided us throughout. I am pleased indeed, to tell you, that however uncertain and open to question many portions of our subject have hitherto been, I shall be able, as a rule, to speak confidently upon many points in the management of these fibroids, and once having satisfied yourselves of the nature of the case with which you are dealing, the steps you will adopt, and the remedies you will employ for the cure of the disease, or failing that, the alleviation in the patient's sufferings will be a matter of no difficulty to you to determine. At starting, however, let me answer one or two questions upon the general therapeutics of these growths that will assuredly present themselves continually to your minds when advising upon the treatment of uterine fibroids, and first: Is a fibrous growth in any position, upon, or in, the uterus capable of being radically cured by drugs or absorbed by any form of medication? Gentlemen, I unhesitatingly declare to you that I know of no drug or combination of drugs that will exert, in the slightest possible degree, any *curative* influence upon a uterine fibroid. It was my lot in the earlier portion of my life to have seen women who were the subjects of fibroids in one or other of the positions I have described, who not only for months but even for years, submitted themselves to long continued courses of mercury, iodine, bromine, and other potent medicines, who, in addition adopted inunctions —and paintings and plasters—composed of these and similar drugs, and yet at the termination of this treatment their tumour had undergone no beneficial change, but their constitutions were damaged, and their blood impoverished and deteriorated by the introduction long persisted in of one or more of these remedies? which had too often tended only to hasten a marasmus, or even accelerate a profound cachexia. More recently I have fairly, and I trust without prejudice, given a prolonged trial, both in public and private practice, to the chloride of calcium, (hydrochlorate of lime) which has been highly recommended as having the power of actually absorbing and removing these growths. Truth compels me to say this agent has in my hands utterly failed to be of the slightest use. Now, believing as I do, that drugs are wholly powerless to effect the removal of these hard bodies, I hold that you dare not run the risk of injuring your patient's constitution by administering them to her. You are not justified, I repeat, in doing direct harm, where you are unable to effect positive good. You will not be surprised then to hear that I have long ceased to put my cases of fibroid disease through a course of so called absorbent medicines. It would be exceedingly unfair however, were I to leave this statement of mine concerning the powerlessness of drugs to remove one of these growths without informing you that there are physicians still living who hold an opposite opinion. It was but a very few months since, I was requested by a medical man in the south of London, to visit with him a lady who had for many years been suffering from a large fibrous tumour of the uterus. Eighteen years ago Dr. Lever saw her, and then diagnosed a hard tumour springing from the uterine wall. I have in my possession his notes, both as to the nature, size, and relations of the growth at that time, as also the treatment he then suggested. When I saw the patient her abdominal cavity was almost filled with the enormous solid mass which also filled the pelvis and descended to within a couple of inches of the outlet. Symptoms indicative of great pressure had given considerable anxiety for some time before my visit, and more recently dyspnœa had at times added to the patient's misery. I expressed a very decidedly unfavourable opinion as to the issue of the case, pointing out that the disease had apparently run the best part of its course, and that before many months the patient would succumb. The husband of the patient being very properly informed of my opinion, became alarmed, and a few days subsequently to my seeing this poor woman, she was visited by another obstetric physician, who having duly examined his patient assured the anxious husband, he need have no longer any alarm for he could rest happy in the certainty that very much by medicine could be done for his wife, and in consultation with the gentleman in attendance, he strongly urged the prolonged administration of the iodide of potass; and the friction of the belly with some sedative liniment, adding that this course *would certainly* result in the removal of a large portion of this immense tumour. Well, gentlemen, doubtless this eminent obstetrician most conscientiously believed in the power he possessed to perform the promise he made, yet I will frankly confess to you that (since as is my faith in the power of the iodide to absorb and remove deposits of a different sort) I have not yet arrived at that point that I can believe that a small quantity of any drug (for whatever be the dose administered, it must be relatively small) given by the mouth, then entering through the stomach into the general circulation, has the power of influencing for good, in the remotest degree, a tumour of this or any other size. Again, on this point, I will tell you that, during the interview I had with Sir James Simpson in December last, he assured me that he had watched the gradual removal of small fibrous bodies under the persistent use of the bromide of potassium, in doses of from forty to sixty grains, frequently repeated and long persisted in. The opinion of this eminent authority has at all times carried with it great weight in my mind, and deservedly so; yet, gentlemen, I cannot forget that during the years 1861, '62, '63, and '64, I submitted a series of these cases of fibrous tumours to experimental courses of treatment; every medicine known to exert, or supposed to have the power of removing or lessening these tumours, was fairly, and I may add honestly, tested, not by internal administration only, but also by the various other means advised by their several supporters; and I repeat to you, that in no single instance did I witness the least diminution in one of these growths, or any improvement in the general condition of any of the patients under treatment. On the contrary, I had numerous examples before me of the injury the long-continued use of some of these agents produced upon the general health of the sufferers; and I feel no moral doubt whatever that the majority of these women, so far from being benefited by the treatment to which they were subjected, were damaged, and their troubles increased by the useless introduction into their blood of medicines wholly impotent to cure them of their fibroids; but potent as we know the preparations of mercury are, when steadily given, to decompose the blood, and to exert its destructive agency upon the fibrine and albuminous portions of that fluid; and the same observation, in nearly an equal degree, I believe obtains with respect to iodine and its compounds, and bromine and its salts. But permit me to guard myself from misconception. You have just heard how entirely faithless I am in the efficacy of drugs to remove or even lessen these growths, yet I would not have you go away with the impression that I have no faith in drugs in the *treatment* of fibrous tumours of the womb. Gentlemen, it is not so. All of you have doubtless seen how perfectly we are able to relieve and to keep in check nearly every distressing symptom that attends the development and progress of these neoplasms. Need you a proof of this? Have you not frequently seen among our patients women, the subject of these tumours, who have presented themselves to us, suffering intensely from persistent uterine colic? Have you not, I say, seen these women relieved, as if by magic, by the hypodermic injection of a quarter of a grain of morphia in solution in the neighbourhood of the growth? Again, are you not constantly witnessing the manifest improvement in the health of these sufferers by the timely administration of a free saline purge to relieve the wearing, exhausting vaginal and rectal tenesmus, which is such a sure indication of pelvic engorgement, and which, in growths of considerable size, forms so conspicuous a portion of the troubles and sufferings of the patient? I am sure you have. I could easily multiply examples of the value of medicines in relieving these conditions, but the above are sufficient, I hope, to convey to your minds the idea I am anxious to give you. My time has now expired, and I must leave until our next meeting the further consideration of this subject of treatment.

MEDICINE, MAGIC, AND WITCHCRAFT.

By M. Donovan, Esq.,

Honorary Member of the Philadelphia College of Pharmacy.

The origin of the mysteries of the Cabbala has been differently represented by different inquirers. By some it has been said that the Cabbala was revealed to Adam by an angel, who brought him a book containing it; but the book being lost at the period of the Fall of Man, was restored at the earnest prayer of Adam; and being again lost, during the wickedness of mankind before the flood, it was restored to Abraham. This, at least, is the account given by Maimonides who flourished in the twelfth century, a man of the highest acquirements, a learned physician and Rabbi, who epitomised the doctrines of the Jews in thirteen articles of faith.

The secrets thus preserved, constitute the Cabbala; and were deemed by those who participated in them, the most sublime of all sciences: yet these traditions, so prized and tenaciously adhered to, are said to have retarded the progress of improvement amongst the Jews, and to have obstructed their intellectual advancement.

Not the least important of the mysteries of the Cabbala were those belonging to the healing art. By transpositions and new combinations of the letters constituting sacred names in scripture, those skiled in the pursuit pretended that words could be formed which possess the virtue of healing wounds; and of producing effects far more wonderful. A Jewish physician, well skilled in the cabbalistic department of his art, having been detected in adultery, was condemned to the stake, but at the place of execution he so bewildered the officials that they mistook a horse for the doctor, and burned the poor animal in his stead. This statement is given on the authority of a learned Rabbi.

No doubt the medical mysteries of the Cabbala assisted in introducing various superstitions which disfigured medicine for many centuries. Mystery would be promoted by the sordid, while mankind, ever ready to lend assistance to those who are skilful enough to cheat them dexterously, would assist in deceiving themselves. That interested motives did cause a coalition of medicine and superstition is apparent in the history of the dark ages when the treatment of disease, to a great extent, fell into the hands of the monkish orders, and in the cloister suffered its worst degradation. Astrology, alchemy, magic, and medicine were confounded together and practised by the monks, with great profit to themselves, but little benefit to their patients, until Royal edicts restrained them from interfering with the sick further than for the benefit of their souls. Of the kind of knowledge of medicines possessed by the monks, and the character which it nevertheless supported, an instance is given by Otto Tachenius,—"a certain dull friar (he says) hearing sal prunellæ to be recommended by chemists, came by night to a skilful apothecary and demanded of him whether this sal prunellæ was extracted out of sloes or garden plums (for the friar knew that prunes meant either): yet these are the men who would be accounted by vulgar idiots and silly women the only medical practitioners." Tachenius, although he sneers at the ignorance of others, gives a tolerable proof of his own, when he informs us that "salt of tartar digested with any metal turns it into running mercury." His commentaries on Zwelfer's "Hippocrates chimicus" evinces more malice than knowledge, and displays much of his own character.

To control the powers of darkness by incantation was, in the early ages, the province of those who professed a knowledge of medicine. Lucan has immortalized the Thessalian sorceress Erictho, who was celebrated for her knowledge of magic, medicine, and poisonous herbs. Sextus, son of Pompey the Great, induced her to raise a spirit by her incantations by whom he might be informed as to the results of the war waged between Cæsar and his father. The story at least proves the antiquity of the connexion between medicine and magic, and we find that the latter was, long after, made use of as a means of assisting the former.

Orpheus, whose music caused even mountains to approach, was in the Argonautic expedition along with Esculapius the surgeon to the fleet. Orpheus, besides music and poetry, cultivated medicine, and according to Galen wrote a book on the art of compounding poisons. Along with such accomplishments, he is pronounced by Pausanias to have been an expert magician. Esculapius himself is said to have dealt a little in charms and enchantments, and to have occasionally cured by music.

Origen shows that magic constituted part of the medicine of the Egyptians, their doctrine being that the human body consists of thirty-six parts, that these parts are under the superintendence of thirty-six devils, one for each part, the names of which were familiar to the Egyptian priest, and being separately invoked by these names, the part affected was healed by its superintendent demon. The division of the kingdom itself was similar; Sesostris divided Egypt into thirty-six names or provinces, and assigned a governor to each.

The first four antediluvian kings of Egypt recorded by the oriental writers named Nakraus, Natras, Mesram, and Aicam, in whose reign Enoch was translated, are represented as having been fearful magicians; and Daluka, Queen of Egypt, who succeeded to the throne after Pharaoh was drowned in the Red sea, was the most accomplished magician of her age. S. Epiphanius declares that magic existed in the time of Jared, a descendant of Seth.

According to Josephus, King Solomon was well skilled in composing medicines for the sick; and, notwithstanding his wisdom and piety, is said to have used enchantments for delivering persons possessed with devils. So high an opinion had the Jews of the extensive acquirements of Solomon, that they believed Aristotle borrowed most of his knowledge from this wise monarch's writings. But if we rely on the apocryphal book "the wisdom of Solomon" we must disbelieve that a prince remarkable for piety would pollute himself by the practice of an art which he deprecated and contemned (Wisdom ch. xxii. 7). "As for the illusions of art and magic, they were put down, and their vaunting in wisdom was reproved with disgrace."

King Solomon, as we learn from scripture, was wiser than all men. He spoke of trees, from the cedar to hyssop, also of beasts, fowl, and creeping things and of fishes. Josephus adds that he made extensive inquiries about them, and "described them all like a philosopher, and demonstrated his exquisite knowledge of their several properties." He adds, "God also enabled him to learn that skill which expels demons, which is a science useful and sanative to men. He composed incantations also by which distempers are alleviated. And he left behind him the manner of using exorcisms, by which they draw away demons, so that they never return, and this method of cure is of great force unto this day; for, (says Josephus) I have seen a man of my own country releasing people that were demoniacal, in the presence of Vespasian." He describes the method. The Rabbins affirm that the writings of Solomon which treated of incantations, were destroyed by Hezekiah; but this statement seems contradicted by Josephus; at least the knowledge of them descended to the first century.

Nechepsus, King of Egypt, wrote on astrology, magic, and medicine; so also did Pharoah, grandfather to Psammeticus. Petosiris, a mathematician of the same country, wrote on these subjects, and explained some departments of medicine on astrological principles; he was of great authority in medicine amongst the Romans. A celebrated Egyptian physician, named Iachen, wrote on enchantments and amulets, and used them with such effect, it is said, that he could arrest the progress of the plague or moderate the ardours of the dog-days. Medicinal spells and charms were in high repute amongst the ancient Egyptians, and indeed the employment of such seems to have spread pretty generally over the world. Aëtius, a Mesopotamian physician who studied at Alexandria, and flourished about the end of the fifth century, gives an account of a charm or spell, which possessed the admirable property of extracting a bone when stuck fast in the throat. The Lydian physician and philosopher, Alexander Trallianus, who lived in the sixth century, and on account of his high reputation was called Alexander the Physician, nevertheless resorted to charms and amulets for the cure of agues, calculi, and gout. That spell which could charm a stone out of the bladder must have been indeed a potent one, and only to be compared with the incantation transmitted to posterity by Cato the censor, which possessed the virtue of reducing a dislocation.

Amongst the Jews, it was believed that internal diseases are manifestations of God's anger, and are inflicted by evil spirits as ministers of His vengeance. Hence the religious did not apply to physicians for relief, but to God or his prophets; and the wicked sought the aid of magicians and idols. Thus, Asa was exceedingly diseased in his feet, "yet in his disease he sought not to the Lord, but to the physicians." Naaman, the captain of the Syrian host, was cured of leprosy by Elisha; and the same prophet cured Hezekiah, who was sick unto death, by an application of figs to the boil. But Ahazrah, King of Samaria, hurt by a fall through a lattice, sent to inquire of Baalzebub to know if he should recover.

With regard to the invention of the ridiculous, but wickedly intended, art of magic, there are several opinions. Some have attributed it to Solomon, others to Kelkeli, a King of Egypt, who lived previously to Abraham; but Pliny declares that Moses, Jamne, and Jotapha, were the heads and founders of magic; the two last said to be the sons of Balaam. About the fifth century a treatise on magic existed, which was supposed to have been written by Ham, the son of Noah. According to Justin, the famine of Egypt was predicted by Joseph through his knowledge of magic.

Concerning the practices of the ancient magicians little information has descended to us. In more modern times there were two kinds of magic, black and white; the former was exercised under a compact with Satan that he should execute the will of the person for a certain time, on condition of receiving the soul and body of the magician at its termination, and the deed of surrender was signed with the person's blood. White magic was practised by means of an intercourse with fairies or aërial spirits, who, without any compact for the surrender of the soul, gave information on subjects proposed, and enabled their votary either to inflict withering diseases or to perform wonderful cures. It was in this way that physicians who professed magic were sought after by those wiseacres who relied more on supernatural cures than those effected in the ordinary course of nature.

One of the offices of the medical magician was the cure of persons suffering under any wasting disorder, for such were supposed to pine under the influence of witchcraft. The process by which an obnoxious person was pretended to be wasted was to place a waxen image, supposed to personify the victim, before a slow fire, and by gradual melting to allow the wax to trickle away in drops. To counteract the much dreaded effects of this ridiculous process, the physician would employ the combined effects of medicine and magic.

Another department of the medical art was the relief of those who, being monomaniacs, imagined themselves possessed by demons, or affected to be so possessed, in order to obtain a transient notoriety. In these times it was believed that adepts in witchcraft might, under a symbol and compact, cause a demon to enter the body of any person against whom ill-will was entertained. They also professed the power of curing diseases by withcraft, and were commonly called to the bedside of the sick. These impostors brought on themselves their punishment by pretending to cure diseases with remedies directed by familiar spirits with whom they affected to hold communication; and it is surprising what numbers endeavoured to avail themselves of this impious mode of relief.

One of the provinces of the reputed witch was to cure diseases by remedies disclosed during dreams—a mode of medical treatment which had its origin with personages of the highest authority in their time. Galen, on several occasions, dreamed of methods of cure which he put in practice, and which ultimately proved successful; once he even opened an artery on the strength of a dream; yet he complains that his patients more often relied on their own dreams than on the utmost efforts of his skill. The Egyptians give credit to Isis for disclosing modes of cure through the dreams of the sick. Pliny mentions the case of a man bitten by a mad dog, who escaped hydrophobia by using the roots of a wild rose sent him by his mother, who dreamt that she was ordered to send them to him. These drowsy revelations were regarded by the ancient Egyptians with the greatest reverence.

The belief in magic and witchcraft, in an ignorant and superstitious age, is less surprising when we consider the performances of some expert practitioners of our own times. One of the least intelligible exploits in that way is, perhaps, that of the African magician witnessed by Mr. Lane at Cairo; he took burning charcoal from a chafing dish, put it into his mouth piece by piece, in a state of ignition, until his mouth was full, and chewed it, occasionally opening his mouth to show the fiery contents, and swallowed the whole.

Medicine is not yet emancipated from superstition; mesmerism is the latest opprobrium. There are, or lately have been, clairvoyants who not only saw the organ diseased, but the remedy; and there have been patients who employed them.

Our Analytical Department.

COCOA.

REPORT ON THE QUALITY AT PRESENT SUPPLIED TO THE BRITISH MARKET.

The object of these Dietary Reports is to place before the public a succinct account of the present state of trade as regards each article used by the consumer. Such reports serve the public directly and indirectly; directly, by showing the actual quality supplied, and indirectly by raising the standard of the supply. These analytical reports (which should especially interest the medical profession), we propose to execute without favour or ill-will to anyone. Another reason for the publication of these articles arises from the fact that analytical chemistry, which has done so much for the food supply, is largely abused, and lowered to the very dregs of puffery. It has become the fashion to garnish every packet of proprietary articles with so-called analytical reports, which frequently mean nothing but recommendations expressed in the most general terms. Even if the analysis is *bona fide*, and comes from a reliable source, it cannot be of any possible use unless accompanied by a written testimony from the vendor that the contents of each packet are exactly made according to the sample analysed; this little point is almost invariably neglected.

Before entering into the especial object of the report, it will perhaps be desirable to give a slight sketch of the history and statistics of this now important article of commerce, for which we are indebted in a great measure to an interesting pamphlet by Mr. James Mann.*

There seems to have been some little confusion in connection with the actual source of the so-called "cocoa." This substance is the prepared fruit of the cacao tree, *theobroma cacao*. This confusion has probably arisen from the similarity of the names cacoa tree, cocoa nut palm, and the cocoa shrub, *theobroma cacao*, *cocos nucifera*, and *arum esculentum*. The generic name Theobroma Cacao—from Θεός and βρῶμα, the food of the gods—having been applied by Linneus, this little incident has not been lost sight of by the vendors of proprietary cocoas, although many of the products so advertised form but poor food for human beings. Columbus brought home with him samples of cocoa, which were immediately appreciated by the Spaniards, and thus commenced its European history in 1520. Dr. Letheby, in his interesting Lectures on Food, originally published in this Journal, gives an account of the chocolate houses in London. There is also an interesting account extant, written in 1690, of the attempt and failure of the English to cultivate cocoa in the West Indian Islands.—(*Harleian Miscellany*, vol. ix., p. 422.)

Cocoa will grow within 25 parallels of latitude, but luxuriates within 15. We receive our supply from Trinidad and Grenada. It is, however, grown in Mexico, Central America, Peru, West Indian Islands, Africa, Mauritius, and Australia.

Cocoa requires a considerable amount of care in its cultivation; but, from the paper of Mr. Mann, it seems to be a remunerative crop. When the fruit is gathered, it is placed on an inclined plane or some other arrangement, so as to allow an acid juice to be drained off. The fruit is then submitted to a process of fermentation called sweating; this process requires watching, for on this part of the operation mainly depends the aroma, colour, and amount of bitterness found in the fruit. After this comes the drying and packing; very essential points, because if mould sets in, from want of care in this stage of the proceedings, the whole is ultimately spoiled as a marketable article. The qualities which are necessary to recommend cocoa to the manufacturer in Great Britain is a pleasant taste and aroma when roasted, with a large proportion of fat to render it workable; this latter point is, however, quite distinct from the quality which should recommend it to the consumer.

---

* Cocoa: its Cultivation, Manufacture, and Uses. By Mr. James Mann.

Thus, Mr. Mann remarks :—"Great stress is laid upon the quantity of fat present, and this because the facility of supplying the consumers' wants in a cheap preparation is dependent upon the extent to which it may be diluted with starch or other cheap matter, which is at present effected to the extent of 50 per cent."

It will be seen from the analyses given in this report that Mr. Mann is below the mark, even with respectable manufacturers.

The numerous methods by which the cocoa nuts are dressed for consumption may be divided into two general classes—"cocoas" which are supposed to be merely the ground and prepared bean, and chocolates in which the cocoa is moulded into cakes with sugar—either for eating *as confectionery, or for infusing, as a beverage.*

Chocolate is the article that was first used in Europe; it is frequently flavoured with condiments. To these we may add "shell cocoa," or the husk of the bean. The husk is sometimes ground up in the inferior cocoas, but is also, under the name of "*miserable,*" and consumed as beverage after infusion. The beverage so concocted is not without considerable epicurean virtue, particularly if used conjointly with the "nibs;" this last being simply the broken bean.

The composition of the bean is here given on three authorities—it will be seen that they differ considerably—and as they are evidently the unroasted bean, it was found necessary to give the results obtained by actual experiment :—

	Mitscherlich.	Payen.	Playfair.
Water	5·6	10	5
Fat (cocoa butter) . .	47·5	52	50
Albumen . . .		20	20
Gluten . . .	15·5		
Theobromine . . .	1·5	2	2
Starch . . .	16	10	7
Cellulose . . .	5·8	2	4
Gum			6
Ash	3·5	4	4
Red colouring matter, &c. .	4·6		2
	100·		

Of these analyses, Mitscherlich most nearly approaches our own, except that in it the amount of fat is decidedly under the average amount contained in cocoa now in the market.

Cocoa contains hardly any vegetable albumen, as properly understood.

The following is given as the composition of the ash, which seems very rich in phosphoric acid :—

Potash	37·14
Soda	1·23
Lime	2·9
Magnesia	16
Sulphuric acid	1·5
Carbonic acid	1·2
Phosphoric acid	39·6
Phosphate of iron (ferric phosphate) .	·17
Chlorine	1·7

Theobromine, the active principle, is a white crystalline substance, somewhat similar to thein, the active principle of tea. It contains—

	Theine.	Theobromine.
Carbon . . .	49·8	46·43
Hydrogen . . .	5·08	4·20
Nitrogen . . .	28·83	35·85
Oxygen . . .	16·29	13·52
	100·	100·

Now, as most of the calculations seem to be based upon the composition of the unroasted bean, we have found it necessary to examine the roasted and unroasted cocoa, and subjoin the result :—

	Raw Trinidad Cocoa. (Sample No. 1.)	Finest Roasted Trinidad Nibs. (Sample No. 2.)
Moisture . .	5·6	3
Albuminoid substance .	19·1	
Theobromine . .	1·2	·98
Cocoa butter . .	46·6	49
Woody fibre . .	4·5	
Starch . .	12	11
Gum, &c. . .	4	
Red colouring matter .	3	
Ash . . .	4	3
	100·	

We may now come to the consideration of the examination of cocoas, with regard to their adulteration, and subjoin a short but practical method, which, with some few special modifications, has been followed out in this report.

Ash, and mineral adulterants.—A small quantity of the cocoa or chocolate under examination should be weighed out and ignited in a platinum crucible, and the percentage of ash calculated from the residual matter. Cocoa is difficult to ignite, and if considerable care is not exercised a little unconsumed carbon will remain. It should weigh from 2·8 to 3·5 per cent., and should be perfectly white; if it is coloured, it is probable that it is adulterated with ochre or some other ferruginous pigment. Estimation of the iron, and a comparison with the analysis of the ash given above, will prove this point. If the ash is white, but yet exceeds the average percentage, some other mineral adulterant is probably present; but if (as is frequently found) the cocoa contains a large admixture of starch or sugar, the percentage of ash will be much lower, as will be seen from the subjoined percentages obtained by actual analyses :—

	Per cent. of Ash.
Cocoa	3·0
Sugar	0·03
Maranta arrowroot . . .	0·216

It must be borne in mind that a little iron frequently gets into the cocoa during the manufacturing processes, but this, as a rule, only slightly injures the whiteness of the ash.

Fat.—A weighed quantity of the cocoa should be exhausted of its fat. We use purified bisulphide of carbon for this purpose, as it answers admirably. The residue after drying is weighed, and the loss, after deducting the percentage of moisture, represents the amount of fat, and very nearly the amount of cocoa, present in the sample. The bisulphide of carbon should be evaporated, and the residue examined to see if it presents the ordinary characteristics of cocoa butter.

Cocoa butter melts at about 84° Fahr.

	Melting Point.
A specimen of pure cocoa butter, manufactured by Messrs. Cadbury, Brothers . .	83·2
A specimen of pure cocoa butter, received from Mr. Cooper	86·3

Flake cocoas, and those in which the husk and bean are ground together, should yield about 46 per cent. of fat, and if ground without the husk, 49. We have allowed in our calculations 50, to give the manufacturer a little margin.

Mr. White Cooper directed attention (*Lancet*, 28th June, 1862) to the utility of the butter obtained from the theobroma cacao nut, as the basis for ophthalmic ointments.

> "This material possesses many valuable qualities, the chief being [these :—It has an agreeable smell, and does not soil the fingers when handled; it does not become rancid; while more particularly, though very firm, it has the property of becoming fluid at a low temperature. It is sometimes a little too stiff, but this fault is readily obviated by combining with it a little olive oil or glycerine."

The adulteration of cocoa with foreign fats is, we believe, not practised.

Sugar, &c.—The presence of this substance can be easily detected by washing the suspected cocoa with cold water, and throwing upon a filter. The cold infusion or filtrate should have no sweet taste, but rather bitter than otherwise, with a taste similar to toast water. The detection of sugar is very easy in this manner, and its amount may be estimated by any of the ordinary methods.

Cocoa is said by Mitscherlich to contain ·6 per cent. of sugar naturally.

The infusion made in the cold should be only slightly coloured, as the red colouring matter is but slightly soluble in this menstruum, if it presents any decided colour, this is no doubt due to the presence of some admixture.

Starch.—If examined microscopically and chemically, it will be found that the cocoa normally contains starch; therefore, qualitative chemical tests are of no value to determine the presence of foreign starch. A quantitative examination might determine this point to a certain extent, but the microscopic appearance of the starch granules (*vide* figs. 1, 2, 3, and 4) at once determines it. (*See* Illustration in our next.)

If the amount of starch be not very small, the appearance on boiling with a small quantity of water is quite characteristic of the presence of that substance; it is quite thick, and forms a jelly on cooling.

The cocoa manufacturers make a statement that the addition of certain proportions of starch and sugar (the principal adulterants now used) are not adulterations; that they render the cocoa less burdensome to the stomach, and more easily digested. There is, however, little doubt that, as Dr. Hassall says, "the real secret of the almost constant use of starch and sugar is to be found in the cheapness" (comparative cheapness) "of these articles, and not in any advantages supposed to be derived from their admixture with cocoa." The same gentleman, however, goes on to state "that, as nature has provided the cocoa bean with 11 per cent. of starch, we are the more disposed to question the accuracy of the position assumed by cocoa manufacturers, that the addition of wheat, potato, and sago flours constitutes any real improvement." So far we quite agree with Dr. Hassall, but the remainder of the paragraph is, in our opinion, as fallacious in its deduction as the statements made by the manufacturer. "What nature does is doubtless well done and sufficiently, and we believe that the quantity of starch proper for cocoa is to be found in the kernels themselves." This is as much as to say that, as cocoa is a natural product, it is not capable of improvement in a dietetic point of view; but to carry out such a theory, every vegetable product should be wholesome, which we know is not the fact, and the whole system of mixing edibles, which system has been pointed out by our gastronomic instincts, must be viewed as a myth.

Although the consumption of cocoa is greatly on the increase, it is still far below that of tea or coffee; and, looking at its comparative cheapness, this position is hardly to be accounted for.

Consumption of cocoa for thirty years :—

Years.	Pounds of Cocoa.
1830-9	1,136,000
1840-9	2,609,114
1850-9	3,437,575
Tea . . .	62,598,493
Coffee . . .	34,763,447

Cost in the year 1859 :—

Cocoa	£166,416
Coffee	2,386,902
Tea	11,219,734

The above may be considered much under the estimation of the consumption of what is sold under the name of cocoa.

The additions of starches and arrowroots were, no doubt, originally instituted to attenuate down the proportion of fat (50 per cent.) contained in the cocoa nibs. Supposing that it is not added in a fruadulent quantity, it is, nevertheless, a mistake, as it is the addition of nitrogenous or flesh formers that is required to make the cocoa a more desirable article of food; or, what is the nearest to this, to reduce the fat by expression or solvents, and thus relieve the cocoa of the great excess of heat-givers, by partially removing one, and not by increasing them with the addition of that which it already contains.

Hospital Reports.

METROPOLITAN FREE HOSPITAL AND FARRINGDON DISPENSARY.

FURTHER CASES OF SYPHILIS TREATED WITHOUT MERCURY.

By Charles R. Drysdale, M.D., M.R.C.P., F.R.C.S.,
AND
Robert W. Dunn, Esq., M.R.C.S.,

A part of which was read at the Harveian Society on March 18, 1869.

(Continued from page 414.)

Case 8.—Seen by Dr. Drysdale. The mother contracted the disease between the eighth and ninth months of pregnancy. The child was born healthy, and remained so. The mother had secondary eruption three months after child was born. A syphilitic child was the result of the next pregnancy. Mother and child, treated without mercury, recovered.

Case 9.—Mother contracted the disease during the last month of pregnancy. A syphilitic child was born. This case was observed by Mr. Dunn. J. C., aged twenty-eight, applied at the Farringdon Dispensary, January 7, 1869. complaining of sores on the privates, and swelling in the groins. First noticed this fourteen days before. As she expected her confinement daily, no examination was made. January 12. Confined of a living child. March 4. Came to the dispensary with the child. She informed Mr. Dunn that since her confinement she had been very ill, and had been ordered not to suckle her child. Syphilitic sore throat observed. Child had no trace of the disease. March 11. She came, saying that the child had caught cold a week ago and that, when watching it, she observed a rash on its face, and that the buttocks were spotted. There was in fact, snuffles, and a syphilitic eruption over the child's body universally, with cracks at the side of the mouth. The husband of this patient first came under Mr. Dunn's care on December 3rd, 1868, for indurated sores on the penis, enlarged glands on the inguinal region. He first noticed the sore a week before he came. Had not had any connexion with his wife since he noticed this. December 10. Sore much better. Said it was quite well and had had connection with his wife during the week. December 31. Roseola; sore quite healed but still indurated. Said that his wife complained of feeling ill. The wife says that she noticed first something the matter with her about the month of December, and thus, if she had even been infected earlier, viz., during the last days of November, the disease would have been contracted during the last two months of pregnancy. If in December, in the last month of pregnancy. M. Diday, in his work on "Infantile Syphilis," says: "It appears that syphilis contracted by the mother, after the completion of the seventh month of pregnancy, has never produced the disease of the fœtus." M. Prieur says "that we have no example of hereditary syphilis, in which the mother was infected during the last two months of pregnancy." M. Ricord says "that until the sixth month, the mother may transmit constitutional syphilis acquired during gestation; but if the infection of the mother takes place during the *last three*, it is not certain that transmission is possible." From the foregoing cases we see that syphilis contracted during the first month is inherited, and that it is as well not to give a decided opinion, that it will not be transmitted, even if the infection takes place in the later months of the pregnancy.

Case 10.—Seen by Dr. Drysdale 3rd April, 1866. Ellen W., three months of age, was brought by its mother to the Metropolitan Free Hospital suffering from eruption, which first appeared at two months of age, and from snuffles. Café au lait stains on chin, and dry eruption on buttocks. The mother has been married to the father two years; is in perfect health, although she suckles the infant. Has not had any symptoms of any suspicious kind since her marriage. This is the first time she has been pregnant. Her husband was ailing, and a brutal fellow, so she has left him. The child recovered in a month, under doses of gr. j t. d. of iodide of potassium in a teaspoonful of water. May 7. Almost well.

Case 11.—Seen first by Dr. Drysdale, 2nd April, 1869. George Guise, ten weeks old, with cracks at sides of mouth, rash on the face, snuffles, dry eruption on buttocks, wizened appearance. The mother of this child, a young woman, aged twenty-one, has had two children; the first of which lived three days, the second is the patient. The mother has never had any symptom of illness since her marriage. Neither sore throat, nor any kind of eruption. She suckles the infant. The child took gr.j. of potass. iod. t. d. and on May 7th was very much better. The father was reported to suffer much from sore-throat.

Case 12.—Seen by Dr. Drysdale 16th April, 1869. E. Carey, aged five months, has had snuffles since its birth. Has eruption on buttocks of a dry kind, and posterior cervical glands enlarged. The mother also in this case did not seem to have been infected, although she was also suckling the child. The child is doing well, on one grain of iodide of potassium thrice daily.

Case 13.—Mrs. Moss, seen by Dr. Drysdale February 16th, 1869. This patient brought with her a child, aged seven years, suffering from the disease described by Mr. Hutchinson as interstitial keratitis, and with the peculiar type of pegged incisors described, and now recognised as signs of hereditary syphilis. The mother, married in 1862, had not had any syphilitic symptoms, and has had two other healthy children after this one. The father had, at the age of sixteen, gonorrhea, but no other syphilitic symptoms that he can remember. He married at eighteen, and his first child was born six months after the ceremony.

These cases seem to indicate, that women certainly sometimes give birth to infected children, without on that account, themselves suffering in their health. It certainly is, however, striking that they do not seem in such cases to become infected by suckling their own children. On the other hand, our note-book teems with cases where the mother having once been infected, there seemed to be no likelihood of her again giving birth to healthy children. Not unfrequently this fact is accompanied by a history of the mother having taken much mercurial treatment.

◆

CARBOLIC ACID IN SCARLATINA.

Dr. A. M. Carpenter says in the *Detroit Review of Med.* I wish to add the weight of my testimony to the beneficial influence arising from the local use of the acid in the Anginose variety of scarlet fever. Not only does it materially lessen the inflammatory process within the fauces, and conduce to the comfort of the little patient, but it prevents in some way, through its action upon the parts, septic poisoning, heals the ulcerated spots readily, and most effectually prevents the viscid faucial secretions from accumulating to an extent sufficient to embarass efforts at respiration. The tonsils, I have observed, resumed their normal tint much sooner after its use, than from any other local agent. Besides, the liability to consecutive abscess and otorrhœa has been diminished in a very marked degree. So, too, does the tendency to serious transudation seem to be obviated, due precaution being exercised against a change of temperature for three weeks succeeding the desquamative stage at which time the liability to renal congestion is greatest. Within the past five weeks I have treated nineteen cases, between the ages of one and ten years, without a single fatal result. In eleven, the febrile movement reached its maximum intensity. Delirium and great restlessness, with stupor, obtained in all these cases—the range of the pulse 140 to 155 to the minute. The heat of the skin was lessened by constant sponging with cool or tepid water and vinegar, iced lemonade *ab libitum*, to allay thirst and soften the parched and swollen tongue, with occasional laxatives, and a solution of chlorate potassa, two drachms to the pint, as a drink, together with the following topical solution to the tonsils twice daily (℞ Acid Carbol. f. ʒss, glycerine, Aq distil. aa. ℥iss, misce) constituted the treatment.

To combat renal congestion spt. nit. dulc. in ten drop doses was relied on. Milk punch and animal essences were freely used when the heat of the skin subsided. The acid assuredly supplies a void long felt by the profession; but let us hope that its value will neither be over estimated, nor the remedy discarded until well tested.

CARBOLIC ACID IN INTERMITTENT FEVER.

Mr. F. C. Calvert reports (*Gaz. Méd. de Paris*, 1869. No. 7) to the Académie des Sciences, some satisfactory results from the use of phrenic acid in intermittent fever, as employed at the Isle of Meurice under the direction of MM. Barranet and Jessier. The acid was used in the first place to disinfect the drains, sinks, and all other sources of miasm. It was then given internally in doses of 0·070 gr., repeated three times a day for the access of fever. Finally it was also employed hypodermically in the dose of three to four centigrammes in twenty drops of water. MM. Barranet and Jessier are of the opinion that these results demonstrate that intermittent fever is due to the presence of animal or vegetable microscopic ferments in the blood similar to those discovered by M. Pasteur.

WEDNESDAY, MAY 26, 1869.

THE LIMITATION OF CONTAGIOUS DISEASE.

AT the last meeting of the Académie de Médecine, M. Leon le Fort, Surgeon to the Hôpital du Midi, has shown, in an elaborate paper, some curious details of the arcana of Parisian life, which are of much interest to those concerned in perhaps the most difficult question of the day—the repression of the extension of venereal disease amongst both the civil and the military, and the application of coercive measures in order to ensure the cure and innocuity of the affected individual. Though suggested, it is hardly possible that legislation can extend to the male population; but with regard to the unhappy class of fallen women, there can be little difficulty, as they pursue a calling so dangerous to the community. There can be no doubt that many "contagion centres" ply their trade with untold detriment, not only to the recipients, but to their innocent progeny. The State loses very many infant lives annually from this taint, and even at a later period manifold evidences of an inherited poison are not wanted.

M. Le Fort's observations extended from November 1st, 1866, to June 1st, 1867, and were carefully conducted, by giving each patient coming for treatment a ticket and number corresponding to a place in the hospital case-book; thus the history was made accurate. It must be remembered that those cases were all *voluntary* admissions or seekers of advice as hospital patients, and represent absolutely but a very small section indeed of those who were contaminated during this period. This section, however, shows 4,070 cases at the Hôpital du Midi alone, and this in a city where energetic measures are taken for restraining the extension of the disease. According to the recognised statistics, these measures have a most salutary effect, as the documents furnished by the "chef du bureau des mœurs" for a period of six years, ending December 31st, 1866, prove that while amongst the women under surveillance, disease was found only as 1 in 7, for a similar period amongst the clandestine who were not under surveillance, the proportion of disease was 1 in 3; but with this difference, that such of the former class as were diseased were at once sent to the St. Lazare Hospital for treatment, the latter remained as "contagion centres," unrestrained and treated as best they could. It is, therefore, not surprising that a large number of the cases of disease presenting themselves at the Hôpital du Midi were derived from the latter source. M. Le Fort draws attention to this fact particularly, as he believes that the greater number of venereal affections in Paris is produced by the class of *prostituées clandestines*, and that some means must be brought to cope with this fertile contagion source. Another remarkable and alarming characteristic amongst the class of *clandestines* is, that they produced the most severe or infecting cases, furnishing half the blenorrhagias, three-fourths of the soft sores, and two-thirds the true syphilis.

A significant fact in favour of limitation, and the effect of treatment in modifying the virulence of the disease amongst the *non-clandestines*, M. Le Fort has given, under special headings, very important details as to the production and source of the disease.

Class No. 1.—The inhabitants of *maisons de tolerance*, who are under surveillance, numbering 1,306, and living in 165 houses; to these were attributed 780 cases of disease.

Class No. 2.—The *fille isolée*, not inhabiting special *maisons de tolerance*; from this class, numbering 2,545, 1,761 cases of disease were furnished.

Class No. 3.—Those that frequent the public balls, 625 cases of diseases were derived from this class, but producing *most* examples of constitutionally infecting sores.

Class No. 4.—Mistresses, or "simples connaissances." These produced 829 cases, including 576 of urethritis, 52 soft sores, and 71 sores followed by constitutional signs.

Class No. 5.—Concubines and "femmes legitimes." These produced three soft sores, 63 blenorrhagias, nine true syphilis.

The total number of the unrecognised he calculates as

being in Paris about	30,000
Filles isolées	2,545
Recognised and in Maisons de Tolerance ...	1,306
Total	33,851

This number, therefore, produced from the recognised "maisons de tolerance" the sum total of 780 cases of venereal, and *one in every seven women* was found diseased, and at once put under treatment, while the other classes produced 3,290 cases of disease. This number may be looked on as very far, indeed, below the mark, as there was no means of restraint or compulsory treatment, and *one in every three women* was diseased, being more than double the amount of disease occurring amongst those legislated for, and compulsorily treated, in the first class. Not only is the diminution of the occurrence of disease well marked in the compulsorily treated class, but what is even more important, the type of the disease is milder, as will be seen on referring to the foregoing tables.

The occurrence of so much disease when such care is taken in its treatment, proves the subtle and persistent nature of the poison, and may well render uneasy those "nomades du plaisir" who make the Parisian capital their rendezvous. What the condition would be, under other circumstances, it is impossible to conceive.

In Dublin we fear the present non-legislative interference causes vast mischief, every practitioner knows the frequency of venereal affections amongst his patients, whether poor or rich, this may be a difficult matter to prove statistically, but there is no difficulty in showing that in a garrison of 4,967 in Dublin, out of 303 men in hospital, 151 are suffering from the disease, in so severe a form as to necessitate their confinement, while numbers suffer from later and slower effects without being compelled to seek hospital advice. It appears from the records of the Westmoreland Lock Hospital, that the infecting sore is prevalent in Dublin, that few escape subsequent contamination, and that many women suffering from this sore continue their mode of life for weeks, causing incalculable mischief amongst all classes.

The number known to the Dublin police, though not under any kind of surveillance, has been—

For 1867 ... 1,047 living in 161 houses
For 1868 ... 967 „ 185 „

This for Dublin represents a large proportion, when it is considered that these are such as absolutely are notorious, hundreds representing the "clandestines" of M. Le Fort are scattered through the city, but all at liberty, when diseased, to pursue an avocation which renders them dangerous not only to the existing, but to the future and innocent, generation.

Though it may be repugnant to our feelings to go the length of continental nations in their efforts to limit the spread of the disease by restraining individual liberty, the good effect of the extension of the Contagious Disease Act has already shown itself remarkably at Aldershot, where statistics prove that, in a strength of 15,000 men, the admissions on account of venereal diseases for the week ending March 12th, 1869, were but 22, whereas, in Dublin, amongst 5,000 men, the admissions for the same period were 49, while, on the 26th March, 1869, the number of men in hospital out of 4,679 was 151 from venereal; when, in addition, the last Parisian statistics show that where no restraint or surveillance is exercised, the proportion of diseased women is one in three, while in the legislated for, it is reduced to 1 in 7. We can conceive no stronger argument for grappling with this social evil, and endeavouring, at least, to restrain the extension of a disease which not only contaminates the recipients for an unknown period, but also their offspring, apart from the more selfish financial consideration of the most entailed by the loss of service amongst the mili-navy—so well shewn by the fact that, from venereal disease alone a number is annually rendered ineffective for an entire week, equalling the whole military force of the United Kingdom, and in the navy, equalling 586 men per day, or the complement of an iron-clad.

◆

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

With the approach of July come rumours as to the election into the Council. Mr. Mackmurdo, Mr. Solly, and Mr. Jno. Adams are the retiring councillors; and there will be at least as many other candidates. Mr. Gay, who nearly succeeded last year, will again offer himself—has, in fact, issued a sort of manifesto, and it is not improbable that Mr. Erasmus Wilson will once more come forward. The names of Mr. Erichsen and Mr. Henry Lee have also been freely mentioned as suitable candidates by a number of the London Fellows. On the other hand, we have heard that the country Fellows have resolved once more to bring forward one of their number, and make an effort to secure a full hearing for themselves. Certainly there are questions on which they should be more fully heard; and we have not the least doubt that many London Fellows would sympathise with them to the extent of giving one vote to their candidate. A meeting of some of those interested is about to be held, and the well-known name of Edwin Hearne will be brought forward as a suitable representative of Provincial Surgery. This gentleman distinguished himself at University College, where he was educated, was admitted a Member of the College in 1842, and a Fellow in 1858, He graduated M.B. at the London University in 1844. and has taken an active interest in medical education and other University questions. He has seen years of general practice, from which, on account of ill-health he retired two or three years ago, and now occupies himself as a consultant in Southampton, where he has passed so lengthy and honourable a career. If a country Fellow is to be elected, there can be no doubt of the wisdom of choosing a man who, like Mr. Hearne, has sufficient time at his disposal, and sufficient interest in the questions at stake to attend regularly to the duties. It would be useless to elect one who could but seldom put himself to the expense and trouble of coming to London. In this respect the gentleman named is peculiarly suitable. His energy has for years found a sphere in work that would prepare him for this, and his deep interest in the matters involved would, we feel sure, lead him to make any sacrifice that might be required. He could afford to attend all the meetings; and we have no doubt, if he consents to stand, that he would undertake to do so.

There are some other things, however, which are of great importance. Although opposed to canvassing, we think every candidate should make a full profession of his faith and his intentions. We have had enough of electing men without pledges. It is no indignity for a prime minister to tell those whose votes he asks the grounds on which he comes forward; and we beg every Fellow to withhold promises and encouragement from every candidate who does not issue an address which will definitely commit him to a policy worthy of his college and his age. Nothing can be more injurious to the interests of the College than that men should govern it who are reluctant to say what principles guide them. A pledge on the many questions that agitate the Fellows should be extorted, without which no vote ought to be recorded.

◆

THE DEBATE AT THE DUBLIN OBSTETRICAL SOCIETY.

We report elsewhere, as fully as it appeared to us to deserve, the meeting of the Dublin Obstetrical Society on last Saturday evening. It appears to be a duty that we should not shrink from a criticism of the method in which the debate on Dr. Evory Kennedy's paper, and notably the proceedings ot last Saturday evening have been conducted. In Dublin there will be no dissentient to our opinion, that neither in respect of the importance of the subject nor the alarming nature of the arguments brought forward by Dr. Kennedy in favour of extern

Maternities, have the time devoted by the society, or the labour expended on the discussion by the various speakers were lost. To decide conclusively as to the truth or falsity of a statement that seven out of eight of the lives sacrificed in Lying-in Hospitals to puerperal fever might have been saved by the adoption of other arrangements, to settle the question beyond cavil, and for ever, would be worth an entire session of the society.

We may be permitted to express, in anticipation alike of the remarks which have yet to come, and of Dr. Kennedy's reply, our doubt that this result is likely to be achieved, or that the professional judgment will be perfectly satisfied that Dr. Kennedy's facts and arguments have nothing in them. In the first place the discussion has seemed to us to take the form rather of an overwhelming organisation for the defence of individual hospitals and for the extinction of Dr. Kennedy, who has ventured to doubt their usefulness, than a disinterested debate on a great sanitary question. We in no respect attribute interested motives to one party or the other; yet we cannot but feel that the falsity of Dr. Kennedy's figures or conclusions is by no means so obvious as to justify in the public mind the simultaneous shout of disapproval with which the Obstetrical Society has received them. We express no opinion on the merits of the question, and we cannot, therefore, say that each and every speaker, or we should say essayist, is not entirely and heartily convinced that Dr. Kennedy is wrong; but we fear that an opportunity has been afforded to cavillers to say that the unanimity of the attack is so suspicious as to invalidate the deduction which may be made from the debate.

This scoff has been strengthened by the form which the debate has taken. In truth, it has not been a debate, but a series of essays, directed with all the calmness of deliberation at Dr. Kennedy, and though probably the value and interest of the proceedings would have lost much by maintaining the custom of *viva voce* discussion, yet we think the reliability of the conclusion would have atoned for the loss, and the dubious colour which the reading of a series of essays has given to the antagonism to extern Maternities would have been less obvious.

No envy will, we feel assured, be felt if we signalise the essay of Mr. M'Clintock as especially free from suspicion. If there ever might have been a bias in the mind of that gentleman it obtained no expression in his paper, and the close reasoning and just conclusions arrived at were commended to the best judgment of his hearers by the entire elimination of the Rotundo-Coombe controversy.

We are compelled to draw a painful comparison between this masterly, eloquent, and acceptable address and that which occupied the society on last Saturday evening for an hour and forty minutes, and of the unfertility of which the brevity of the report in another part of our issue gives testimony. Making every allowance for the latitude of debate, we can hardly find patience for so one-sided and inconclusive an address, and we feel that the wearing out of an entire sitting of the society and of the patience of its members with the cracking of doubtful jokes and undignified anecdotes is one of the abuses to which the method of debate has laid the society open.

It will, in our opinion, be a subject of lasting regret and reproach if this debate goes forth from the society without a word of independent opinion on the matter. We use the phrase with the utmost respect for those who have taken sides against Dr. Kennedy; yet we cannot hesitate to express our feeling that there is much to be said in the view which he has set forth, and that it is hardly within possibility that it can be said perfectly and convincingly by any one man.

◆

SCOTLAND.

THE MORTALITY OF SCOTLAND IN 1866.

We have already analysed the last quarter's return of the Scottish Registrar-General. We have now to report that the twelfth annual return of the same officer is published dealing with the year 1866 as a whole. That year was noteworthy, as our readers will remember, for the prevalence of epidemic cholera and fever. The cattle plague was also rife. We therefore turn with interest to the returns, now that they are at length completed, and find as might be expected, that the mortality was high, although in other respects the year is a favourable one.

There were according to this return 71,348 deaths registered in Scotland during the year 1866, being at the rate of 22·63 deaths in every thousand persons in the estimated population. This was a death-rate considerably above the mean of the eleven previous years, which was at the rate of 21·46 deaths in every thousand persons.

In England, during the same year, the deaths were in the proportion or 23·61 in every thousand persons, being considerably higher than the mortality in Scotland, though below the English average, which was in the proportion of 22·24 deaths in every thousand persons.

The insular and mainland-rural districts had, as usual, a much lower mortality than the town districts. Thus, 2,664 deaths occurred in the insular, 34,314 in the mainland-rural, and 34,372 in the town districts; which indicates a mortality of 16·87 deaths in every thousand persons in the insular, 19·16 deaths in the mainland-rural, and 28·51 deaths in every thousand persons in the town districts.

Of the eight principal towns in Scotland, the mortality was highest in Dundee and lowest in Perth. Thus, of every thousand persons in each of these towns, there died during the year 22·8 in Perth, 24·3 in Leith, 27·5 in Edinburgh, 28·3 in Paisley, 29·8 in Glasgow, 31·0 in Greenock, 31·1 in Aberdeen, and 32·0 in Dundee.

As in former years, males died in higher proportions than females, seeing that in every thousand of each sex 23·74 males died, but only 21·63 females. The average of the ten years 1855-1864, shows that in every thousand of each sex there died annually 22·38 males, but only 20·41 females—a circumstance which of itself would go far to account for the increasing number of females in the population, even without taking into account the known fact that a much higher proportion of males than females emigrate to the colonies and America.

Table XXV. shows the striking fact, that at every consecutive period of life from birth to the 90th year, males died in higher proportions than females during 1866, with the single exception of children between the fourth and fifth years of age. Thus, during the first year of life, 16·200 per cent. of males died, but only 13·607 per cent of females. From birth to five years of age, 6·347 per cent. of males died, but only 5·70 per cent of females. From twenty to thirty years of age, 1·119 per cent. of males died, but only 0·928 per cent. of females. From forty to fifty years of age, 1·723 per cent. of males died, but only 1·442 per cent. of females. From sixty to seventy years of age, 4·441 per cent. of males died, but only 3·637 per cent. of females. At all ages, therefore, from birth to burial, the tendency of the male to death is greater than that of the female, and at no age was that greater tendency of the male to death more strongly shown than during the first year of life, when out of every thousand of each sex, 162 males died for every 136 females.

It is very instructive to compare the mortality, at each corresponding quinquennial period of life, in the mainland-rural and town districts, inasmuch as it proves, more forcibly than

any mere statement could, the greater waste of life which is attendant on a residence in a town. This destructive agency of the town on human life is not confined to any particular age, but extends to all ages and to both sexes. Thus, to instance a few examples, in every thousand males living under five years of age, there died 48·00 in the rural, but 90·60 in the town districts. From five to ten years of age there died 7·88 per thousand in the rural, but 12·68 in the town districts. From fifteen to twenty years of age, 6·87 per thousand died in the rural, but 8·99 in the town districts. From twenty to thirty years, 9·58 per thousand died in the rural, but 12·91 in the town districts. From forty to fifty years of age, 12·58 per thousand died in the rural, but 24·66 in the town districts. From sixty to seventy years of age, 36·14 per thousand died in the rural, but 65·97 in the town districts.

◆

Notes on Current Topics.

Samaritan Free Hospital.

On the Sunday after Ascension the Rev. J. W. Reeve, of Portman Chapel, preached two sermons, morning and evening, on behalf of the Samaritan Free Hospital. The preacher put forth the claims of this deserving charity in brief but forcible language, appealing to the published statistics of the hospital as the surest evidence of the good it was doing. The two collections amounted to the very handsome sum of upwards of £106.

University of London.

In the new examination for women, a list of successful candidates has been issued. The following is the honours division:—Louise Hume Von Glehn, private study; Sarah Jane Moody, private tuition; Eliza Orme, private study; Kate Spiller, private study; Isabella De Lacy West, Bedford College and private study; Susannah Wood, Ladies' College, Cheltenham.

Arsenic Poisoning at Wurtzburg.

Nearly 400 persons have narrowly escaped poisoning at Wurtzburg, a short time ago, by eating bread in which half a pound of arsenic had been accidentally introduced. The fatty matter with which bread was commonly eaten, such as milk and butter augmented the solubility of the poison, and consequently the graver symptoms of poisoning which are due to its slow absorption were rare. There was no case of death, but all the consumers of the bread were more or less seriously attacked.

Diagnosis of Cancer by the Microscope.

At the last meeting of the Pathological Society, on May 18th, Dr. Dickinson exhibited drawings of cells of encephaloid cancer that he had made from masses, looking like clots of blood that had been passed by the urethra.

The patient was a gentleman in excellent health, but annoyed at times by finding himself passing small lumps of clotted blood by his urethra. Some of these were brought to Dr. Dickinson, who, on examining them, detected cancer cells and declared the patient to have cancer in the urinary organs. This idea was at first utterly discredited, but by the end of two months the patient's distress had increased greatly, his general health had broken down, and he died, as was admitted, with every symptom of cancer of the bladder, although it was impossible to get leave to make a *post-mortem* examination.

In commenting on this important case Dr. Dickinson remarked how often he had sought in vain for the true cells of cancer in the discharge from cancerous sores; as for example, in the discharge from the vagina in cancer of the uterus. The cancer cells seemed to be destroyed in the discharge and so could not be detected.

So far as our own experience in these matters goes, we remember once to have found what seemed, to a most able microscopist and pathologist, true cancer cells in the expectoration from a case of throat cancer fatal shortly after, and which had got to the ulcerative stage when the examination of the expectoration was made. Prior to ulceration and disintegration of cancer it is not very probable that cancer cells will be found in any matter discharged spontaneously from the diseased surface.

Elevated Regions for Consumption.

At the last meeting of the Medico-Chirurgical Society, Dr. Weber read an able paper setting forth the advantages to be derived from prolonged residence in elevated climates. He showed how mistaken is the popular notion that cold is injurious to the consumptive, and following in the wake of Archibald Smith, Mühry, Hirsch, Jourdanet, and others accepted the doctrine that the sea-side resorts are not nearly so valuable as those of lofty regions. This doctrine has been rapidly growing lately, and some of our most able men would rather select mountainous districts where the cold of winter is severe, than let their patients go to the shores of the Mediterranean, or the valley of the Nile. Dr. Weber's conclusions on the question were as follows:—

1. That the elevated regions deserve greater attention in the management of consumptive tendencies and affections than they have hitherto received.

2. That they deserve this attention not only as summer, but even more so as winter, health resorts.

3. That without under-rating the value of maritime and other low-level health resorts, the elevated localities offer great advantages in case of early consumption and tendencies to consumption, in the disposition to catarrhal pneumonia, and the results of this disease, particularly the so-called tubercular (cheesy) deposits, and tubercular (pneumodic) infiltrations.

4. That in such cases the occurrence of fresh catarrhal and other acute intercurrent affections appears to be less frequent in high-level than in low level health resorts.

5. That the tendency to absorption and fibrous transformation or cicatrisation of deposits is promoted, and the tendency to the breaking down of tissues and formation of cavities is counteracted in elevated health resorts.

6. That the tendency to hæmoptysis is diminished, and not, as usually stated, increased, in elevated localities.

Dr. Weber concluded his paper with a tribute of gratitude to the late Dr. Archibald Smith, to whom he is indebted for much valuable information on medical climatology, especially with regard to elevated regions.

Railway Travelling.

Some statistical investigations of Dr. Wiegand, of Hallow, based upon the reports of thirty-eight companies, have been published, and the results for 1868 are as follow:—Of 11,125 engine drivers, stokers, and other officials travelling with the train, 119, or 1,072 per cent., died; while of the 43,853 other officials employed only 408, or 0,831 per cent., died in the same period. The rate of mortality is thus somewhat higher in the first than in the second class, though the difference is not enough to show that the occupation is more than usually unhealthy.

Royal Medical Benevolent Fund Society of Ireland.

The Annual Distribution of the Funds of this most admirable society will take place early in June, and at present the Central Committee meet two or three times every week for the purpose of considering the various applications for assistance from members of the Profession and their widows and children. At the last meeting the Treasurer (Dr. James Little) reported that since the 1st of March he had received the following sums :—

Subscriptions paid in Dublin	£ 74	2	0
Wicklow Branch per Dr. Nolan . . .	6	10	0
Sligo Branch per Dr. Lynn	6	10	0
Londonderry Branch per Dr. Babington . .	24	0	0
Clare Branch per Dr. Molony	10	8	0
Cavan Branch per Dr. Mease	7	1	0
Tyrone Branch per Dr. Thompson . . .	17	0	0
Belfast Branch per Dr. Browne . . .	69	0	0
Executors of late Dr. Frith, of Limerick . .	100	0	0
Interest on Investments per Dr. T. F. Duncan .	183	8	4
Donation from Dr. John M'Donnell, Dublin .	5	0	0

The Pharmaceutical Society's Conversazione.

The rooms, of the Pharmaceutical Society, Bloomsbury Square, were on the 18th inst., thrown open, in order to receive its members and its guests at the Conversazione. There was a large attendance, and the arrangements were complete and satisfying to all.

Objects of scientific and of general interest were displayed, together with the newest and rarest pharmaceutical preparations ; including, turacine (extract from the coloured feathers of the Corythaix albocristala) ; Targonium lakes, obtained from coal-tar. A salt produced by a chemical change effected in morphia, called Apomorphia, &c., &c.

Royal Society of Medicine.

It seems that the Amalgamation Scheme will be carried out, but we regret to find an indisposition on the part of those interested to modify such defects as discussion has brought out. The Medico-Chi or those who rule it, appears to have lacked the courage to take the bull by the horns and bring about what was wanted. They have therefore, tied themselves to certain other societies, in the hope by their aid of accomplishing what they desire. On the other hand, other societies, older,more numerous and more powerful, are quietly ignored. Unless some administrative genius arise we fear the change will be of little service. The mere putting a bandage round the separate limbs is not calculated to give new energy to the body.

Hospital Management.

We are assured that our late remarks have hit a blot in the management of Hospitals and Medical Schools. The public is as deeply interested as the profession in putting down the ridiculous rivalry that has produced so much waste of power and money. If the minor hospitals and schools of medicine persist in exclusive rules to gratify an inordinate vanity, there is but one way of terminating their jealour frenzy. By the mere force of their own folly they must be extinguished. The larger and more important charities must be supported—they will never be deserted by the public. Those too small to act uprightly, and only large enough to diminish the prosperity of the best must either be swept away altogether, or amalgamated with the largest centres of charity and instruction.

Charges of Assault Against Medical Men.

A case has been somewhat imperfectly reported in the papers, in which a verdict of £20 has been given as damages against a police-officer and a surgeon for an assault. The offence was committed by the making of an examination, with a view of ascertaining whether there had been recent delivery, the woman being charged with concealment of birth. It should be remembered that a medical man has no right whatever, to press any woman to submit to such examination. A doctor is not a public prosecutor, nor does it redound to his honour to assume such functions. He has no business to be seen in such affairs, except in the character of a medical witness, and as such his evidence should be impartial. How can it be above suspicion if he have taken apparently a side in the matter. It would be better always to refuse to be mixed up in such a case, *except at the request of the patient*, than to run the risk of a charge of assault, or let the professional man appear in the light of an informer.

Intern and Extern Maternities.

The debate at the Dublin Obstetrical Society on Dr. Evory Kennedy's paper was resumed on Saturday evening last, and created even greater interest and attracted a larger attendance than on any former occasions.

Dr. Sawyer, professor of midwifery, in the Royal College of Surgeons, opened the debate, and occupied the entire sitting in a jocular address in which occasional reference was made to the subject in debate. He said that he felt that the statistical argument of the question had been so thoroughly exhausted by previous speakers that he should not attempt to follow it. He admitted " that isolation of parturient women is one of the most desirable objects which could possibly be achieved," but conceived that the practical difficulties of Dr. Evory Kennedy's scheme were insuperable.

He exhibited a statistical return of the deaths which had occurred in the Coombe Hospital between the years 1861 and 1869, from which it appeared that out of 3,798 cases of labour fifty had died, or one in seventy-six, and of these thirty-three were from metria, and seventy-one from other causes, twenty-one of the whole number having been operated on. Dr. Sawyer proceeded to detail the circumstances of each case with the view of showing that many of them were not justly chargeable to childbed mortality. He concluded by reading a lengthy letter from Mr. Ferguson, of the Veterinary Department, respecting the influence of zymotics in the lower animals.

Dr. Sawyer's address extended beyond the usual hour of adjournment, and it was therefore necessary to postpone further debate until next Saturday, when Dr. Beatty, ex-professor of midwifery in the Royal College of Surgeons, will open the discussion, and the debate will probably be concluded. Dr. Evory Kennedy will not reply until the following Saturday evening.

The Health of Dublin.

In the Dublin Registration District the births registered during the week ending May 15th, amounted to 171. The average number in the corresponding week of the years 1864 to '68 inclusive, was 178. The death registered during the week were 120. The average number in the corresponding week of the previous five years was 147. The deaths from scarlet fever amounted to six, showing a decrease of eight as compared with the preceding week. Two deaths were referred to typhoid or enteric fever, and a like number to simple continued fever. Four deaths were referred to convulsions: the average number in the corresponding week of the last five years was ten. Bronchitis caused thirteen deaths, and pneumonia four. Six deaths were ascribed to paralysis, and two to apoplexy. Diseases of the heart proved fatal in ten instances, carditis and aneurism in one, respectively. Phthisis was the cause of twenty-two deaths. Five deaths were caused by liver disease, and one by jaundice. Nephria or Bright's disease caused two deaths.

Dr. Stevenson, the medical officer of the St. Pancras Vestry, in his report to that body, says that what are called "preventive diseases," such as scarlatina, typhoid fever, and small-pox, might have been very much reduced in their effects if some proper provision had been made by the vestry for the disinfection of clothing, &c. Of the three diseases above specified, 371 persons died in St. Pancras in 1868, and from fever 122 deaths occurred.

Professor Lister's observations on the Ligature of Arteries on the Antiseptic System have been issued in the form of a very beautifully got-up pamphlet, by Messrs. Edmonston and Douglas. There are three engravings. 1. Constituents of incipient abscess around the remains of silk ligature, 500 diameters. 2. Vessel, longitudinal section of diseased. 3. Some elements of fibro-plastic stricture of organized peritoneal ligature, 500 diameters.

The following Hospitals and Medical Charities have become entitled to legacies and bequests during the past week:—The Devonshire Hospital, a bequest of £250, by the will of the late Wm. Gibson, Esq.; the Royal Free Hospital, London, £100, by the will of the late Miss E. S. Kemp. By the will of the late S. Bostock, Esq., of the Stock Exchange, the Middlesex, King's College, University College, London, and the Seaman's Hospitals, each become entitled to £5,000, 3 per cent. annuities. The South London and Surrey Dispensaries also receive £1,000 each in stock, The Nottingham Hospital has not been forgotten by an old in-patient, Frederick Attenborourgh, formerly a private in the 3rd Dragoon Guards, who has recently died and bequeathed the whole of his savings (£4,200) to this Hospital as a mark of gratitude for kindness and skill bestowed on his case some fifty-three years since.

The eighth report of the Glasgow Dispensary for Skin Diseases, has reached us:—During the last twelve months, the number of new cases treated was 1,089; the total number since the foundation of the Dispensary in 1861, being 8,695.

Of these 8,695 patients, 3,406 were more or less of a contagious nature; and as almost all of them were cured, some idea is conveyed of the usefulness of the Institution in checking the spread of contagious disorders.

The number of students enrolled since the commencement of operations, has been:—1861, 1; 1862, 30; 1863, 20; 1864, 17; 1865, 41; 1866, 33; 1867, 34; 1868, 42; or 218 in all; and as this attendance is purely voluntary, it affords conclusive proof of their belief that the grouping together of certain classes of diseases in special institutions, affords instruction such as cannot be obtained in a general hospital.

The Dispensary is open once a week for the treatment of Aural Diseases. Last year 270 patients, representing 288 diseases of the ear, were treated.

◆

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

April 16, 1869.

(Continued from page 427.)

George H. Porter, Esq., M.D., President of the College, in the Chair.

Upon the 2nd March there was another relapse without any appreciable reason. At five p.m. I was sent for, and found him moaning and low, the pulse thready, in fact, almost gone. He was rallied by brandy and aromatic spirit of ammonia. At ten p.m. he was worse, the nose and face were again cold, the hands dropped over the side of the bed, and pulse barely perceptible at the wrist. He was gulping air, and borborygmi were audible in the bowels.

He was immediately given a lavement of two ounces of brandy with four grains of quinine and six ounces of strong beef tea.

Upon the 4th the bowels were discharging large quantities of black fœtid pultaceous matter, almost without appreciation by the patient, but still he could not be altogether regarded as passing involuntary stools. Upon the 5th he was removed into an adjacent large and airy room facing the south-west, so as to have the full benefit of the sun, and full support by day and opiates by night were continued as before; and he progressed favourably, with the aneurism decreasing daily in size until the 10th, when the extract from my note-book is as follows:

"Doing very well; taking food and feeling strong. The discharge, though large in quantity, healthy; and the urinary secretion normal. Patient taking twelve grains of quinine and two scruples of saccharated iron with half a bottle of Madeira daily, and a considerable quantity of essence of meat and brandy, also oatmeal stirabout for breakfast, which he eats with relish. Sleeps soundly under twenty-five minims of black drop; is 'self-confident and cheery.'"

Upon the evening of that day, a few hours only after such a promising condition being recorded, hurried respiration set in almost suddenly, with failing pulse and debility as before. No cause could be assigned for this change. To the stimulants now employed his system failed to respond, and he died quietly upon the 11th March, the twenty-first day after the operation.

The *post-mortem* examination was made twenty hours subsequent to death. The aspect of the body was very pale, but not of a bilious tinge, and the abdomen was somewhat distended by air. There was superficial lividity of the ends of all the toes upon the ligatured side, and a vibex containing purplish serum upon the heel of the same foot.

The wound in the abdomen was partially united below, but open towards its upper angle to the extent of an inch and a half, constituting the aperture through which, during life, the profuse discharge referred to had taken place. This opening led into a pocket-like cavity, extending upwards and downwards for twelve inches, and passing for some distance backwards, being formed between the integuments of the side and the muscles and parieties of the chest, which were dissected bare, the cellular tissue uniting these structures having all broken down and degenerated into pus, under the diffuse inflammation, to an extent corresponding to the space limited by the strapping with adhesive plaster. The walls of the abdomen, upon being incised from the ensiform cartilage to the pubes, presented a mass of yellow fat, quite in excess of what might have been anticipated from inspection of the patient during life or of the body after death, and now accounting for the unusual quantity met with during the operation. The hollow viscera were all perfectly healthy, and there was no trace of peritoneal inflammation throughout the intestinal tract.

Upon removing the viscera from the abdomen, the aorta and the common and internal iliac arteries upon the right side were found healthy in appearance and natural in colour; but the external iliac resembled a vein, being filled above and below the site of ligature with semi-fluid, black-coloured blood, extending as high up as the bifurcation, and downward as far as the commencement of the aneurismal sac.

Upon tilting up the artery it was found to contain nothing but a little dark semi-fluid blood; no fibrine plug, such as would be necessary for occlusion of the artery and suppression of hæmorrhage, existed either in the cardiac or the aneurismal side of the ligature. The heart was small in size, but loaded with external fat, whilst in structure it was so soft that the finger passed without resistance through the substance of the left ventricle. The aorta, above the origin of the semilunar valves, and for some distance downwards, was the subject of atheromatous deposit. Both kidneys were enveloped in fat and very soft, with the capsule of each peeling off most readily. Upon removing the sac of the aneurism from its site in the femoro-inguinal and adductor region, there was not any erosion of either the pubis or femur, or injury from pressure upon the capsule of the joint.

I feel, Mr. President, that I have been tedious in detailing this case; but I know that in this society, where everything relating to the treatment of aneurism has been so certainly determined through the patience with which the subject has been investigated by its members, that I shall be pardoned, and my concluding observations shall be brief.

The cast, the drawing, and preparation, are all before you, and speak for themselves.

The disease will be seen to have originated in consequence of fatty degeneration, and the same reduced condition of the system prevented recovery, and indirectly led to death.

That pyæmia, or suppurative fever, was the immediate cause, is undoubted, but, had the patient survived longer, and lived until separation of the ligature took place, death from profuse secondary hæmorrhage must have instantly ensued, for there was no barrier whatever between the ligature and the heart, and nothing to prevent the collateral circulation pouring out its blood through the patent epigastric and circumflex ilii arteries into the wound.

In recording the treatment from day to day I have dwelt at length upon the dietary and stimulants given, as well as the medicines prescribed, together with the supply of pure air and oxygen and sun afforded to the individual, in order to show how fully his system was supported, and how totally the ordinary elements favourable to blood poisoning were absent, and yet death from CONSTITUTIONAL tendency supervened.

The practical point to be adduced from the consideration of this case is the treatment to be adopted in any similar one that may occur.

Supposing that after a full and fair trial by compression, such as was in this instance adopted, consolidation of the aneurism does not follow, is the ligature to be employed without further preface? I would say no; but, in accordance with the suggestion of Doctor L'Estrange, that venesection to the extent of a few ounces should be adopted for the purpose of testing the crassamentum, and thereby the condition of the blood, and that if the blood remains semi-fluid, tarry, and black, then that the taking up and tying of the vessel with a ligature should not be resorted to, but that the clamp lately introduced by Mr. Porter should be placed upon the vessel for forty-eight or seventy-two hours, and then removed. All that the ligature can effect towards the production of consolidation of the contents of the sac is thereby produced, and if the blood will not solidify, then no injury is produced upon the vessel when arrest of circulation has been made, its coats, as experience has proved in Mr. Stokes's case, being neither cut nor influenced in any way that would lead to the production of secondary hæmorrhage, so that the patient, apart from the immediate effect of cutting down upon the vessel, is in exactly the same condition as prior to the operation.

The injection of perchloride, or other preparations of iron into the sac, as well as the practice of galvano-puncture, have been so generally fatal, that I should hesitate in yielding to the wishes of the patient or his friends before adopting either, and should not recommend its adoption.

The PRESIDENT was sure the society would agree with him, that rarely had a more interesting or practical case been brought under their consideration than the one just read by Mr. Tufnell. It was a subject that would always be interesting to Irish surgeons. He took that opportunity of thanking Mr. Tufnell for his kindness in permitting him to see the case when it was being treated by compression; when he deligated the artery, and when the *post-mortem* was being made. The point referred to by Mr. Tufnell, and first suggested by M. L'Estrange, was one well worthy of deep consideration namely, the examination of the blood in these cases. They found that some cases of aneurism when treated by compression, would get well in a few hours; while in others no matter how perseveringly treated there was no tendency in the blood to coagulate in the sac of the aneurism, and if they gave up compression and adopted the ligature the same thing exactly occurred. It might therefore be well worth trying by a close chemical or microscopical examination of the blood whether some means might be found of placing that fluid in a condition favourable to coagulation.

Mr. STAPLETON said they were all deeply indebted to Mr. Tufnell for the lucid manner in which he had explained this interesting case. There did not appear to have been any examination of the blood in all operations. He had seen men with cavities in the lungs operated on and live for years afterwards, but if a patient had albuminous urine the surgeon would probably fail in having successful results after his operations. The urine therefore, should be attended to above all things. Mr. Tufnell thought this man died of suppurative fever. That was a wide term, but he (Mr. Stapleton) did not think the man showed any symptom of it. The great symptom of suppurative fever was that it was always ushered in by intense rigors followed by profuse sweating, and accompanied sometimes by an eruption. He would look on the present case as one of diffuse inflammation occurring in a man affected with Bright's disease of the kidneys. That was quite a different thing from a man having suppurative fever or pyæmia. No doubt the disease which, in his opinion, caused the man's death was a sort of low inflammation or diffuse cellulitis resulting from a blood poison. He had seen several cases of phlebitis, and he found that the inflammation took place external to the vein. He had a case in Hospital where the saphena vein was as thick as his little finger. The man had been put on mercury, salivated, leeched, and treated in a variety of ways. He (Mr. Stapleton) treated him with the muriated tincture of iron, and nourished him. He had seen abscesses occurring outside the vein, and had seen them ulcerate near the vein, and in this way pus has been carried into the circulation. In suppurative fever the blood during life was more than ordinarily coagulable, whereas after death it was peculiarly fluid. If this man had pyæmia, his blood would be in a more coagulable state and there would have been some attempt at coagulation.

Dr. MAPOTHER thought as in cases of aneurism it sometimes happened that the greatest care and skill failed to produce any clot in the artery, this might probably depend on the state of the blood, and therefore he thought the suggestion thrown out by Dr. L'Estrange was of the greatest possible value. No doubt the examination of the urine was of great value, but he always thought the most important fact to determine, with regard to the urine in Bright's disease, was not the presence of albumen but the relative want of urea in it. If for instance, but one-third of the normal amount of urea was found in the urine of a man suffering from an aneurism, there would be evidence that the remedy ought to be directed to the blood with a view to bring it to such a state as would be favourable to coagulation. With regard to the case of aneurism he was of opinion that it must be produced by total stoppage of the circulation to cause coagulation. It was desirable he thought to keep the sac as full as possible, and perfectly still. Coagulation of the blood depended on the going off of the volatile matter which it contained, and therefore it was important that no fresh blood should be allowed into the artery. The sac being kept full and perfectly at rest coagulation would occur in it just as it would if the blood were removed from the body.

The **President** asked Mr. Tufnell how much blood would he take for the purpose of examination.

Professor **Macnamara** asked, did Dr. Mapother think it essential to occlude entirely the current of blood to succeed in curing the aneurism. He should be sorry to agree with him, for he had seen cases in which the blood was never entirely coagulated, in which a small current of blood continued to pass through the tumour, and these were among the most successful cases he had ever seen. Although it was desirable to occlude the blood entirely, he could not subscribe to the doctrine that it was essential. The whole world looked to Dublin as the centre from which was to come all that was known of the treatment of aneurism by compression. It was remarkable that in other places they did not succeed in that method of treatment as they did in Dublin. He remembered speaking to Mr. Paget on the point, and that gentleman wound up by saying that the Dublin surgeons seemed to understand this subject better than it was understood elsewhere. He repeated that he should be sorry to hear it laid down as a *sine qua non* that success in the treatment of aneurism by compression was due to the complete occlusion of the sac.

Dr. **Hewitt** referred to the advantage of the clamp recently introduced by Mr. Porter over the ordinary ligature. The latter produced total disruption of the inner coat of the artery whereas Mr. Porter's apparatus produced no abrasion of the internal, middle, or outer coat. A slight paleness of the internal coat of the artery was the only effect produced by the application of Mr. Porter's clamp; and he hoped the instrument would receive further trial at the hands of the profession.

Dr. **Darby** said he had heard that evening much that was new and interesting. As to coagulation of the blood he remembered, when a student in the Richmond Hospital, hearing Peele say with respect to a patient suffering from purpura hæmorrhagica who had been given up by the surgeons as hopeless. "Bleed him my dear, it is the only chance; it will cause coagulation of the blood. If you dont get coagulation of the blood he will die, but if you bleed him you will produce a disposition to coagulate for the blood is a living fluid." The late Dr. Macartney always impressed on his class that the blood was a living fluid; and at that time people did not talk about chemistry and the microscope as they did now. He had heard Mr. Abraham Colles say, "If you dont get blood to coagulate in the treatment of aneurism you can't cure it." Mr. Tufnell had happened to get one of those unfortunate cases that nothing could have saved. He (Dr. Darby) had tried bleeding in another case. He never saw so bad a subject. The man was fifty years of age, pallid, said to be dropsical, of relaxed fibre and bleeding to an enormous extent. He recommended the man to be bled and he was bled four or five times, and recovered from acute hæmorrhagica. That, however, was in the days when bleeding was prevalent.

Mr. **Tufnell** in reply said, there was nothing in the appearance of the urine or in the other symptoms to lead one to suspect disease of the kidneys; and although they were very fatty he thought if the urine had been examined it would have been found to be healthy. There were no rigors, no sudamina, but there was chilliness. As to what Dr. Mapother said about stoppage of the circulation being necessary, he should like to stop it completely, but in the thoracic and abdominal aorta it was not always possible to do so, nor was it always desirable. He had heard of a case of double thoracic aneurism, when death was caused by the aneurism being cured. The man lived as long as the main current was fluid, but when the tumour became solid it pressed on the trachea and caused death. In another case which could be seen in their museum, an aneurism, unsuspected during life, was found after death to have been cured, in consequence of the state of quietude in which the patient had been kept. The individual had been obliged to lie quiet in consequence of ascites, and rest favoured coagulation and cure of the aneurism. He could have thought six ounces of blood would be the utmost that ought to be taken from the patient for the purpose of testing it, but from the practical observations of Dr. Darby there might be no harm in exceeding that amount. He considered that with a view to fibrinization it was not necessary to have direct occlusion of the vessel.

STRANGULATED FEMORAL HERNIA.

Dr. **Darby** read the following case:—John Martin, aged sixty-seven years, was admitted to the Rathdown Infirmary, on the night of the 26th March, 1869, complaining of constipated bowels, vomiting, and cramps. He had a turpentine enema which was followed by a copious solid feculent evacuation. 27th. Eleven o'clock, a.m., I first saw him, and found he had a suffused anxious expression of face, hot skin; furred dry tongue; could not feel pulse at wrist; but found it 90 in the left femoral artery. The abdomen was tumid and tender on being pressed, a tumour the size of a walnut was discovered in the right groin, it was not painful or tender to the touch. Considering it to be a hernia, I endeavoured to reduce it by taxis, without effect. He bore the manipulation without complaining of pain. He stated that some years ago the late Dr. Hutton had told him he had a rupture, and had advised him to wear a truss, but that as the "lump" had not been at all troublesome, he had never applied a truss. However, he stated that on one occasion he had laid down, and put up the "lump" with his own hands. He further stated that on Wednesday, 24th instant, about forty-eight hours before admission to Hospital, he had, while lifting a heavy weight, felt pain in the tumour, and became faint, and shortly afterwards vomited. These symptoms increased to the time of my visit. At six o'clock, p.m., I opened the sac, found it to contain omentum attached to the sac throughout its whole surface by old membranous adhesions. I passed my finger completely round the protrusion, tearing up those adhesions, and introducing a director into the ring, carried it round the strictured neck, and then little by little, I, with my fingers returned the protruded omentum completely into the abdomen, dressed the wound and gave him thirty drops of laudanum, with directions to repeat the dose in six hours if he did not sleep.

It is not necessary to occupy the society with details of symptoms and treatment further than to say that on the 29th he passed flatus per ano, refused to take the opium draughts, or calomel and opium pills ordered; that turpentine fomentations were applied frequently, and poultices constantly to the abdomen; that he had a shaped natural stool on the 30th, without any purgative having been adminstered either by the mouth or the anus; and that he died on the morning of the 31st.

A *post-mortem* examination showed that the protruded part had been fairly returned, that the wound was in process of healing, that no trace of peritoneal inflammation was observed; but that extensive enteritis existed, the whole tract of the intestinal canal being covered with enlarged arborescent vessels, was of a deep rose colour, with occasional patches of deep red, and a portion of the ilium was thickened, contracted, and nearly black. This portion I produce, and although it has lost the contracted condition, and to a great degree the dark colour, it still retains sufficient of those characters to enable you to perceive that gangrene, if not actually present, was not far distant.

My reason for trespassing on the time of the society with this single case is, that it exemplifies even more strongly than did those cases brought under the notice of the Surgical Section of the British Medical Association by me at Oxford last August, the practicability of reducing strangulated hernia without dividing a single tendinous fibre, and that it affords a more confident hope that it will be found by other surgeons to possess the great advantage of rendering a difficult and dangerous operation more simple and more safe; and that hereafter the reproach of having in any degree contributed to the formation of those enormous and irremediable protrusions which have hitherto occasionally resulted from the too free division of those tendons shall not attach to any members of our profession. I cannot conclude this paper without informing the society that on a recent occasion, when Mr. Stokes brought a case of strangulated hernia under your notice, my much lamented friend Mr. Maurice Collis, whose untimely removal from amongst the distinguished surgeons of Dublin, I, in common with all who had the privilege of his acquaintance, deeply deplore, informed me he had a short time previously operated for strangulated hernia, in the North of Ireland, without dividing the stricture; and that the case had terminated so favourably and so much to his satisfaction, that he should in future adopt that mode of operation.

Mr. W. **Stokes** observed that he attended at the Richmond Dispensary during the distribution of trusses, and saw all the cases of hernia which were presented there, but he had not seen any of those cases of large extrusion of the intestines to which Dr. Darby alluded as a consequence of a too free division of the tendinous structure. He did not think such cases were very common, and when they did occur the fault was that of the operator and not of the operation. They had to elect between one of two evils—the division of the peritoneum, and the division of the rings. It was a fact that a vast number of these cases could be reduced without dividing any fibres. They should, therefore, always endeavour to effect that object in the first instance, and if it became necessary to divide the fibres they should divide as few of them as possible.

Mr. **Stapleton** said if the hernia had been down for any time, the danger was that the tendinous parts might cut through the peritoneal coat of the intestine and if the least force was used in attempting to reduce the hernia, the intestine became ruptured. In a case under his care the hernia had been down for a week; the stricture was divided, and the hernia reduced, but in four days afterwards the man had a violent fit of coughing, and the intestine gave way where the peritoneal coat had been divided by the pressure. The greatest caution was therefore necessary in manipulating the parts in those cases where the strangulation had existed for several days, and when the operation of dividing the stricture had been resorted to.

Dr. **Darby** in reply, said he wished some of his friends in Dublin would try the mode of operation which he recommended. He could assure Mr. Stokes, that old practitioners like himself, did sometimes meet with cases where the operation had been in fault. All standard works on the subject are against dividing much of the stricture, but the most careful operator might sometimes divide more than he intended; and the division of the stricture embraced the whole of the important steps in the operation. Any man who was at all careful could open the sac, and he advocated the opening of it for that reason. He had no fear of peritonitis as the result of that operation, and as a matter of fact peritonitis was not the usual cause of death in these cases. In the whole course of his experience he remembered only one or two cases in which peritonitis had followed the opening of the sac. Death in these cases resulted from a variety of causes, intense enteritis, paralysis of the bowel, &c. As to the tension of the edge to which Mr. Stapleton referred, it existed in every case, and it would be a bad thing if it did not. He had operated a good many times for strangulated inguinal hernia, and on looking back over them all, he thought there was not one which might not have been reduced without dividing the stricture. He had operated twenty-four times altogether, and up to the last seven cases he had always divided the stricture. The tendinous stricture once divided was never repaired, and if the opening were made too large, an injury was inflicted on the patient from which he would never recover. He therefore avoided dividing the stricture in these cases, and adopted the operation of opening the sac.

The meeting then adjourned.

Literature.

SEWAGE.*

Among the numerous questions clamorous for answer in the present day are, what to do with our criminals? and what to do with our sewage! In both cases we have to deal with the refuse and off scourings of humanity; but, as we cannot deal with each exactly on the same principles, we will leave the first to the care of those who fondly imagine they can do great things by an appeal to moral feelings long since extinct, and proceed to draw attention to the useful little pamphlet of Dr. Simpson, on the sewage question now before us.

Commencing with a short notice of the views that have already been put forward, and after alluding to the dangers and disadvantages of imperfect drains, Dr. Simpson refers, on his 5th page to Dr. Hawkesley, and his pamphlet in favour of the dry earth system, as being so valuable in saving manure as well as in preventing the pollution of rivers and water courses by liquid sewage.

In China, where the dry earth system is carried out in great perfection, all human excreta being removed twice a day, and mixed with earth, it appears that "the soil for upwards of three thousand years has never decreased in fertility, the fields yield a crop twice a year and never lie fallow." This is because in China they return to the soil the matter taken from it instead of pouring them away to waste and thus the soil does not become exhausted.

It appears that so far as the dry earth plan of sewage, invented by Mr. Moule, has been fairly tried in this country it has been quite a success; on this point there is abundant testimony from Wimbledon, Broadmoor, Lancaster Prison, and other places.

To us, however, it has always seemed a matter of difficulty to apply the dry earth plan in large towns, on account of the amount of labour entailed in the carriage to and fro of the earth.

This point of the practicability of the dry method is noticed by Dr. Simpson at page 11. It is their stated, on the authority of Dr. Hawkesley, that taking a town of 3,000,000 persons dwelling in 500,000 houses, and dividing these into 500 sections of 1,000 houses each, and each of these sections again into ten sub-sections, that a man and boy, with waggon and horses, would suffice for the requirements of each sub-section. On this plan it seems by rough calculation, that in the case of Manchester and Salford, 850 waggons would be required for the work of removing the excreta of 500,000 persons.

Whether this amount of labour would actually suffice, practice alone can determine; but when the nature of the business is regarded, and the time it must of necessity occupy, we still remain in the conviction that it will never be found to supersede the liquid sewage plan in the large towns of this country.

The fact that the liquid sewage can be turned to most profitable account in agriculture is well shown by the experiments on the farms at Barking and Aldershot.

In villages the dry earth plan is well worthy of trial; it would supply first-rate manure for the farmers, and prevent that pollution of the wells which is so constantly causing outbreaks of fever in country villages.

The remarks of Dr. Simpson on sifted ashes as a substitute for dry earth as a disinfectant, are worthy of notice, and he introduces at the end of his pamphlet some remarks by Dr. Rolleston on "Disinfection" which appeared in the *Lancet* of March last.

◆

CONSUMPTION.*

The subject of climate has been perhaps more thoroughly ill-treated than any others, from gentlemen, who having attained their degrees, have taken a six weeks' scamper through a few popular resorts have come home, looked wondrous wise and retailed the ridiculous stories imposed upon them. Another set of books have been written by adventurers who having pitched their tent in some town, have trumpeted it forth as the *El Dorado* for invalids. Of quiet, unobtrusive observation, there cannot be too much, and gentlemen of the stamp of the author, whose book we now direct attention to, cannot better serve the profession and the public than by the publishing of their impressions. We have read Dr. Thorowgood's work with much pleasure. It abounds in common-sense views tersely expressed. He places a certain amount of reliance on climate, but is by no means, inclined to forget that in availing himself of such influences, he only places the patient in a favourable condition. He has added to his book a very useful chapter on the diet and regimen of the phthisical which embodies all that need be explained to the patient under this head. Dr. Thorowgood strongly believes in bracing, as distinguished from sedative, climates for consumptives, and there is no doubt that this opinion will soon be universally adopted. The growing tendency to try cold climates and high latitudes is proof of this. At the same time, there are many other diseases, and also there are certain conditions of phthisis in which a sedative air is absolutely required, and a bracing one cannot be supported. It is a great merit of this book that it is not confined to the few Mediterranean coast towns which can only be the resorts of the few, and the evils of which have been so fully exposed in our columns this year. We find some very sensible observations on the resorts of our own "tight little island," and we are inclined to believe that the tendency to go abroad will soon be diminished. Those who have not tried such bracing places as Malvern and Harrogate, have no idea what their pure bracing air can accomplish in restoring a frame debilitated by disease or overwork. Then again,

---

* What shall we do with our Refuse? A contribution to the discussion of the Sewage Question. By Henry Simpson, M.D., Lond., Physician to the Manchester Royal Infirmary, and Lecturer on Pathology at the Manchester Royal School of Medicine.

* The Climatic Treatment of Consumption. By J. C. Thorowgood, M.D., 3rd edition. London: H. K. Lewis.

Buxton, Scarborough, Cheltenham, Scotland, and our eastern and southern coasts contain a marvellous variety of good resorts for all seasons of the year, which are only undervalued because they are so near. Dr. Thorowgood relates a very interesting case of a patient having been advised to go to continental resorts, but in consequence of the medical men not agreeing about the particular place, he took the law into his own hands, and in spite of warnings of certain death, went for the winter to his own shooting-box in the bleakest part of the Norfolk coast. His disease was at once arrested, and he still lives to prove the fallacy of the idea that the English climate, even its east coast, is necessarily injurious.

Another case nearly as striking, is recorded, and we commend this view to the candid consideration of all. Another point we would name that must have been noticed by those attached to our consumption hospitals. The out-patients who come in all weathers in the worst winters, do not suffer so much as most would imagine. They often do much better than the rich who shut themselves in doors in bad weather. What is the moral? Is it not that roughing it out of doors is the way to arrest the disease even at the risk of setting up local irritation? It is of great importance that cases should be carefully distinguished, but if all were to be subjected to the same routine let them all rough it.

It is a popular mistake to think that consumption is worse in Great Britain than elsewhere. These islands, according to the latest investigations, do not suffer in any disproportion from other countries and much less than some of the climates to which we have known patients sent. Facts of this kind are of the greatest value, Clearly climatology is in its infancy. It has not been studied with the attention it deserves, and even when it is, we should not forget how secondary climate is to many other considerations.

With the advances that are being made in our knowledge of consumption, we may hope that some advance in this department may also take place.

Correspondence.

REPRESSION OF QUACKERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir—Having seen in your valuable periodical for the 3rd of March, a leading article on the Repression of Quackery, and having given a good deal of attention to the subject, I have come to the conclusion at which you have arrived, that it is in the power of the profession to effect that object, but there must be good arrangement and well directed efforts. Nothing can be effected without a society, and I should think that the first step towards its formation would be the assembly of such physicians and surgeons as are favourable to the movement, in London, Bristol, or other convenient locality, and the appointment of a committee and secretary.

The first thing the committee would have to do would be to send a circular to every physician and surgeon in England and Wales, setting forth the benefits to the profession likely to result from the operations of the society and requesting subscriptions; a shilling from every practitioner would amply suffice for the establishment of the society, and the repetition of that subscription once in two or three years, would be sufficient to maintain it afterwards.

Supposing the society to have been formed and the committee to be in good working order, let them commence operations by drawing up a petition to the legislature, praying first, that a court be established for the trial of all causes in which one party charges another, whether connected with the medical profession or otherwise, with having obtained money for the cure of a disease which he has failed to cure, and secondly, that before any person is allowed to take out a patent for any kind of remedy intended for sale, he should be compelled to pay into the treasury a sum of money sufficient to compensate any party who shall have proved in a court of justice, that the patentee has obtained from him, money on pretence of curing the plaintiff of a disease he has failed to cure.

Again, when a neighbourhood is inundated with advertisements declaring that a certain patent medicine has proved a certain and speedy cure for some serious disease, in ten thousand instances, and that numerous testimonials to its efficacy have been sent to the patentee, let two members of the society go to the vendor, purchase some of the medicine, and then request permission to examine some of the testimonials.

Should these prove to have been written by persons residing in distant places, the members should inform the secretaty of their proceedings, and it will then be his duty to write to members residing in those localities, requesting them to visit the parties who have testified to the efficacy of the medicine, and ask them such questions as the occasion may suggest; they should then report the result of their enquiries to the secretary.

That gentleman should also send some of the medicine to a member who has a taste for analytic chemistry, requesting him to analyze it, and report to him the result of his labour.

As empirics are in the habit of enhancing the value of their remedies by asserting that they have been in use many years. Application to the Patent Office might be made, the date when the patent was applied for ascertained, and thus the truth or falsehood of the assertion be decided.

The society should arrange with the medical officers and governors of hospitals to have patients labouring under those dangerous and incurable diseases which quacks boast they can cure with such marvellous facility, treated with their remedies, the patentees being invited to attend and observe the effects of their remedies.

Of course, great discretion would have to be observed, and no patient should be made the subject of experiment against his, or her, will.

Perhaps the most influential agency that the society could set in motion for the accomplishment of its object, would be the appointment of a lecturer who should visit towns and cities, and at each deliver a popular lecture on quackery, quacks, &c., but the materials for the lecture, which are abundant, I will, with your permission, give in another letter.

I am, Sir,
Your obedient servant,
Bristol. C. Griffith.

◆

THE DIALECTICIANS AGAIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I perceive in your last number an article on Prostitution, which calls for some remarks from myself as touching the question of Population. Fully concurring with Dr. Drysdale, in his objections to the introduction of the Continental System of dealing with syphilis amongst our civil population, and in his appeal on behalf of the poor half-starved work-girls, I feel bound to protest against his insinuating the fallacies of Malthus and Mill. I feel for the shade of Whateley, dragged as it is into such unseemly company; but this penalty his memory has to pay for being tainted with the sin of Malthus.

Let Dr. Drysdale tell us how he proves that prostitution is occasioned by large families. I think, as to poverty, I have demonstrated in my recent paper in the Medical Press and Circular that it is the cause rather than the effect of redundant population.

Let Dr. Drysdale tell us how early marriages are to be managed so as to be childless, or nearly so; does he wish to borrow from Marcus Zand; will he not afford that eminent father in the school of philosophy of which he acknowledges himself an humble disciple, a niche in his temple of fame by the side of the *illustrious* Malthus?

Perhaps Dr. Drysdale will also tell us how the facility of divorce will act as a check on the fruitfulness of marriage. One would expect *a priori* that married couples anxious to be divorced would be less likely to have large families than if the opportunity of remarrying were afforded to them both.

I would once more entreat the medical profession to give their attention to this subject, and not allow infantile murder (whether before or after actual parturition) to be gradually insinuated into fashion, and I cannot refrain from the expression of indignation that a member of our profession, in the position of Dr. Drysdale, should become a party to the inculcating of doctrines of such questionable morality.

I remain, Sir,
Yours, &c.,
Ewing Whittle, M.D. Lond., M.R.I.A.,
Lecture on Jurisprudence to the
Liverpool Royal Infirmary School of Medicine.

Liverpool, May 24th, 1869.

Medical Gleanings.

POST-MORTEM APPEARANCES IN CHOREA AND EPILEPSY IN AN IDIOT.

M. Villard narrates (*Gaz Méd de Paris* No. 4) at length the post-mortem appearances of the brain of an idiot subject to epilepsy and chorea, who died at the age of ten years. The cerebal lobes were asymmetrical, and there was a cyst at the base of the brain.

VENESECTION FOR THE ARREST OF UNAVOIDABLE HÆMORRHAGE.

Dr. C. C. F. Gay of Buffalo, N. Y. (*Am. Journ. Med. Sciences*), claims that venesection, as one of the means for the arrest of unavoidable hæmorrhage, will beyond a doubt, at least in a majority of cases, arrest uterine hæmorrhage. He publishes several interesting cases in proof of this treatment.

IODIDE OF SODIUM IN LEAD POISONING.

The iodide of sodium is advised by M. Rabuteau in treating lead poisoning, instead of iodide of potassium. The former is as active an eliminant as the latter, and no ill effects are produced.

SULPHUR IN THE TREATMENT OF CROUP.

The use of the perchloride of iron, and of the bromide of potassium has been much advocated of late in the treatment of croup and diptheritic angina. The flour of sulphur, which had already been pointed out by different writers as an excellent remedy in similar cases, is now spoken of in most laudatory terms by a French writer, Dr. Feyreigne, of Toulouse, in whose hands it produced most wonderful effects. Dr. Feyreigne only recorded one case, but it was a peculiarly bad one. The patient, a little girl of four years, was in a dying condition with intense diptheritic angina, when the administration of the flour of sulphur brought her back to life, the dose employed was five grammes of sublimated sulphur to one glass of water ; a teaspoonful of the mixture to be given every hour.

CINCHONA IN ALGERIA.

We read in the *Cosmos* that the attempts that have recently been made to introduce into Algeria the cultivation of the cinchona tree will probably be attended with success. Analyses of the bark of the cinchona tree thus cultivated have shown that the alkaloids which constitute their medicinal properties are quite as abundant in these specimens as in others coming from the usual sources.

CORPUSCULA TACTUS.

Rouget in a recent number of Brown-Sèquard's *Archives de Physiologie*, describes some new researches into the structure of the minute corpuscles found on the termination of the peripheral nerves. He calls to mind the discovery of the corpuscula tactûs, by Wagner, in 1852 ; of similar cospuscles, by Messner, in 1853, and of others of a like kind found by Kranse in the conjuntiva and in the mucous membrane of the lips, mouth, tongue, penis, and clitoris. In structure all the corpuscles consist of a central nucleus, a sheath, and a nerve fibril. The sheath is always composed of connective tissue ; the nucleus sometimes consists of connective substance in a hyaline or granular form, and sometimes of nerve substance ; and the nerve fibril makes a close spiral coil around the corpuscle.—*Journal of Cutaneous Medicine.*

OIL OF TURPENTINE IN TRAUMATIC ERYSIPELAS.

Professor Lücke of Bern (*Berliner Klin Wochenschrift*), believes that the local application of oil of turpentine in traumatic erysipelas is very beneficial. The redness disappears in two or three days, and the temperature falls in a remarkable manner under this treatment. By rubbing in the turpentine, rather than pencilling with it, the effect is more rapidly produced. No local irritation results from the application of the turpentine, the patient only complaining of a temporary feeling of burning.

LARGE DOSES OF INDIAN HEMP VALUABLE IN TETANUS.

S. G. Chuckerbutty relates (*Indian Annals of Medical Science*) the results of this treatment in thirteen cases. Death occurred from tetanus from six of the cases ; the others soon recovered from tetanus, though of these three died ultimately from other diseases. Hemp was given in thirty to forty minim doses of the tincture every two or three hours.

SYRUP OF CODEIA IN WHOOPING-COUGH.

A writer in the *Journal für Kinderkranheiten* mentions that melon syrup, containing codeia, is regarded in Italy as a specific against whooping-cough. It is used in other convulsive coughs in children, especially those which are the sequelæ of acute inflammations ; also in the nervous, hacking cough of pregnancy in nervous and sensitive women.

PARASITE IN VACINE LYMPH.

In the fluid of true vaccine lymph, Dr. Haller, of Jena, found large quantities of red or reddish-brown microccocus and mycothrix chains. The particles of the former are so small that even with a magnifying power of 1000 linear they still appear as mere points. When cultivated on the various soils a variety of fungiform growth appear, which, however, all belonged to one species, and formed the following series :—1. Acrospores, corresponding to the Aspirgillus glaucus of Link. 2. Thecaspores the Mucour mucedo of Fresinus. 3. Anaërophytic spores—that is, the Ustilago carbo of Tulasne. 4. Frutification which is the Eurotium herbariorum of Corda. 5. Pycuides, with the subordinate forms, Torula rufescens, Botrytis Jonessi, and Cladosporium.

The micrococcus appears to proceed from the Torula rufescens or Oidium lactis. This torula and its highest state of development, the botrytis, prefer dark places. The eruotium also thrives best in darkness, which is interesting in connection with observations made to the effect that variola heals up without a cicatrix in the dark, and with the observation of Herr. v. Bulmerincq, that direct sunlight soon renders vaccine lymph inoperative.—*Med. Record.*

PROPOSED MONUMENT TO HARVEY.

The *Folkestone Chronicle* publishes the following remarks :—

"That a prophet hath no honour in his own country" is an axiom that has probably never been more fully exemplified than in the instance under review. Dr. William Harvey, the discoverer of the circulation of the blood, was a native of this town, having been born in April, 1578. Dr. Edward Jenner, who made the important discovery of vaccination, was born at Berkely, in Gloucestershire, in the year 1749. Of these two men, probably two of the greatest benefactors of mankind who have ever lived, how different have been the marks of appreciation received at the hands of their fellow men, of the valuable services rendered by each of them to posterity. Public recognition of the invaluable discovery of vaccination, by which thousands, nay millions, have been preserved from the miseries caused by that more distressing malady, small-pox, to which "all flesh is heir," has not been wanting either in England or on the Continent ; for in addition to the large British Parliamentary grants of the sums of £10,000 and £20,000 voted to him at different times during the lifetime of Dr. Jenner, a National Institution called the Royal Jennerian Institution for the promotion of Vaccination was also founded in London in the year 1803, and a statue, subscribed for by all nations, has, in the present half century, been erected to his memory in Trafalgar square, London. Not many years since another statue was also subscribed for, and unveiled by our neighbours on the other side of the water ; and during the lifetime of the First Napoleon, too, so deeply was he impressed with the importance of the services rendered to mankind by Dr. Jenner, that at his request he liberated Dr. Wickham when a prisoner of war, and subsequently whole families of English, making it a point to refuse him nothing that he asked.

On the contrary, has anything like this ever been done for Dr. William Harvey ? or must it be said of him—as great, if not a greater benefactor to the science of medicine than Dr. Jenner—that because he first saw the light nearly two centuries earlier than his confrère, the public have been so slow to recognise the value of his many years of labour and thought, aye even the sacrifice of his own precious life, in the interests and welfare of his fellow man, that neither at home or on the Continent, or even here, the place of his birth, has a memorial of any description ever been raised to his departed worth ; will the British public and our own townsmen then not learn with considerable chagrin and shame, that it has been left to our countrymen at the Antipodes to be the first to show their sense of the incalculable benefits conferred upon the human race by his invaluable discovery of the Circulation of the Blood; and that in the adornment of the House of Assembly in the City of Sydney, a niche was found for a statue of Dr Harvey, among twenty-four of the most celebrated of England's worthies. Let his natural descendants, his townsmen, and the profession generally of which he was so distinguished a member, lay this to heart, and hasten to redeem the time that is past. An opportunity not to be overlooked now offers of doing something in the shape of a memorial in this his native town, as an instalment at least of the justice due to his memory. What more fitting place for such memento than the fine old Parish Church, now undergoing thorough restoration; the Church in which he was baptized; the church in which his early infant prayers were lisped, by the side of that revered mother, whose ashes lie peacefully beneath its sacred aisles. The window of a small chapel in the north chancel, long blocked up, is about to be re-opened; what more fitting receptacle then than this, filled with handsome stained glass, so that when the light of Heaven shall again stream through, its varied tints may portray some appropriate scene in the life of the Great Physician; with a suitable inscription added, recording the great benefits conferred on the whole human family by Dr. William Harvey; that of him may be written a reversal of Shakespeare's truism, that "the evil that men do lives after them; the good is often interred with their bones."

Medical News.

UNIVERSITY OF ST. ANDREWS.

THE following gentlemen having passed their examination, obtained the degree of Doctor of Medicine on the 23rd April last.

Blakeley, Thomas, Bermondsey, Surrey.
Clarke, I. Lockhart, Belgrave, London.
Craster, Thomas, W., Middlesborough-on-Tees.
Fauchie, Martin, Penicuik, Edinburgh.
Jones, Edwin, Blackfriars road, London.
Llewellyn, Llewellyn, Whitechapel road, London.
McMillan, Thomas W., Victoria, Australia.
Neate, Charles, Herefordshire.
Swete, E. Horatio W., Weston-super-Mare.
Welby, Erasmus, Newark:on-Trent.

BIRTH OF UNITED TWINS IN LONDON.—Last week, Mr. J. F. Rogers delivered the wife of a respectable mechanic, residing in the parish of St. Luke's, of twins, which were united exactly in the same manner as the Siamese Twins. The woman, whose age was twenty-three, had been married about twelve months. She is reported to have always been a person of very nervous and excitable temperament. The twins which were still-born, appeared to be fully developed, one being sixteen, and the other sixteen and a half inches in length. Every organ was perfectly formed, the circulation being carried on between the two bodies, by the agency of the umbilical cord. Mr. Rogers has had these interesting specimens photographed, the bodies being preserved in spirits for presentation to one of our Medical Museums.

HEALTH OF ST. PANCRAS.—Dr. Stevenson, the new Medical Officer of Health, has presented his first report on the sanitary state of the parish. He points out the necessity which exists for the erection of a disinfecting establishment, where parishioners might have clothing, bedding, and other articles likely to harbour infected matters, disinfected, was urged upon the vestry by the late Dr. Hillier, Medical Officer of Health, and I can cordially re-echo all that he has said upon the subject. Year by year, in St. Pancras and throughout this metropolis, "preventive diseases" do their deadly work, and it is only the fact that they are constantly among us, cutting down the finest of our people, and do not slay their victims by thousands intermittently, that makes us so indifferent to their pressure. "Of typhus enteric (typhoid) fevers, scarlatina, and small-pox alone, 371 persons died in St. Pancras in 1868. I have no hesitation in saying that the mortality from these diseases might have been very largely diminished had there been proper provision, such as the Vestry is empowered to provide by the Sanitary Act, 1866, for the disinfection of clothing, &c. The cost of such an establishment as one of those erected in Liverpool would, I doubt not, be soon saved to the parish by the saving of life that would be effected. Fevers (especially typhus) attack more especially our adult population and of the 122 persons who died from fever in St. Pancras last year a large proportion were adult males who had families dependent upon them. If we could add to these deaths the number of those persons who were disabled and unable to work during the attacks of fever it would be seen what distress and misery must be caused, resulting, of necessity, in a largely increased poor-rate. I cannot too earnestly recommend to the authorities the consideration of this question in its economic aspect."

NOTICES TO CORRESPONDENTS.

MR. WHATFORD requests us to correct a printer's error in his letter. Agony for Agency. Also, excellently for excellent, and one or two others. Mr. Whatford says also he is not M.R.C.S.

DR. EVANSON, France.—Your address shall be altered as desired.

MR. FRENCH.—Mr. Walton, of Gower street, London, is the publisher of the book in question. You might possibly get it second-hand of Mr. Lewis or Mr. Kimpton.

OUR COCOA REPORTS.—There are several engravings to be executed, showing the starches and other ingredients used for the purposes of adulteration. We are compelled to curtail this week's report, in consequence of some of the blocks not being free of the engraver.

MR. W. J. C., Chipping.—Many thanks.

ON THREE CASES OF ANEURISM OF THE AORTA. By J. Lamprey, M.B. Proof of your paper shall be sent you at once. We regret the delay, which has been caused by the extraordinary number of communications sent us for publication by our numerous friends, during the past four months. We are now getting free of the number, so that we can promise contributors space, with as little delay as possible. Short practical communications in every case receive the preference.

DR. CROTHERS, Nice.—The alteration shall be attended to.

DR. KELLY, Macroom.—Your letter on Vaccination shall appear in our next.

COMMUNICATIONS, Enclosures, &c., received from Mr. Jonathan Hutchinson: Mr. F. B. Courtenay, London; Mr. P. Le Neve Foster; Messrs. Nelson and Sons, Leeds; Mr. Eschwege; Mr. I. Barras, Rotherham; Mr. Crafter; Mr. Hulke; Dr. Farre; Dr. Handfield Jones; Sir William Ferguson, Bart.: Dr. Little; Dr. Lionel Beale; Dr. Tilt; Mr. Skey; Dr. P. Hood, London; Mr. C. Griffith, Bristol: Mr. Merriman; Dr. R. Wallace, Chillington; Dr. Atkins, Sidmouth; Professor Humphry, Cambridge; Mr. Tichborne, Dublin; Dr. Paine, Philadelphia; the Secretary of the British Association for the Advancement of Science; Dr. R. Tonson Evanson, Paris; Mr. Teevan, London; Dr. Mapother, Dublin; Dr. E. D. Gribbin, Belfast; Dr. A. N. Kidd, Armagh; Dr. Robert Walker, Glasgow; Dr. Hardman, Bristol; Weeden Cooke, Esq., London; Mr. W. J. Cox, Hawkesbury; Dr. Gordon, C.B., Portsmouth; Dr. Beveridge, Aberdeen; Dr. Chalmers: Dr. Johnson; Dr. Ewing Whittle, Liverpool: Dr. Rogers, London, &c.

MR. R. SUMMERS, Haverfordwest.—The case appears at first sight to be a very flagrant one, deserving the contempt of every right-thinking man. We are unable to publish your letter in our present numbet, but hope to find space for it in our next. Should any local paper contain a report of the trial, please forward same to us at once.

CASE OF UNITED TWINS.—Dr. J. F. Rogers, St. Luke's, will please accept our best thanks for the photograph of the above, and for his polite note.

APPOINTMENTS.

JOHNSON, Edward, S., Dr., of Cavendish Place, London, Honorary Medical Referee to the Seaford Convalescent Hospital.

FASKON, Wm., Dr. has been promoted Chief Surgeon, and Mr. S. B. Johnson, Assistant-Surgeon to H.M.S. Monarch.

VACANCIES.

Castlebar Union.—Medical Officer. Election on Saturday. See advertisement.
Dental Hospital of London.—Dental Surgeon Honorary.
York County Hospital.—Non Resident Dispenser. Salary £65.
Royal College of Physicians, London.—Under Secretary and Bedell. See advertisement.
Worcester General Infirmary.—Assistant House-Surgeon. Salary £50 with board, &c.
Middlesborough Infirmary.—House-Surgeon. Salary £70, with board and residence.
Middlesex Hospital.—Physician's Assistant, to be held for twelve months. Board and residence provided.
St. Pancras, Middlesex.—Medical Officer. Salary £175, with board and residence.
Lancaster Infirmary.—House-Surgeon. Salary £90, with appointments.

BOOKS RECEIVED.

The Middlesex Hospital Reports for the year 1868.

A Manual of Orthopraxy. By Henry Heather Bigg, C.E., 2nd edition, enlarged. London: John Churchill and Sons.

A Theory on Counter Irritation. By James Ross, M.D. London: John Churchill and Sons.

Transactions of the St. Andrew's Medical Graduate's Association for 1868. Edited by Dr. Leonard Sedgwick. London: John Churchill and Sons.

Squire's Companion to the Pharmacopœia. Seventh edition, revised and enlarged. By Peter Squire, F.L.S. London: John Churchill and Sons.

Births.

GRIBBIN.—On May 18th, at Great Edward street, Belfast, the wife of E. D. Gribbin, L.F.P.S., and L.S.A., of a son.

KIDD.—On the 20th inst., the wife of Archibald Napier Kidd, M.D., F.R.C.S.I., Armagh, of a daughter.

Advertisements.

WANTED as BEDELL to the ROYAL COLLEGE of PHYSICIANS, and as SECRETARY under the REGISTRAR, a married man without children, whose wife will be the HOUSEKEEPER of the COLLEGE.

Applications, with statement of qualifications, to be sent to the Registrar at the College, Pall mall East, where full particulars may be obtained. The duties of the Bedell will commence on the 24th of June, 1869.

THE LONDON SURGICAL HOME,

FOR DISEASES AND ACCIDENTS OF WOMEN; for the Reception of Gentlewomen and Females of respectability, upon a weekly payment, under the sole management of Mr. Baker Brown.

The Private Medical Attendants of the patients are invited to visit them, and to meet in consultation before treatment.

Full particulars can be obtained on application to the Lady Superintendent, 136 Harley street, near Regent's Park, London.

PRIVATE RETREAT
FOR
THE UPPER AND MIDDLE CLASSE
OF BOTH SEXES,
MENTALLY AFFLICTED,
TUE BROOK VILLA,
NEAR LIVERPOOL.

Further information may be obtained on application to Dr. H. OWEN.
Vide page 1075, "Medical Directory," 1869.

ALBERT LIFE ASSURANCE COMPANY,
7 WATERLOO PLACE, PALL MALL, S.W
LIVES ASSURED,
DISEASED AS WELL AS HEALTHY.

ABSOLUTE SECURITY POLICIES, UNFORFEITABLE, UNCONDITIONAL, and UNCHALLENGEABLE issued by the **PRUDENTIAL ASSURANCE COMPANY** (Established 1848), No 62 Ludgate hill, London, E.C.; Branch Office, 7 King street, St. James's.

The Directors of this Company, in deference to an objection not unfrequently urged by persons invited to assure, that the ordinary mode of life assurance is in their opinion defective or uncertain, by reason of the operation of the customary conditions, have resolved to promulgate the present tables, and to issue assurances under them which shall be absolutely unforfeitable, unconditional, and unchallengeable.

For the reason referred to, many persons hesitate or decline to assure on the ground that, in the event of inability or unwillingness to continue payment of their premiums, the assurance will become forfeited. To this class of the public the system now introduced will especially commend itself, being entirely free from all conditions of forfeiture on account of non-payment of premium, or from any other cause whatever; while at the same time it absolutely guarantees at decease, even when a default is made in payment of the premium, a fixed sum in respect of every premium paid, bearing the same proportion to the total amount assured as the number of premiums actually paid may bear to the whole number originally contracted to be paid. Besides this important advantage, every policy will expressly state what sum can at any time be withdrawn on the discontinuance of the assurance. The assured will thus always have the option of retaining either an ascertained fixed sum payable at decease, or, in case of need, of withdrawing a certain amount, according to the duration of the policy, such amounts being set forth on every policy, and rendering unnecessary any future reference to the Company on these points, as is the case with ordinary assurances. Creditors assuring the lives of debtors will appreciate this feature as one greatly protective of their interests, and it will likewise commend itself to bankers, capitalists, and others who are in the habit of making advances collaterally secured by life policies, as they can at any time learn, by mere inspection, the exact value, either immediate or reversionary, of a policy of this description. Every policy issued on this plan will be without any conditions as to voyaging, foreign residence, or other usual limitations. By this freedom from restrictions of all kinds, the objections before referred to will be entirely removed, and the policies will become at once positively valuable as actual securities.

In addition to the foregoing statement of advantages the number of premiums is strictly defined. The longest term provided for is twenty-five years, and the shortest five years, as shown by the tables. Thus, bankers, creditors, and others holding policies of this class as security, may always know the utmost amount they may be called upon to advance, so as to maintain the full benefit of the assurances—a matter of great importance where policies are held as collateral security.

It is only necessary to add that, as a consequence of the policies under these tables being unforfeitable and unconditional, they will also be unchallengeable on any ground whatever. They may, therefore, be aptly termed Absolute Security Policies.

The Prudential Assurance Company possesses an income of £200,000 a-year. Its position is unquestionable, and it obtains the largest amount of new business of any office in the kingdom.

Special agents wanted. **HENRY HARBEN, Secretary.**

IRISH MEDICAL ASSOCIATION.
ROYAL COLLEGE OF SURGEONS IN IRELAND.

NOTICE is hereby given, that the ANNUAL MEETING and DINNER of the IRISH MEDICAL ASSOCIATION will take place on MONDAY, the 7th of JUNE next.

The Meeting will be held at the Royal College of Surgeons, Dr. Rawdon Macnamara, President of the Association, will take the Chair at Twelve o'clock.

The Dinner will take place at the Exibition Building, at Seven o'clock.

By Order, E. J. QUINAN, M.D. Hon. Sec.
15th May, 1867.

CARMICHAEL SCHOOL OF MEDICINE,
NORTH BRUNSWICK STREET.

THE SUMMER SESSION COMMENCED on MONDAY, APRIL 26, 1869.

Practical Chemistry	Dr. E. Davy	Tues., Thurs., Sat., 12 to 1 o'c.
Materia Medica	Dr. Fraser	Mon., Wed., Fri., 12 to 1 „
Medical Jurisprudence	Dr. O'Reilly	Mon., Wed., Fri., 1 to 2 „
Botany	Dr. Campbell	Tues., Thurs., Sat., 1 to 2 „

Carmichael Medals and Prizes will be awarded in each of the Summer Classes. For particulars apply to

Dr. CORLEY, Registrar, 14 Summer hill.

CASTLEBAR UNION.

CASTLEBAR DISPENSARY DISTRICT.

NORTH DIVISION, COMPRISING THE ELECTORAL DIVISIONS OF TURLOUGH, PONTOON, ADDERGOOLE, BALLYNAGORAHER, CROAGHMOYLE, AND BURREN.

MEDICAL OFFICER WANTED for the above Division. Notice is hereby given, that the Committee of Management of the above Dispensary District will, at their Meeting, to be held at the Board Room of the Workhouse on SATURDAY, the 29th day of MAY, 1869, at the hour of One o'clock, proceed to the appointment of a PROPERLY QUALIFIED MEDICAL OFFICER for the above Division (in which he will be required to reside), at a Salary of Ninety Pounds a-year, exclusive of Registration and Vaccination Fees.

Candidates must possess the qualifications set forth in the orders of the Poor-law Commissioners.

Applications, with testimonials, to be addressed to the Secretary, John C. Larminie, Esq., Spencer Park, Castlebar, up to the hour of One o'clock, on the 15th day of May, 1869, at which hour Candidates must be in attendance.

By Order,
ROBERT J. NIXON, Clerk of Union.

Board Room, Workhouse,
Castlebar, 15th May, 1869.

RATHDOWN UNION.
BLACKROCK AND STILLORGAN DISPENSARY DISTRICT.

MIDWIFE WANTED.

THE COMMITTEE OF MANAGEMENT of the BLACKROCK and STILLORGAN DISPENSARY DISTRICT, will, at their meeting to be held at the Dispensary, Blackrock, on Wednesday, the 1st June, 1869, proceed to consider the Testimonials of properly qualified Candidates, at a salary of twenty pounds per annum.

Candidates to forward their Applications with Testimonials (post free) to William John Walnutt, Esq., Honorary Secretary, Blackrock on or before ten o'clock A.M., on the 1st prox., when it will be necessary for Candidates to attend in person.

The person appointed will be required to reside in Blackrock.

By Order. J. D. COPE, Clerk of the Union.
Board-room, Loughlinstown, 5th May, 1869.

KREOSOTE.

CAUTION TO BUYERS.—The Sole English Manufacturers of this article are the undersigned:—

THOMAS MORSON & SON,
31, 33, and 124, Southampton-row, London, W.C.

TO THE MEDICAL PROFESSION.

LOEWENTHALS'
NEWLY INVENTED AND REGISTERED
CHOCOLATINE
IS ACKNOWLEDGED BY THE BEST AUTHORITIES AS
THE PUREST EXTRACT OF COCOA
OBTAINABLE,

SURPASSING every other Cocoa or Chocolate in *anti-dyspeptic*, *anti-flatulent*, *tonic* and *nerve-soothing* properties, as most delicious in taste and suitable alike.

"For the ROBUST, the INVALID, and the CHILD" Vide—*British Medical Journal*, April 3rd, 1869; *Medical Mirror*, March 1st, 1869; and other Medical Papers.

Sold by most Chemists and Grocers in packets, 9d., 1s. 6d., 3s., and 5s. 6d. each.

N.B.—A sample *gratis* by enclosing a stamped envelope to the WHOLESALE DEPOT, 70 FENCHURCH STREET, London, E.C.

GLEANINGS IN TOXICOLOGY.

No. IV.

By **Charles Meymott Tidy**, M.B., M.S.,
Joint Lecturer on Chemistry at the London Hospital.

Strychnia is the poisonous alkaloid of several plants. It was discovered as lately as 1818, by Pelletier and Caventou. The poisonous properties of the strychnos nux vomica, from which the alkaloid is usually prepared in this country, was probably known to the Arabians, although Dr. Pareira, seems to think the remarks of Arabian authors had reference rather to the bean of S. Ignatius than to the nux vomica. Probably, moreover, the poisoned arrows of old-fashioned warfare, as well as of modern barbarians, owe their poisonous action to being steeped in a solution of one of the strychnos family. Fatal accidents have occurred by the bark of the strych. nux vomica having been substituted for Angustura bark (hence called false Angustura bark), but from which it may easily be distinguished by its twisted-like appearance, by its being peculiarly spotted, by the absence of smell and its bitter taste (from the strychnia it contains); and lastly, by the impossibility of separating it into layers.

The seeds of the strych. nux vomica are very peculiar. They are called by the Germans "crows' eyes," from some supposed similarity. Some short time back I was consulted respecting the composition and properties of a seed which had a most striking resemblance to the nux vomica; but finding it had no poisonous action on animals, nor that I could discover a trace of either brucia or strychnia in it, I asked a well known botanist, who considered it was in all probability the seed of some foreign cucurbetaceous plant. I mention this because I have never seen any notice taken of the close resemblance between some seeds of this order and of the strychnia family.

Strychnia is invariably found associated with another alkaloid, brucia. It is also always present in the plant in combination with an acid.

Brucia has similar properties, and produces almost similar physiological effects to strychnia, but not in the same degree—that is to say, it is considerably less active. Endeavouring to fix the relationship between them, I find that 1-1000th of a grain of strychnia produced convulsions in a frog in seven minutes (given by mouth); whereas, to produce the same effect in the same time, it was necessary to administer about the 1-100th of a grain of brucia; or, in other words, strychnia is as nearly as possible ten times more powerful in its action than brucia. I do not think either that the convulsions were quite so severe, nor did they last so long in the case of poisoning by brucia.

Respecting *the quantity* that will destroy life. Christison poisoned a dog by injecting one-sixth of a grain into the chest in two minutes, and (2) a wild boar by injecting one-third of a grain in the same way in ten minutes. Dr. Letheby had a case at Jersey, in 1856, where death resulted in five or six hours after a woman had taken half a grain by accident. I have had a case lately where a young woman committed suicide with some "Battle's vermin killer," and from the quantity she bought and the amount I found it contained, I judge she could not have taken more than a quarter of a grain. Death in this case took place in ten hours, the symptoms commencing, as nearly as we can judge, in about half an hour after she had taken it.

Respecting *the symptoms*. I may just quote from the account rendered me, by the medical man, of the above-mentioned case. The girl, when he first saw her, had severe muscular twitchings, her countenance wild and anxious, the face blue, and her skin covered with cold perspiration; the eyes were staring. She was, as a rule, muttering, but now and then called out hastily, "I am choking, I am choking;" at other times, "give me some water, why do you not give me some water." Very shortly afterwards regular tetanic convulsions came on, the pupils were dilated, the pulse was so quick that it could not be counted; it had also a peculiarly indistinct character. The position was what is called "opisthotonos." The spasms lasted about two to three minutes; the interval, if left undisturbed, varying from five to ten minutes; but the spasms were brought on directly upon the slightest touch, as on bringing a glass of water to her lips, for which she was eagerly craving. In one spasm, a very severe one, the pupil was so much dilated that the iris was scarcely visible. The spasms continued to increase until death.

I do not know that I have anything very definite to say about the *post-mortem* appearances. In two cases I find noted that the hands were clenched, excepting the *index fingers*, which were extended. In most cases the heart is empty, and in all I find noted extreme congestion of the brain and spinal cord. The appearance of the stomach is by no means characteristic; I have seen it in two cases that have come under my notice intensely congested, in a third comparatively normal.

We may now examine some of the properties of this drug. It is when pure perfectly white, crystalline, and of an intensely bitter taste. Its solubility being a matter of great importance, I have made some fresh experiments, of which I give a summary, and the shape of the crystals formed on evaporating off the solvent.

1. *Chloroform*, 1 in 10.—Crystals not well formed; sometimes occurring, however, in rosettes or tufts.
2. *Dutch Liquid*, 1 in 30.—Residue reddish and not very crystalline, when only a small quantity is operated with; otherwise, when evaporated in bulk, the crystals are large, long, rectangular prisms.
3. *Alcohol*, 1 in 100.—Crystals brilliant and sparkling; modified rectangular and rhombic prisms; the opposite acute angles often replaced by planes; size of crystals dependent on quantity, but always well formed.
4. *Benzole*, 1 in 250.—Crystals very large; prisms and octahedra.
5. *Ether*, 1 in 340.—Crystals flat prisms, sometimes small and serrated.
6. *Bisulphide of Carbon*, 1 in 1,000.—Residue white and granular; forms indistinct.
7. *Water*, at 60° F., 1 in 7,000; at 212° F., 1 in 2,500 — Crystals small and very indistinct; in large quantities with the naked eye they appear in nodules.

The *acetate* is of all the salts that which is the most soluble in water and alcohol. It is not very soluble in ether. It forms long needle-shaped crystals, arranged in rosettes or plumuse tufts, or as large plates lying side by side.

The *sulphate* is not very soluble in water. It occurs under the microscope as small rectangular plates, or as large elongated needles.

We shall examine in our next paper the chemical and other tests for detecting its presence.

◆

PATHOLOGICAL OBSERVATIONS.

By R. Beveridge, M.D.,

Physician and Pathologist to the Royal Infirmary, Aberdeen.

CASES OF SUDDEN DEATH.

At one time it was the custom to attribute all cases of sudden death to the occurrence of apoplexy; but as more correct views came to be entertained of the pathology of this disease, it became apparent that the mere effusion of blood into the substance of the brain could not give rise to sudden death, although it might prove fatal after the lapse of a few hours. When affections of the heart came to be more thoroughly understood, it was found that in many cases, they were capable in some of their forms, of producing sudden failure of the action of the organ, and so of causing death with the serious symptoms prolonged over a few minutes at most, and so the fashion has become common—perhaps too common—of ascribing to them, all cases of sudden death. That this is also an error, although perhaps not so great a one as the former, will be readily admitted; and it would doubtless lead to much greater precision, and perhaps to the discovery of interesting pathological changes in their early stage, if *post-mortem* examination was insisted on in *all* cases of sudden death. The following cases may be interesting as illustrating how rare lesions, unsuspected during life, may give rise to sudden death.

Sudden death from asphyxia produced by hæmorrhage, proceeding from cancer of the lung.—J.W., a mason, æt. sixty-four, a stout robust man, had always enjoyed good health, with the exception that for a few days previous he had complained of slight cough, with a feeling of weight in the chest, but not to such an extent as to hinder him from working. On the evening of the 26th August, 1867, he was proceeding leisurely home with his son, when he suddenly complained of feeling faint, tried to walk on but could not, sank down in the street, spat up a little blood and died in a few minutes.

Post-mortem examination twenty hours after death.—Body stout and well nourished. Larynx, trachea, and bronchi of both sides contained a considerable quantity of blood, not frothy, chiefly fluid but partly coagulated. This extended into the minute tubes of both sides. Bronchial mucous membrane healthy. Lungs voluminous; left healthy; right healthy in its two upper lobes; lower lobe feeling in its centre, firm, hard and solid, and having its surface marked by a depression. In the centre of this lobe, near its inner surface were two small cancerous masses about the size of small filberts, firm, hard, white, and cutting crisp under the knife, very abruptly marked off from the surrounding tissue; close to one of these masses passed a bronchus of some size which was ulcerated to a considerable extent, and through the gap thus formed projected one side of the mass into the interior of the tube. This appeared to be the source of the blood. Heart empty, cavities firmly contracted, walls and valves healthy. Great vessels of the neck, chest and abdomen healthy. Rest of the viscera healthy, with the exception of the kidneys, both of which were to some extent granular, and the right presented also two cysts, one of some size in the upper parts of the organ.

Cancer of the lungs is at all times a rare occurrence, and primary cancer especially so, which renders this case all the more singular, as none of the other organs of the body showed any trace of cancerous deposit. The mode of death too was very unusual; that it was caused by rapid effusion of blood filling the bronchi of both lungs is unquestionable from the appearances, and that this effusion resulted from the ulceration of a bronchus, caused by pressure of the hard cancerous mass upon it seems also clear, as no other source for the blood could be detected on careful examination, and the appearances immediately around that spot, showed that it and it only was congested or altered from the natural appearance; the rest of the right and the whole of the left lung was healthy. The quantity of blood actually lost was trifling, but it had flowed so quickly as to fill rapidly the smaller bronchi of both sides, and so produce speedy death. It may be said that the empty condition of all the cavities of the heart, is inconsistent with such a mode of death; but that such a state of the heart may occur in death from asphyxia the following case of hæmoptysis will show. A young man, in the early stage of phthisis, was attacked with a fit of hæmoptysis, which, after lasting a short time in the usual way, suddenly proved fatal. On *post-mortem* examination both lungs were found to contain tubercle, which was more abundant in the right than in the left, and was firm and hard everywhere, except in the apex of the right lung where softening had begun, and where there existed two small cavities. These, together with the trachea and both bronchi, contained dark coloured blood, and the glottis was blocked up for nearly half its extent by a clot. The heart was nearly empty, containing a very little fluid blood, in about equal quantity on both sides. In this case hæmoptysis, proceeding from its most usual cause phthisis, produced sudden death with nearly the same appearances as occurred in the case of cancer, with this as the main difference, that while in the one case the existence of disease of the lung was known and extensive, in the other it was unsuspected and very limited.

Sudden death from tumour in the walls of the heart.—J. M., a healthy child, was suddenly seized with what was called a fit, which, from the somewhat confused description given by the nurse, seemed to be of the nature of a faint, and almost immediately expired. On *post-mortem* examination, all the organs of the body were found to be healthy, with the exception of the heart, which presented, in the anterior wall of the left ventricle near its base, a firm tumour about the size of a walnut, scarcely noticeable externally, but projecting considerably into the cavity. The mass which was partly imbedded in, and seemed partly to replace the muscular tissue of, the ventricular wall, was formed of fibres arranged in a concentric manner, and presented both to the naked eye, and to the microscope, the appearance of an ordinary fibrous tumour. Such a case as this is more of a pathological curiosity than of practical interest. Rokitansky states "We have never observed fibroid tissue in the heart, under the form of an independent fibrous tumour."[*] That such a mass should have gradually formed without producing some derangement of the circulation is very unlikely, but this had never gone to the extent of attracting attention, and so as in many cases, no suspicion was entertained that dangerous mischief had arisen, until the occurrence of syncope, arising very probably from some trivial cause, but from which the heart, in its enfeebled condition, failed to rally, and thus a sudden fatal result ensued.

◆

Our Analytical Department.

COCOA.

REPORT ON THE QUALITY AT PRESENT SUPPLIED TO THE BRITISH MARKET.

(Continued from page 436.)

Thus, cocoa may be divided in the following manner, after removing the woody fibre, which is worthless as a nutritious element:—

Theobromine	2	22 Flesh formers.
Albuminoid	20	
Butter	50	63 Heat givers.
Gum	6	
Starch	7	
Mineral matter	4	
	89	Playfair.

In the analyses given in this report it has not been considered desirable to go to small fractions in recording the results.

Figs. 1, 2, and 3 represent the starches most frequently used in adulterating cocoas.

1st Sample.—Raw Cocoa Bean.

(Not an article of commerce.)

Obtained from Messrs. J. and S. Fry and Sons, London and Bristol.

Moisture, 5·6 per cent.; ash (white), 4 per cent.; cocoa butter, 46·6 per cent.; starch, 12 per cent.—*Genuine.*

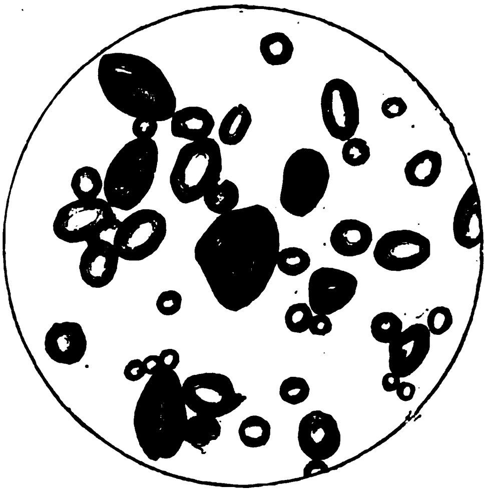

Fig. 1.—Potato starch magnified, 200 diameters. This and the following plates are engraved from micro-photographs especially taken by Mr. Woodworth to illustrate these reports.

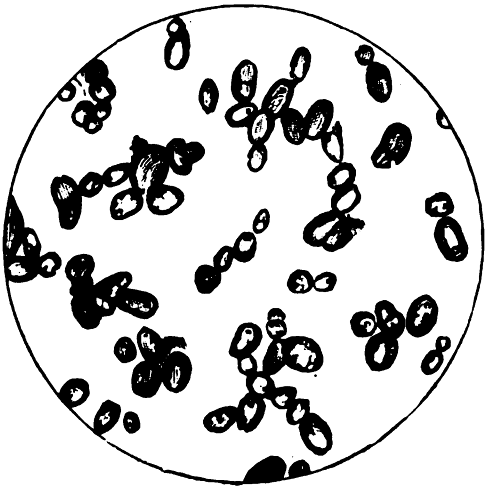

Fig. 2.—Bermuda arrowroot, 200 diam.

2nd Sample.—"Finest Roasted Cocoa Nibs."

From Messrs. J. and S. Fry and Sons, London and Bristol.

Moisture, 3 per cent.; ash (white), 3 per cent.; cocoa butter, 49 per cent.; starch, 11 per cent.—*Genuine.*

3rd Sample.—"Pure Chocolate Cake."

Messrs. J. and S. Fry and Sons, London and Bristol.

Similar to third sample.—*Genuine.*

4th Sample.—"Cadbury's Cocoa Essence."

Messrs. Cadbury, Brothers, Birmingham.

From Messrs. Cadbury's advertisement.—"The main features in the preparation of the 'cocoa essence' are, that about two-thirds of the fatty matter is removed, and the stimulating and flesh-forming constituents developed and rendered sufficiently soluble for the whole to be taken; whereas, in using the nib, an important part of these is thrown away. It also has the advantage of being quickly prepared.

---

[*] Syd. Soc. Trans. Vol. iv. p. 209.

"This essence is about three times the strength of the best Homœopathic cocoas and the French chocolates ordinarily sold, where the fatty matter has to be counteracted by the addition of arrowroot, sugar, &c., and being perfectly genuine does not thicken in the cup, when prepared for use, like adulterated cocoas.

"One hundred parts of tea, coffee, and cocoa are thus analytically divided by Dr. Lyon Playfair:—

	Tea.	Coffee.	Cocoa Nibs.	65 parts of Cadbury's 'cocoa essence' contain—
Water	5·000	12·000	5·000	4·000
Thein, caffeine, or theobromine..	3·000	1·750	2·000	2·000
Albumen	———	———	20·000	20·000
Casein	15·000	13·000	———	———
Aromatic oil	0·750	0·002	———	———
Gum	18·000	9·000	6·000	6·000
Starch	———	———	7·000	7·000
Sugar	3·000	6·500	———	———
Fat	4·000	12·000	50·000	16·000
Tannic acid	26·250	———	———	———
Potash, with acid	———	4·000	———	———
Fibre	20·000	35·048	4·000	4·000
Mineral Matter	5·000	6·700	4·000	4·000
Red colouring matter	———	———	2·000	2·000

This packet of cocoa contained three ounces of the cocoa, wrapped first in paper and then in tin foil; examined microscopically, it was found to contain nothing but cocoa. The ash, which was white, was 6 per cent.; cocoa butter, 26 per cent. A considerable quantity of the butter is evidently removed from this cocoa. We believe the plan adopted by the French and English is to place the liquid chocolate in a bag of moderately close material; this is then dropped into a box with holes at the bottom, and a lid, which fits closely *into* the box, is screwed down tightly upon it, and so forces the butter out through the bag.—*Genuine: very good cocoa.*

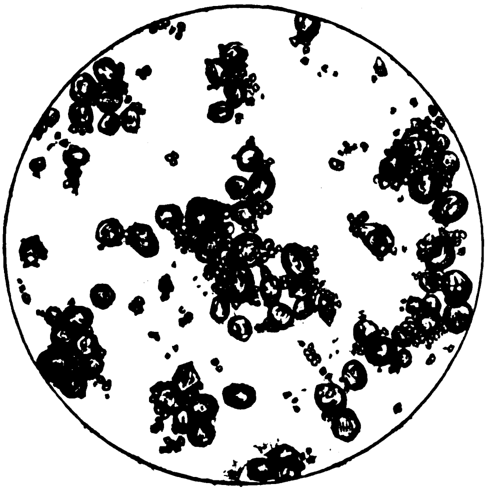

Fig. 3.—Wheat starch, 200 diam.

5th *Sample.*—"Cadbury's Cocoa Essence."

A sample sent to the members of the medical profession through the post.

Similar to the fourth sample.—*Genuine; very good cocoa.*

6th *Sample.*—"Epps' Prepared Cocoa."

Messrs. James Epps and Co., London.

In four ounce packets, retailed at 5d., wrapped in tin foil. The tin foil contained a trace of lead, but was nearly pure; consists of about 33½ parts of sugar, 10½ parts of starch (arrowroot), and 56 parts cocoa. It gave 1·25 of an ash slightly coloured, and 28 per cent. of cocoa butter.—*Not genuine; contains starch and sugar.*

7th *Sample.*—"Cadbury's Chocolate du Mexique."

Messrs. Cadbury, Brothers, London.

Nearly pure cocoa, with about its own bulk of sugar. Contains a few starch granules; ash 3 per cent., nearly white.—*May be considered as a fair specimen of chocolate.*

8th *Sample.*—"Van Houten's Pure Soluble Cocoa."

Manufactured by C. J. Van Houten & Zoon, Weesp, Holland.

Consignee, H. Eschwege, London.

From advertisement.—"Guaranteed to contain pure soluble cocoa, of the finest quality and full weight. . . . Unequalled by any other cocoa preparation for its purity, flavour, strength, and comparative freedom from fatty matter."

Opinion of Dr. Hassall.—"I have tested chemically, microscopically, and dietetically Van Houten's cocoa, and contrasted it with the best descriptions of cocoa and chocolate to be found in the English market. While the great majority of them consists of mixtures of cocoa, starch, &c., Van Houten's is not only composed solely of the cocoa bean, but is of the finest quality. Although nominally dearer than many of the English preparations, from its greater purity and strength it goes much further, so that in the end it is really much cheaper. From its greater purity, also from the smaller proportion of fatty matter present, together with its superiority of quality and comparative cheapness, it is well suited for use in hospitals and other public institutions."

The ash was 9 per cent. in this cocoa, and nearly white; it seemed to contain a little colouring, but is evidently, in other respects, a pure cocoa, with some of the butter removed. The percentage of fat was 30 per cent. We cannot endorse Dr. Hassall's remarks, however, as regards the comparative cheapness of this cocoa.—*Genuine, and very good quality.*

9th *Sample.*—Cacao en Poudre.

Fabrique de Chocolat Menier.

This cocoa was in a tin canister, which contained 4 oz. 248 grains; this quantity only half filled the canister. It gave nearly 5 per cent. of a white ash, and contained about 48·5 per cent. of cocoa butter. Examined microscopically, it was found to be perfectly pure, except that it contained a very small proportion of the husk.—*Genuine; fair quality.*

10th *Sample.*—"Iceland Moss Cocoa."

Messrs. Dunn and Hewett, London.

From Advertisements.

"The two articles here combined are well known for their nutritive qualities. The moss contains a large portion of nitrogen—or flesh-producing substance,—and being prepared by a very careful and peculiar process, which frees it from all the grittiness and disagreeable flavour which is always so unpleasant, is rendered perfectly pure, with nothing but the beneficial parts left."

"The cocoa, containing more nutriment than most articles of food, being combined with the moss, forms in this mixture an article of the greatest importance to the invalid, and at the same time beneficial to the healthy and robust, restoring health where it is declining, and retaining it where already enjoyed."

Report by A. H. Hassall, Esq., M.D.

"I have carefully examined, both microscopically and chemically, the preparation of Iceland moss and cocoa made by Messrs. Dunn and Hewett; I find it to be carefully manufactured with ingredients of the first quality.

"The combination of Iceland moss and cocoa forms a valuable article of diet, suited equally for the robust and for invalids, especially those whose digestion is impaired. It is very nutritious, of easy digestibility, and it possesses moreover tonic properties.

(Signed) "ARTHUR H. HASSALL, M.D."

This preparation gave 2 per cent. of greyish ash, and consisted of about 48 per cent. of cocoa, 32 of sugar, and about 20 per cent. of Iceland moss and arrowroot, the latter in excess. This is, therefore, *a mixture of Iceland moss, cocoa, sugar, and arrowroot.*

11*th Sample.*—"FRY'S CHOCOLATE CREAMS."

Messrs. J. and S. Fry and Sons, London and Bristol.

These chocolate creams were small tablets of pure chocolate, containing sugar in the centre, each tablet wrapped round with tin foil; they gave ·6 of a grain of ash, which was very white; the sugar amounted to nearly 50 per cent. This and the two next samples were beautifully made. Whilst on this subject we may offer a suggestion to some of the manufacturers—viz., not to use tin foil in immediate contact with the articles, particularly such as the above. The main object of using tin foil with cocoa is to keep in the aroma, &c.—an object of no small importance when we consider the long time that many of these packets are sometimes stored on the retailers' shelves; but the object is equally gained by wrapping first in paper and then in tin foil. It is a well known fact that the tin foil of commerce nearly always contains lead, and sometimes a large proportion. Now, if we take any moderately oxidizable metal, such as lead, silver, &c., and rub its surface with a little cotton wool and oil, we shall find that the wool is covered with a black substance, simply because the metal is covered with an extremely minute film of oxide, which is mechanically rubbed off by the wool. Platinum and gold, or unoxidizable metals, do not give this result. Now, if the tin foil contains lead, that metal will ultimately contaminate the substances with which it is in contact, particularly if the packet gets damp or if it is in *actual contact with grease.* Thus, the foil round Messrs. Fry's chocolate creams consisted of—

Tin	90
Lead	10 (9·8)
	100[*]

We do not draw attention to this matter for the sake of making any sensational paragraph, as we are well aware that the quantity of lead present was too minute in the above samples to do any serious harm; but where this contamination can be so easily avoided there is no object in running even a slight risk.

12*th Sample.*—"FRY'S CHOCOLATE CREAMS, NO. 300."

Similar to the above, but not wrapped in tin foil.—*A wholesome confectionery chocolate, with sugar.*

13*th Sample.*—"FRY'S CHOCOLATE BONBONS."

Similar to samples 11 and 12, only containing less sugar and flavoured with cassia.

14*th Sample.*—"CARACCATINA."

Messrs. Dunn and Hewett, London.

From advertisement.—"A pure preparation of the caraccas nut. This cocoa is superior to any other in strength or flavour, and is recommended as the most genuine and nutritious article yet introduced."

This preparation gave a greyish ash amounting to 3 per cent. It consists of pure cocoa, with about 20 per cent. of the cocoa butter removed. A few granules of starch were present, but they were evidently accidentally there.—*Genuine, and very fine flavour.*

15*th Sample.*—"HANDFORD AND DAVIES' PURE GRANULATED COCOA."

Messrs. Handford and Davies, London.

From Advertisement.

"Of all articles of food, cocoa, from the fact of its being especially the diet of the invalid, should be above *suspicion* of having any deleterious admixtures; and yet, what have people been drinking of late years under the name of cocoa? what is the fact as revealed by the Analytical Sanitary Commissioners in their analysis of that article? Why! that out of the whole of the samples purchased at the different dealers in London, ONLY FOUR WERE GENUINE, ours being the best, being not only genuine, but free from husk and dust, and prepared with great care."

Arthur Hill Hassall, Esq., M.D., in his new work, "Food and its Adulterations," also makes favourable mention of our granulated cocoa.

We have been favoured with the following letter by the medical officer of the late Arctic Expedition:—

"GENTLEMEN,—I am requested by Captain Sir L. M'Clintock, R.N., to say that the cocoa sent on board by you was of the very best quality, and highly appreciated by all the ship's company, so much so, that it was preferred to that obtained from Beechey Island; and only twenty pounds have been brought home. In the travelling parties especially it was highly spoken of, and better could not be wished. Yours truly,

"DAVID WALKER, M.D.,
Surgeon to the Expedition.

"To Messrs. Handford and Davies."

In roasting the nut, fire is not allowed in immediate contact with the cylinder, but simply used to generate hot air, with which the nut is roasted; this is most important, preventing the nuts being scorched, which is often the case in the ordinary method of roasting—viz., placing the cylinder on a coal or coke fire, and thus preventing that rancidity so unwholesome and disagreeable, and so frequently met with.

"Those who are directed by their medical men to drink cocoa, with the view of renovating their strength, we strongly urge to make trial of our pure granulated cocoa. It is manufactured from the finest Trinidad nut with the greatest care, under a process peculiar to us; and we confidently state that it will be found more nutritious, easy of digestion, agreeable, and economical than any other."

This cocoa gave 5 per cent. of ash, and 42 per cent. of cocoa butter. In all other respects it agreed with the characteristics of cocoa.—*Genuine; good cocoa.*

16*th Sample.*—"BARRY AND CO.'S PREPARED COCOA."

Finsbury Steam Mills, London.

From Advertisement.

"The excellence of prepared cocoa."

"In offering this superior preparation of cocoa to the public, Barry and Co. do not give it any attractive name or puff of any kind to recommend it, but wish it to stand solely on its own merits, being a prepared or manufactured cocoa, from a combination of the finest Trinidad and Caracas nuts, the quality of which will bear favourable comparison with any other description of cocoa offered to the public."

---

[*] Many of the commercial so-called tin foils contain as much as 89 per cent. of lead, and only 10 of tin—such are more properly lead foils.

This cocoa gave 3 per cent. of ash slightly coloured. It contained about 52 parts of cocoa, 35 sugar, and 13 starch, the latter being arrowroot, with granules of potato starch. —*Largely adulterated with sugar and small quantity of starch.*

17*th Sample.*—COLLIER AND SON'S ORIGINAL PATENT COMMERCIAL COCOA.

Messrs. Collier and Son, London.

"Prepared from the finest Trinidad cocoa nibs by their much improved patent process."

This cocoa gave an ash which was coloured reddish brown, and which amounted to 3 per cent. This ash gave 21·5 per cent. of peroxide of iron. The specimen examined was mouldy, and contained *mucos mucedo.* It consisted of about 34 parts of cocoa, 24 parts of sugar, and 2 of starch, which starch seemed to contain granules of arrowroot, and potato starch and sago meal that had been submitted to heat.—*Largely adulterated with starch and some sugar, and coloured with ferruginous matter.*

18*th Sample.*—"THE MAIZENA COCOA."

Messrs. Dunn and Hewett, London.

The maizena cocoa contains only cocoa, maizena, and sugar, the "maizena" being "Duryea's," the only article of its kind which received a prize medal at the International Exhibition, 1862, with the award "exceedingly excellent for food."—*Vide Jurors' Report, Class* 3, *Sect. A.*

Report on Duryea's Maizena by DR. HASSALL.

"I have on several occasions examined samples made and imported into this country at different times, of the article so appropriately termed 'maizena.' I find it to consist of the perfectly pure farina of Indian corn, or maize, prepared in a peculiar manner. Regarded from a dietetic point of view, I am of opinion that this article in every respect equal, and in some particulars superior to the best descriptions of arrowroot, although sold to the public at a much lower price.

"ARTHUR HILL HASSALL, M.D. Lond."

Dec. 12, 1862.

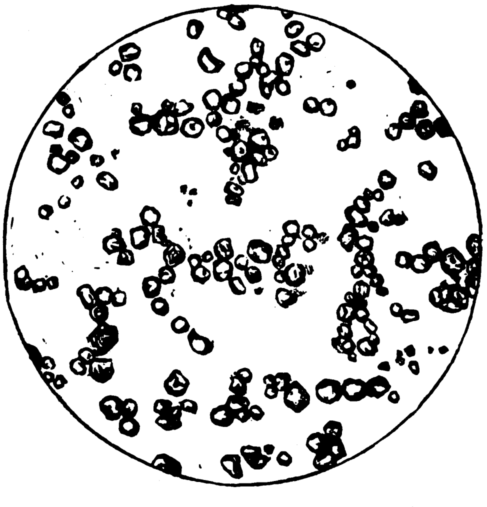

Fig. 4.—Indian corn or maize starch, 200 diam.

This cocoa gave 2 per cent. of a nearly white ash. It consisted of about equal parts of cocoa, sugar, and the starch from Indian corn or maize.—*Genuine, being exactly what it is labelled.*

19*th Sample.*—MARAVILLA COCOA.

Messrs. Taylor, Brothers, London.

"A success unprecedented! Maravilla cocoa is perfection. The *Globe* says: 'Taylor Brothers' Maravilla cocoa has achieved a thorough success, and supersedes every other cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla cocoa above all others. For homœopaths and invalids we could not recommend a more agreeable or valuable beverage.' Sold, in packets only, by all grocers.

"This beverage, while possessing the very highest efficacy as homœopathic cocoa, developes in an unrivalled degree the invigorating power, delightful aroma, and full, yet delicate, flavour of the nut."

Consists of about 54 parts cocoa, 34 of sugar, and 12 parts arrowroot.—*Largely adulterated with sugar, and also contains a small quantity of arrowroot; good quality of cocoa.*

(To be continued.)

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. THORNLEY STOKER, M.D., L.R.C.S.,
Demonstrator of Anatomy in the Royal College of Surgeons in Ireland

ADELAIDE HOSPITAL.

Case of Sclerema.

(Under the care of DR. BARTON.)

THERE is at present in this hospital, under Dr. Barton's care, a girl, aged nineteen years, who was admitted on the 27th of last April, suffering from the peculiar disease of the skin, to which the name of sclerema or scleroderma has been given. This affection, which is but rarely met with, consists in an indurated and brawny condition of the skin, which is hard and inelastic to the touch, and is free from any heat or redness. In this case, the girl had enjoyed good health until a few weeks before her admission to hospital. When she presented herself, the skin of her face, neck, shoulders, the upper part of her back, and of her chest as far down as the upper half of the mammæ, exhibited the diseased condition, while her right upper extremity was involved as far as the middle of the forearm. No other part of the cuticular surface was affected. The scarf-skin showed a disposition to peel off, and the tension and hardness of the diseased skin gave the girl's face a peculiar drawn expression. She suffered from darting pains, running from her neck to her shoulders and chest, and being sufficiently considerable at night, when they were worse, to deprive her of rest. She also complained of itchiness, and suffered from occasional attacks of vomiting. She had entered hospital not so much for the skin disease, as for an affection of her throat, which seemed to have some connection with it. She had lost her voice, could only speak in whispers, and complained of pain in swallowing. Examination showed a thickening of the fauces and velum, which were streaky and red, and the laryngoscope revealed a partial closure of the rima glottidis, and thickening of the vocal cords. There was no history of any constitutional disease.

She was ordered grain-doses of grey powder, with two grains of Dover's powder, three times daily for a few days, and under this treatment she recovered her voice completely. She was then rubbed night and morning over the affected parts with the liniment of mercury, and put upon chlorate of potash and bark. She has now been nearly a month in hospital, and was three weeks affected before admission, and besides having recovered her voice, seems to have derived considerable benefit from the treatment; her skin is less tense, and her features have lost, to a great extent, their drawn look, while the pain has almost entirely disappeared, and she can sleep at night. We forbear giving more particulars of this case, as Dr. Barton purposes publishing it at length. It is in one feature probably unique, for although a report of several such cases may be found in various journals (see "Guy's Hospital Reports," 1867), yet the throat affection is a complication hitherto unnoticed in connection with this strange disease.

◆

JERVIS-STREET HOSPITAL.

A new method of procuring extension in fractures of the femur, devised by Mr. Stapleton.

Mr. Stapleton drew the attention of the class to a novel mode of putting up fractures of the femur, which he had devised, its chief merit being that it did away with the necessity of using a perineal band, which, particularly in the case of children, rendered Liston's long splint a less advantageous apparatus than it otherwise might be. Owing to the restlessness of young children, the perineal bandage became readily loosened, and the splint displaced, the perineum also becoming excoriated and sore from the constant friction and pressure of the band, which very generally became wet and ropy. The perineal lac had also, he said, a great tendency to assist in displacing outwards the lower end of the upper fragment—a deformity which, owing to the powerful action of the external rotator muscles, is particularly likely to occur in cases where the femur is fractured high up, just below the trochanters.

His plan, the successful result of which he instanced in the case—that of a child, three years old—lying before them, but which he conceived could as well be adopted in treatment of the accident in adults, is as follows:—

A strong tape, more than twice the length of the Liston's splint, is taken and laid along each side of the splint, being passed through the hole in its upper end, and the extremities being tied together at its lower or notched end; the ends of the tape are left sufficiently long to hang over the foot of the bed, and to them is attached a weight, which must be regulated according to the amount of force to be employed. A broad strip of adhesive plaster is then placed along the inner side of the leg, from below the knee to the foot, and a similar one being fixed along its outer border; the two are knotted together a few inches below the foot, the point of the splint being passed through the loop formed by their junction. The upper end of the splint is then fixed to the body by a roller, and anterior and posterior scored splints having been applied to the thigh, the whole is enveloped in a many-tailed bandage. It will be seen that when the weight which is attached to the splint, and which, from the mode of its fixation, draws evenly on the splint in its whole length, is suspended over the foot of the bed, it will, by pulling on the plaster fastened to the leg and hitched over the fork of the splint, keep up a constant and even extending force, and will moreover, from the mode of its application, tend to hold the splint in position.

Mr. Stapleton considers that this is a practical point worthy of attention; that the danger of excoriating the perineum is done away with, that the splint is more readily kept in position on young children, and that the perineal band being absent, there is not the same liability to angular deformity by displacement of the upper fragment outwards.

ST. VINCENT'S HOSPITAL.

Blistering in acute rheumatism.

(Dr. Mapother's Clinique.)

Dr. Mapother exhibited to his class several cases of acute rheumatism which he had treated mainly by means of the blistering plan. He advocates this method of treatment very strongly, and has found it to afford much more favourable results than any other which he has tried. He stated that in some cases the patients express themselves relieved of the acute pain before there is time for any serum to be poured out; and this fact, if true, would he thinks, argue that the blisters act as counter-irritants to the diseased structures, and produce relief in that way. He is in the habit of using "Burt's blistering fluid" as a vesicating agent, and finds it a more certain preparation than any other which he has tried, being superior to the ordinary blister, owing to its rapid action. This preparation is sold in bottles of a very convenient form, a brush for its application is fixed to the stopper, and renders its use free from trouble.

◆

Transactions of Societies.

HARVEIAN SOCIETY.

Feb. 18, 1869.

President, Dr. Headlam Greenhow, in the chair,

W. F. Teevan, Esq., B.A., F.R.C.S., read the following paper,

PRACTICAL REMARKS ON THE TREATMENT OF GONORRHŒA, GLEET, AND IRRITABLE BLADDER.

Mr. Teevan divided gonorrhœa into two stages, the acute and the subacute. He was glad to say the abortive treatment had almost entirely fallen into disuse, as it was only occasionally accidentally successful, whilst, on the other hand, he had seen much serious injury done by it. In the acute stage nothing could be done beyond treating symptoms, though the duration of this stage might be shortened by rest, low diet, diluents, and hot fomentations. As soon as the acute symptoms began to subside, mild injections at once to be resorted to. They were generally prescribed empirically, no means being taken to ascertain what strength the patient's urethra could bear. Before ordering a patient an injection, he was in the habit of guaging the sensibility of the urethra by himself injecting a very mild solution, and gradually increasing it to such a strength as the patient could bear with comfort. He deprecated the use of copaiba, and said that as the disease was local, so ought the treatment to be. The injections he preferred were those composed of sulphate of zinc combined with the watery extract of opium, and tannin dissolved in glycerine also united with opium. Some patients could bear an injection of tannin ʒj. ad aq. ℥j. whilst others could only tolerate Zinci Sulph. gr.j. ad ℥j. aq. An injection ought to be thick and tenacious so that it might be retained for some time in the follicles and lacunæ. Regarding the treatment of gleet, the first point to be ascertained was, its duration. If it were more than six months old, no injection would be of any service, inasmuch as pathological alterations had taken place in the mucous membrane of the urethra, which could not be removed by injections. It was in this complaint the *Bougie à Boulè* was so useful, for it would give precise information regarding the pathological condition of the canal. The endoscope also was valuable, but inferior for hospital work to the former instrument. Having ascertained the state of the canal, a cure can be effected, occasionally, by deep injections applied through an elastic catheter attached to a syringe, but more usually by gradual dilatation, which might practically be called the preventive treatment of stricture, because in a gleet of more than six months' duration, there was always incipient contraction, the result of organic change.

There was no such complaint *per se*, as "Irritable Bladder"—the irritation was always secondary, the cause being local, the most fertile one being stricture of the urethra in that stage of incipiency which was but rarely recognised or detected by surgeons. In this complaint the *Bougie à Boulè* was invaluable for diagnosis. Mr. Teevan concluded by enumerating the various local causes of irritable bladder and the means to be adopted for their removal.

Mr. GASCOYEN complimented Mr. Teevan on his address, and although he agreed with him in some things, yet he differed in others. He believed there was such a complaint as irritable bladder, and instanced cases of irritability of the bladder in old gleets. Mr. Gascoyen also could not understand how the *Bougie à Boulè* could detect a stricture in its earliest stage, because, although the meatus externus would admit a No. 14, yet the bulb would take a very much larger size.

MR. BERKELEY HILL was glad to hear that Mr. Teevan did not give *cubebs* nor *copaiba*. He was of opinion that tannin was about the very worst injection, and he did not see how the *Bougie à Boulè* could detect minute strictures.

DR. BALLARD would be glad to know Mr. Teevan's experience of cubebs and copaiba, as he though they were very valuable remedies. He believed there were cases of true irritability of the bladder.

DR. OWEN instanced as examples of true irritability of the bladder those cases of students waiting their turn for examination at the College of Surgeons, who had urgent and frequent calls to urinate.

MR. TEEVAN then replied. He still maintained there was no such thing *per se* as irritability of the bladder. The case mentioned by Mr. Gascoyen was simply a case of irritability secondary to incipient stricture, and that referred to by Dr. Owen, was an example of a physiological law, the tendency of a muscular organ to expel a foreign body, which in the case cited, was the presence of urine of an abnormal specific gravity, and could no more be called an example of irritable bladder than could the efforts of the eyelids to expel subjacent grit be named "Irritable eyelids." Although it was quite true that the meatus externus was much smaller than the bulb, yet a No 12 *Bougie à Boulè* would detect any stricture inasmuch as it must be remembered that the urethra was not a patent tube, and the mucous membrane was always intimately in contact with the smallest instrument introduced into the canal.

A vote of thanks was then passed to Mr. Teevan for his address.

THE SURGICAL SOCIETY OF IRELAND.

THE concluding meeting of the Society for the present Session was held on Friday evening, the 20th April, in the Albert Hall, Royal College of Surgeons. The President of the College, Mr. G. H. PORTER, in the chair. The following members were present :—

B. Wills Richardson, Hon. Sec., M, B. Ward, R. Persse White, Hamilton Labatt, W. Thornly Stoker, A. H. McClintock, Thomas Purcell, E. J. O'Grady, J. Morrogh, M.D., Jonathan Leech, John Cronyn, M.D., G. B. Owens, M.D., Frank Thorp Porter, Edward P. Wright, G. G. Montgomery, Henry Kennedy, William Jameson, J. Jameson, G. S. Buchanan, Richard Bookey, George H. Kidd, William Roe, H. H. Stewart, Charles Robinson, A. MacAlister, Denham, Charles Benson, Hon. Sec., John H. Benson, John Morgan, MacNamara, Vice-President, D. B. Hewitt, Peter Shannon, A. H. Jacob, H. G. Croly, Henry Coulton, M. H. Stapleton, Edward Hamilton, C. Fleming, Frederick Kirkpatrick, J. Tufnell, R. W. Harley, B. F. McDowell, and C. F. Moore.

MR. MORGAN read a case of

TRAUMATIC TETANUS, SUCCESSFULLY TREATED BY NICOTINE IN SMALL AND FREQUENTLY REPEATED DOSES.

Joseph Preston, aged fifteen years, a healthy, intelligent boy, was admitted to Mercer's Hospital under my care, on 4th March, 1869, suffering from a compound and comminuted fracture of the great toe. He was a lithographic apprentice, and had been working at the machine, which, being inadvertently set in motion by himself, the eccentric rod in its movements caught his foot, crushing the boot, and the toe giving way at the same time, he fell backwards and was extricated at once and brought to the hospital within a quarter of an hour. The Resident at once put the foot into neat coaptation and dressed it with carbolic acid and oil. The case presented no unusual symptoms. On the 5th day I removed the toe, which had lost all vitality.

For the seven succeeding days the patient went on well, no unusual pain being complained of. Ext. opii. and water being applied, and the wound kept clean and dressed constantly.

On the 17th March, I observed as he was attempting to eat some boiled bread and milk, that he had some difficulty about managing it, and also that the tetanic countenance was slightly shown. He said he had not slept well, and he thought he had "caught cold," there being some soreness in swallowing. He was able to raise himself in the bed, and said he felt "all sore." Pulse 90 ; respiration 20 ; there being every evidence of the early appearance of tetanus. I desired him to lie very quiet. I had screens put round the bed, so as to prevent the least disturbance. A fœtid turpentine enema administered at once, and the following pill every three hours. Camphoræ gr. ss. Pulv. Opii. gr. ¼ ; Calomel gr. j. Pil. Rhii. Co. grs. v.

Evening of 17th.—Symptoms much the same, the bowels have been freed since morning. I had another fœtid turpentine enema administered, and the pills to be continued every three hours.

March 18th.—Symptoms hardly increased. Pulse 94 ; respiration 20 ; surface warm ; the expression the same, evidently tetanic ; being a thin lad the visage with the angles of the mouth drawn down was evident. Bowels moved but once. I had again a fœtid turpentine enema of sixteen ounces administered, which caused a copious evacuation of a healthy nature, not presenting the dark nor offensive characteristics. Pills continued every three hours. Beef-tea and wine given freely.

March 19th.—Symptoms rather more urgent ; the forehead and eyes have the peculiar contracted look of tetanus, and the general tension of the muscles is increased, particularly evident over the abdomen ; can open the mouth about half way. Pulse 108 ; respiration 22 ; has slept but little ; the wound is rather painful. There is no nerve exposed, or any special point of tenderness. Bowels have been well-freed ; urine normal, in quantity and constitution. There is a faint mercurial odour of the breath. The ice-bag was now carefully applied along from the vertex to the loins. This brought down the pulse by 10 to 16 beats, and the application proved most grateful to the patient, so much so that when the cold failed, he immediately asked for its re-application. There is a slight relaxation of the general tension. Pills to be continued every four hours ; wine and beef-tea freely given ; he is able to swallow, but with difficulty.

March 20th.—The condition much the same, the ice-bag seems to have lost its effect ; the pulse has gone up to 120 ; and respiration 24. The mouth is more closed ; but there has been as yet no regular spasmodic attack ; the general treatment continued, larger charge of ice being used with the bag.

March 21st.—Four days after the first appearance of the disease, evidences of spasmodic fits first showed themselves. During sleep the tongue being protruded and snapped between the teeth; the muscles of the jaw becoming now so tense that a wedge of wood is introduced to keep the teeth apart. He complains of a severe dart occasionally, not from the xiphoid region, but from under the left axilla towards the spine, corresponding to the upper dorsal region, there is no tenderness on percussion. Opisthotonos is now so marked that the arm can be passed under the body without touching it, the general rigidity of the muscles is increased, and the spasms of the muscles of deglutition, when an attempt at swallowing is made, are severe. Having given the ice-bag full trial, and the symptoms were undoubtedly steadily increasing in intensity, I now determined on the careful use of nicotine. The pulse being 124 ; respiration as high as 28 ; muscular tension universal, and the spasms, specially of the larynx and throat, threatening a rapid death from suffocation, the sensation of choking being the chief one complained of by the boy. The bowels had been thoroughly cleared, the influence of mercury had been brought to bear, and anti-spasmodics in the shape of camphor and opium had been fairly tried. I commenced on the mid-day of the 21st, the use of the one-twenty-third of a drop of nicotine ; five drops of liq. morph. every three hours, which was given in a little wine. The first two doses did not seem to have much influence, but at the third, in fifteen minutes after the adminstration, he felt sickish, and got even paler than he had been ; the pulse came down six beats, and the respiration four ; the abdomen tension somewhat diminished. During the night he had three violent spasmodic attacks, and one during the day.

March 22nd.—The muscles still rigid, though somewhat relaxed. It is remarkable that in about *fifteen minutes after each dose he falls asleep for about ten minutes, and the tension,* certainly decreases. The stomach is inclined to be sick directly afterwards. Pulse now 100 ; respiration 22.

March 23rd.—As he has become now more tolerant of the medicine I increased it to one-eighteenth of a drop every four hours with good results, and without causing sickness. The jaws remained rigid, the gag has still to be used, but he can remove it at times. Pulse now 96; respiration 20. He says he is now in less pain, and freer from the spasm of the throat muscles.

March 22rd.—I now increased the dose to one-fifteenth part of a drop every four hours, with five of liq. morph. the tension of the muscles now showed evident relaxation; he was able in the evening to draw up his legs, which gave him relief as the muscles were extremely sore, the muscles were relaxing, and he could swallow fluid in jerks by mouthfuls. The mouth can be opened about half way.

March 24th.—The symptoms are gradually yielding, the patient cannot dispense with the gag, but is able to turn on his side and move the legs. The nicotine was continued.

March 25th.—Gradually better.

March 26th.—From this date diminished the nicotine to every six hours, and from then I considered him safe; being six days under the influence of nicotine. The boy was much reduced, the flesh, emaciation, and debility.

[The following communication was received from Mr. Babington, of Londonderry, since the night of meeting:—

"In the tetanus case the nicotine was given up owing to the frightful depression, not that it was unmanageable. The dose I gave it in was one-third of a drop. He got two doses the fourth day at intervals of six hours. The second dose prostrated him very much, and caused cold sweats and vomiting. The patient was aged twelve years, and of weakly constitution. He had draughts, every three hours of cannabis indica, Battly's sedative, and water. Eighteen hours after second dose of nicotine, I gave him another dose one-third, and repeated it in six hours, the same symptoms as before occurred. I did not give him another dose but continued the draughts and fed him well with eggs, brandy, beef-tea. I am quite sure that I gave the nicotine in too large doses in this case, but not in larger than I have administered in three cases formerly, all of which ended fatally. In that case I fomented the spine and stomach with tobacco leaves. The case was idiopathic, caused by exposure to cold and wet."]

The President was sure they would all agree with him that this was a most important paper. The treatment of tetanus was perhaps one of the most important subjects that the surgeon had to deal with, and he would be glad to hear any remarks from the members of the society on the question of treatment by nicotine, which he believed had not been used very frequently in this city.

Mr. Tufnell said he had used nicotine in the treatment of tetanus on three occasions, twice successfully, once unsuccessfully. They were all cases of traumatic tetanus, and the doses he used were the drop doses recommended by Dr. Haughton. The great difficulty he experienced was in getting the patient to swallow the dose; the aversion of the patient to take it was intense, and it had almost to be forced into the mouth, and got down by trickling. He thought if the statistics were carefully taken of the recoveries by nicotine—he would not use the word cure—and by other means it would be found that the nicotine had been the most successful. The unsuccessful case to which he referred was that of a gentleman who was shot through the hand, and it was very far advanced when he was called down to see the patient in consultation with Mr. Wallace. One of the other cases was that of a compound fracture of the radius of the right arm. He was treated successfully by nicotine for the tetanus, but the moment any attempt was made to treat the fracture and to bring the bones into opposition there was a return of the spasm. Three weeks after the occurrence of the accident, and after recovery from the tetanic symptoms, as there was a good deal of deformity he attempted to replace the bones in their normal position, but the moment he did so the spasms returned, although the tetanus had fairly subsided. With regard to treatment by chloroform, he had had experience of one case when the individual was eight days and seven nights continually under the influence of chloroform, and then recovery took place. It was the case of a boy, who was standing on the top of a basket placed on the top of another, and endeavouring to take down a hank of onions suspended from the ceiling. The basket slipped, the hook passed between the ring and the little finger implicating the nerve and traumatic tetanus supervened. He recovered, and during the whole time of his illness he was continually under chloroform and plenty of nourishment.

(To be continued.)

Literature.

MR. SQUIRE'S LAST EDITION.

Less than a year ago we were commending the sixth edition of Squire's *Companion to the Pharmacopœia*, feeling that the work had arrived at a state that would probably be permanent. But Mr. Squire is less easily satisfied with his production than the great army of purchasers who have so rapidly bought up all he has produced, and now that a seventh edition has been called for, he has again revised it, removed the blemishes he alone detected, and added considerably to it.

Surely now that the edition has received the imprint of the perfect number—seven—we may look upon it as so perfect, as to be for a considerable time, permanent. We may be excused for hoping so, for it is rather annoying to find all one's stock phrases of praise exhausted by a single author who hurls at us remorsely, edition after edition—every successive one containing some improvement or other, which we were not shrewd enough to suggest, but of which the author has seen the desirability, if not the necessity. What is the critic to say to such an industrious man as Mr. Squire?

We intended if ever we found in the course of using it, a defect in the sixth edition to take a note of it, in order to come down upon Mr. Squire in the seventh, when he reached that golden epoch. But here he is upon us already, before we have recorded such a note against him, and coolly pointing out in his new preface some additions and improvements that he has made without our promptings. Well, what are they? First a tabular account of organic materia medica. Then, instead of the table of comparison between the Fahrenheit and Centigrade thermometers, to which we only had occasion to refer once in the former edition and found it suffice, we have now a more complete one including Reaumur. This is certainly an improvement. Again, there is now introduced for the first time, a concise account of the mineral waters. Here we turned to trip up the indefatigable author; for the mere compilation of such an account is no easy task, and our visits to the many Spas of Europe enabled us to look for some of them that ought to be included but might escape. Great Britain we took for granted, and turned to Cauteret, and Plombières in France, only to find them. In Germany leaving Hamburgh, Wiesbaden, and others so notorious, we looked for Gastein, Reichenhall and Ofen. All are here, so in despair we try Italy, and going far enough at first look for Ischia as a reminiscence of our Neapolitan tour and find the Gurgitello spring duly recorded. Lucca on the way home is also named, and those who think of a trip to Corscia will, on reference, find the character of the chalybeate saline water of Orezza duly chronicled, while those who do not like to venture on the voyage will see that the remedy can be had without going, as it is imported, which reminds us that in each case Mr. Squire gives that useful piece of information, and then at the end, adds a list of those mineral waters that "have been imported in bottles." Now after this trial what can we say of Mr. Squire's new edition? It does what it professes well, and bids fair, not only to be the indispensable companion to the Pharmacopœia, but actually to supersede the official formulary. Let the Pharmacopœia committee look to it, even now they have but a few of the spare leaves of Mr. Squire's laurels to wear. Let the General Medical Council ponder well this. At a fearful outlay extracted from our poor profession, they produced a national pharmacopœia. With that for a basis, Mr. Squire has produced a much more complete and more serviceable volume, without entailing on the profession a farthing of expense.

The seventh edition is of course, somewhat larger—fifty pages or more of new matter add somewhat to the thickness. It is the tendency of such works to grow, and we may almost hope it will stay here, for we are not enamoured of bulky books. The new edition is in this respect, a most desirable work, a really handy volume that will find its place beside every prescribers's desk, and on every dispenser's counter.

We have only to give Mr. Squire formal notice that if, in the course of our constant references to his work we come across any defect, or any improvement should suggest itself to us, we shall avenge ourselves upon him by returning to the subject, and redeeming our reputation for critical acumen of which he bids fair to deprive us.

WEDNESDAY, JUNE 2, 1869.

THE ABUSES OF GENERAL HOSPITALS.

WE have heard so much lately about special hospitals—our medical contemporaries have been so unmeasured in their denunciations of these institutions, and so fulsome in their adulation of the larger ones—that an account of the abuses of the latter comes upon us with all the freshness of a complete change of the current of thought. We heartily welcome, therefore, a pamphlet which Mr. Wilkinson, the Secretary of St. Mary's Hospital, has had the courage to issue, under the significant title of "General Hospitals, their Uses and Abuses: with some Suggestions for Applying a Remedy." It will, of course, be imagined that the object of the pamphlet is not exactly to attack general hospitals, but rather to illustrate, from a non-medical point of view, the objects of such charities, and show how far they at present fulfil those objects. Mr. Wilkinson seems to us to have written with a just appreciation of his subject, and to have accomplished the difficult task of the critic to

> "Nothing extenuate nor set down aught in malice."

His pamphlet is, therefore, worth the attentive consideration of the profession and the public. We propose now to lay before our readers his views.

First, as to in-patients, Mr. Wilkinson does not subscribe to the favourite notion that hospitals are for the *destitute* sick; he would consign such to the parish infirmary. Labourers and artisans, who can earn from eighteen to thirty shillings a week, and who form a large proportion of the in-patients of most hospitals, are, he considers, very proper persons to be received. Domestic servants, on the other hand, he would rather see provided for by their masters and mistresses; but so long as they not so cared for, they are proper cases for admission. But Mr. Wilkinson testifies, and we know that others in similar official positions could corroborate him, that tradesmen and others with means that ought to make them ashamed to receive charity, do often occupy the beds of hospitals. A very common cause is that they want to evade the fee for some surgical operation. Sometimes this, he thinks, arises from the large fee expected; but he suggests a remedy which we thoroughly approve—viz., that the surgeons should not introduce such cases into hospitals, but if the patient cannot afford the fee under which a leading hospital surgeon ought not to operate, that the case should be left to a junior. We happen to know that surgeons of high reputation have taken into hospitals, for the purpose of operating upon, persons in very good position, but who could not perhaps pay the highest fees. Now, this is a gross injustice to the younger surgeons, to whom such cases ought to fall. The hospital men are, in fact, by so doing, robbing their poorer brethren—not seldom, we fear, even of bread. The idea of exclusive talent or skill cannot be entertained. There are young men amongst us equal in these respects to any of their seniors, but who are thus constantly deprived of their patients.

We protest against such injustice. We rejoice that a non-medical witness like Mr. Wilkinson can support us in our protest, and we thank him for the manly and sensible mode in which he has stated the case. When we hear that Mr. Wilkinson has been consulted as to the propriety of admitting a person having an income of £300 a year, and that subscribers have wanted to give themselves letters of recommendation, it is surely patent to all that the abuse of unpaid medical advice has gone far enough. No wonder the profession is so poor—that every now and then some of its members sink into absolute want, that its widows and orphans are unprovided for. The mania of unpaid medical services has sapped the foundation of independence on the part of the people, and brought the medical art into contempt, and its practitioners to the condition of the poorest class of educated gentlemen. Let no more such follies be sanctioned. Rather let those who have achieved success see to it that they do not injure those who are still struggling.

Turning a moment now to the out-patients, Mr. Wilkinson finds the abuses arise from two classes—those who can well afford to pay for medicine and advice, and those who can partly do so; and he proposes a radical remedy. Those who could pay should certainly be excluded from relief; he would like to see those who can only pay a shilling or eighteenpence no longer asking admission to hospitals, nor "content to trust to the doubtful issue of a dose of medicine from the chemist's shop." Provident dispensaries would partly meet the case, but could only benefit the few medical men connected with them; while, in Mr. Wilkinson's opinion, "the best mode of dealing with the difficulty would be for respectable qualified practitioners to consent to see poor patients at a certain time in the day for a shilling or eighteenpence each." The fact of this suggestion is enough to show how great has been the abuse of medical charities. There are many "respectable qualified men" who would gladly act in this way—there are others who, because such practice is taken from them by hospitals, are driven to compete with the chemists, but who would infinitely prefer such a practice to retail trade; and the sooner such cases are curtly refused hospital charity the better for the profession and for those institutions.

Such persons being thus provided for, the destitute being consigned to the parish, no one would really suffer were the "further remedy" boldly suggested by Mr.

Wilkinson to be tried—viz., the *abolition* of the out-patient departments. When provision is made for those who now seek relief, Mr. Wilkinson would "be strongly disposed to recommend the closing of the out-patient departments of our hospitals, and leaving these institutions to their natural work of attending to the in-patients, and such cases of slight accidents or injury as would naturally apply for assistance as *bonâ fide* casualties."

With such an enlightened view as this, we hope soon to see something accomplished towards removing the abuses under which the profession suffers, and the people are becoming semi-paupers. A little judicious pressure would, we should think, diminish the evil by at least one-third, perhaps one-half. If Mr. Wilkinson could devise a mode of applying such pressure, and would try it at St. Mary's, he would add vastly to the obligations under which he has laid the profession by publishing his suggestions.

◆

TREATMENT OF TETANUS.

Having lately heard the report of a case of tetanus successfully treated by nicotine, administered in small doses by Mr. Morgan, in a traumatic case under his care at Mercer's Hospital, and Dr. Babington, of Londonderry, having reported another in which nicotine was given in larger doses but owing to its depressing effect had to be given up, and the patient finally did well, it is interesting to find that another powerful agent, the tinct. of aconite has been used also with success, by Professor Winderlich. As reported in *L'Union Medicale*, he gives the following :—

Case 1.—A boy, aged fourteen, attacked with traumatic tetanus with opisthotonos, profuse sweat, and miliary eruption ; many of the general muscles, particularly of the face affected ; severe and frequent convulsions ; temperature nearly natural ; and pulse steady. Morphia in full does was given, and warm baths used. There was but a temporary improvement under this treatment. Ten drops of the tincture of aconite were given four times a day, equal to two grains of aconite. The symptoms improved, the pulse fell below the natural standard, and the temperature normal ; recovery soon followed.

Case 2.—A man, delicate and with diseased lungs, suffered from spontaneous tetanus, trismus and opisthotonos, spasmodic contraction of other general muscles ; convulsions and abundant miliary eruption and sweat ; temperature tensely febrile ; pulse a little increased ; an intercurrent phenomena did not increase the convulsions, but raised the temperature a little, from 38°5 to 38°6 (centig), the temperature soon fell to 37°7 (centig.) Morphine was administered by the mouth, and by injections. Chloroform was rubbed over the affected limbs, this produced a temporary alleviation. Five drops of tinct. aconite given three times a day, however, rapidly changed the condition of the patient, who recovered ; the temperature being 36°8 to 37°3 (centig).

Professor Winderlich draws attention to the temperature condition, and the facts that during the period of miliary eruption and sweat the heat was not specially raised, and that the tetanic contractions and spasmodic action of the muscles do not cause the elevation of the temperature which is so remarkable preceding death by tetanus ; as in animals where tetanus is artifically produced. Elevation of temperature is not caused by the violent contractions and muscular action. He is fain to attribute their elevation to the remedies employed in the human subject, for the cure of the disease. In the second case, the heat was normal till pneumonia supervened, and it may be concluded that when the temperature rises some complication has occurred, and that the temperature will form a criterion of the probable issue of the case if it remains natural or lower than natural it presents the best augury for success.

In three cases of fatal tetanus observed, the temperature never fell to its natural condition.

We recommend these observations for further enquiry. No doubt the two cases referred to by Professor Winderlich were not of the violent and acute character we meet with in our hospitals and occasionally in private practice.

Mr. Morgan's case read before the Surgical Society here rather bears out the temperature observations of Professor Winderlich, as in his patient there was hardly any increase of temperature, though no miliary eruption or sweat had appeared, and what is also interesting, that though a traumatic case, it is not of an intensely acute character, perhaps attributable to early treatment.

SCOTLAND.

DR. ALEXANDER WOOD'S LECTURE ON THE POOR LAWS.

An influential society has been formed in Edinburgh with the object of diffusing a knowledge of Pauperism and the Poor Laws. Its actual work commenced on Friday, the 21st ult., with a lecture by Dr. Alexander Wood. This lecture is the first of a series by eminent philanthropists, and deserves attentive study. The lecturer spoke with no doubtful emphasis, but looking his question boldly in the face, skilfully set forth his decided conclusion that the Poor Laws are to blame for many of the evils against which such an outcry has been raised.

Dr. Alexander Wood opened his lecture with the following words :—

> "The establishment of a Poor-law on logical principles demands as a postulate the truth of the following proposition :—'That the state is bound to maintain in bare subsistence every one of those who have been born within its limits, and who, no matter from what cause, have failed to be able to earn a maintenance for themselves.' If this postulate be untrue, then the Poor-law based on it must be false ; if the principle is subversive of the natural laws by which God is pleased to rule the world, then the Poor-laws must have set themselves in opposition to these laws ; if these natural laws have been so arranged as to educe certain moral qualities of our nature, then the laws which oppose them must have a tendency to do the opposite, and will be found untrue in their principle and immoral in their effect."

Feeling that there could be no middle course the lecturer went on to examine the question, and argued that whether the state be regarded from a Benthamite view, as a voluntary association and a mutual protection, or as a paternal or patriarchal arrangement the Poor Laws could not be justly maintained. The greatest happiness of the greatest number could not justify supporting a multitude slightly above the starvation point, propagating their race with great rapidity, and dragging others down to their own level. On the other hand regard the state as *in loco parentis,* and it is not right to give a stone for bread, a serpent for fish. Dr. Alexander Wood, carefully distinguishes between civil right and moral obligations. He readily admits the moral obligation to prevent a neighbour dying of starvation, but he denies the right of that starving person (or the state in his behalf) to help himself from his richer neighbour's store. It is well that this plain statement should be made, and we thank Dr. Alexander Wood for the distinct manner in which he has uttered it. The truths of political economy are continually set at naught by a number of well-meaning but ill-informed people, who have done much to sow pauperism broadcast through the land.

Need we add that the lecturer recognizes the christian duty as distinctly as the moral obligation of feeding the starving? But the Poor Laws have an evil influence. They check the impulses of the benevolent, and have a still more disastrous effect on those who are not ashamed to be thus supported.

"By an irreversible law," said Dr. A. Wood, "it is determined that labour is the only means by which wealth, smaller or greater, can be obtained, and wealth is the only means by which food and clothing, and shelter for the body and education for the mind, can be procured. 'He that will not work, neither shall he eat,' it is a plain and legibly written law. The effects of idleness are want and poverty; from these there is no escape unless the toil of one man is made, either voluntarily or compulsorily, to support the idleness of another. Such a contrivance is the Poor-law, and from its violation of this first principle we reap the most bitter fruits. Such a contrivance, also, is injudicious private charity; both teach men the false doctrine that bread may be eaten without the sweat of the brow; both therefore run counter to the plain laws by which the world is regulated. Hope and fear are the most powerful stimuli of industry; why, then, should we pass laws which weaken the one and destroy the other? Why should we let loose the army of sloth, improvidence, and vice to destroy the stores of the frugal? Why should we interpose to disarm of its natural consequences that love of indolence or that tendency to dissipation which is the most productive source of poverty or wretchedness? Why, by virtue of her very vice, enable the mother of a child of shame 'to compel the Courts of the country to do homage to her claim, making crime a passport to legal privileges, and glossing over the native unloveliness of vice by universally extending to it a public recognition?' It is a terrible reflection that the Poor-laws, which were intended to emancipate from distress, have only succeeded in emancipating from duty; that they have taught the poor improvidence for themselves and heartlessness to one another; that they have led parents to desert their children, and children in return to neglect their parents; that by exempting men from the operation of the first law of nature—self preservation—they have sapped the foundation of the prudential virtues, and opened the door to an unchecked indulgence in dissipation, debauchery, and crime. And not only has it proved a powerful agent in sapping the morality and deteriorating the character of those who have been exposed to its noxious influences, but it is sad that the very law which takes of the substance of the rich to bestow it on the poor should, instead of uniting these classes, have created a great gulf between them, leading the one to stand at bay, defending their inherited or acquired possessions against the boundless rapacity of the other; the other to regard with scowling and envious covetousness the possessions of their neighbours, a part of which an unrightous law has already given them a legal right to obtain. Another strong objecton to the compulsory support of the poor is, that it admits no distinction between virtue and vice in the recipient. If therefore, the vicious find that their criminal indulgence does not entail upon them those sufferings which the laws of nature provided as a check—if they find that there is no distinction between those who have been rendered poor by their own fault and those who have fallen into the same condition by the visitation of God—they naturally conclude that it is safe for them to indulge their pauper-producing propensities now, and trust to the public provision for the poor for the maintenance of themselves and their families hereafter. It thus appears that, whether judged by their own nature or by their consequences, whether by theory or by fact, the establishment of Poor-laws in any country, although intended to be beneficial, has had quite the opposite effect. From this we conclude that these bad consequences are not accidental, but inherent in the very essence of the laws, and that, therefore, they cannot be entirely removed except by a change in the nature and administration of the law."

The next point of the lecture was that wherever Poor Laws have been established a series of checks upon them have very soon become necessary. Of all these the workhouse test is the only one that the lecturer thinks has been of any real service, and he would retain the use of the workhouses for the incorrigble, idle and vicious, where rogues, impostors, drunkards, vagabonds, should be made to work, or be punished by the jail or the cat. He would restore out-door relief to the position it occupied in Scotland, before 1837, and would thus combine with it volunteer agency.

This was long done in Scotland, it is still in operation in Paris and Eberfeld, and might be found effective. The treatment of the sick is altogether another question. Having gone into many points of the greatest importance as to the cure of pauperism, Dr. Alexander Wood did not hesitate to address himself to the great question of prevention, as follows :—

"When we have thus disposed of all our chronic poverty, commiting the lazy, the impostors, the masterful beggars, the habitual drunkards, the confirmed paupers, to the poorhouse or the jail, as may best suit their individual cases—when we have removed the sick and ill from the noise of the workhouse, and placed them in hospitals, existing, or to be created, where they will have good nursing and medical care—when we have arranged to relieve at home suitably and efficiently that honest distress which would be contaminated by workhouse association, and injured rather than improved, by workhouse discipline, not 'half of our heavy task is done.' Believing that the true end and aim of an efficient Poor-law executive is to prevent pauperism rather than to deal with it after it has become a real power, we must ascertain its sources, and endeavour to cut off its supplies. This is to be done—1st. By the visitors forming a careful aquaintance with the class immediately above that of paupers, and by exhortation, advice, and if need be timely aid, preventing them from reaching that abyss into which so many fall, and from which so few are ever recovered. 2nd. By the visitors making it their especial duty, particularly in times of sickness and distress, to see that all, especially the bread-winners, were sufficiently nourished, so that they should not, from weakness of body, relapse into that state when continuous labour becomes almost impossible, and temporary and repeated recourse to stimulants almost a necessity. 3rd. As man does not live by bread alone, but as fresh air and pure water are essential, if he is to be maintained in a healthy condition, real guardians of the poor will see to it that all unwholesome dwellings should be improved, or, if that be impossible, shut up altogether. Above all, care should be taken that air and water, the great agents in purification, should be freely and plentifully supplied to all. 4th. As vice and bastardy form a large source of expenditure, and largely recruit the pauper and criminal classes, all houses where decency is outraged, and all overcrowding, which produce the same effect, should be swept away by the strong arm of the law. 5th. The work must be begun with the young; they must be dealt with while the mind is still facile, impressible, and the disposition pliable. 6th. The state should take these uncared-for little ones, and adopt them as her own. 7th. Let the expense of educating and maintaining the children on their behalf be charged against the parents as a debt; and if their slavery to intemperance is such that they cannot shake from off its galling chain, you must shut them up for protection and make them work both for their own and their children's bread. 8th. When we consider that neglected sickness among the working classes is one main cause of the increase of pauperism in this country, and that a large majority of the inmates of our poorhouses are there from bad health, we recognise the necessity of having the medical element largely infused into any system of efficient inspection. In addition to the medical inspectors, there should be a medical Commissioner in the controlling board, to secure that the recommendations of the medical inspectors are enforced, to protect the Poor-law medical officers throughout the country from the pitiless parsimony of the parochial authorities, who are perpetually curbing their efforts to improve the condition of their patients. This central board should be neither so small as to render it unable to overtake its duties, nor so large as to free its members from individual responsibility. It should contain no honorary members, but consist only of men paid for the efficient discharge of its duties. It should be charged with the superintendence of all matters affecting the health and well-being of the poorer classes. Its powers should be greatly enlarged, and should enable it to compel all unwilling local boards to do their duty in sanitary matters. As it is, the bounty of the State is denied to the industrious and lavished on the idle and dissolute, By this, prudential habits are discouraged or destroyed. While this continues, a State provision for the poor can never be dispensed with, and there seems no chance of our escaping from the meshes which it has woven around us. But let such alterations as have been suggested be introduced; let temperance and the prudential virtues be encouraged; let industry and self-reliance be promoted; let the chasm which now separates the upper and lower classes be bridged over; let the natural law by which we are all dependent on, and responsible for, duties to one another be restored; let the poorer classes have their homes restored with social virtue that the possession of a home ensures; and then, not suddenly nor precipitately, but only when the arch of social order is reconstructed – when the lower classes are rendered independent of extraneous support – may the weak and inefficient scaffolding of a Poor-law by which we have sought to sustain them, be utterly and for ever swept away.

◆

Notes on Current Topics.

Venereal Disease in Cochin China.

In a report by Dr. Jules Grinelle, from the *Union Medicale* on the Diseases of Cochin China, we find the following, which shows the great extent of this evil, and adds still more to the completion of ideas as to its absolute origin, the modifying influence of climate, &c :—

"Venereal affections for a large proportion of the diseases of Lower Cochin China, about one-fourth of the hospital or ambulance cases. Gonorrhœa is more obstinate and more likely to be complicated with orchitis, than in Europe. Bubos are very frequent, and whether the result of gonorrhœa, or of sores having a tendency to phagedenic ulceration. It is therefore necessary to avoid having much loss of substance, and depressing cicatrices, to escape this. The writer was in the habit of using several times a day frictions of mercurial ointment into the gland, when the skin became thin and discoloured, the lancet was introduced, and the interior brushed with a solution of equal parts tincture of iodine and water, and then bandaged neatly, this was repeated daily, and in ten or twelve days, the parts healed. The seton used with the bubos gave some good results.

"Phagedenic ulceration was even more likely to attack chancres than a bubo, specially sores on the frænum, on the outside of the prepuce, or on the dorsum of the penis, and so severely, that the entire organ or the greater part, was compromised, and consecutive complications were frequent, but secondary syphilis rare, the syphilitic development is much more rapid than in Europe."

This is remarkably confirmatory of the tendency to phagedenic ulceration observed in many tropical climates, often attributed to the use of of spirituous liquors amongst the sufferers. This can hardly be the case here, whether phagedenic sore is a special poison, or sown in a particular soil, or caused by mode of living, &c., are interesting questions, the rarity of constitutional evidences is also remarkable.

Patent Medicine Vending.

At the last meeting of the Pharmaceutical Society, Mr. Breton announced his intention of bringing this subject under the notice of the Society at its next meeting, with the view, if possible, of totally abolishing the tax payable for permission to sell patent medicines.

The President remarked that the question of patent medicines was under consideration in one or two quarters of the Government. He had once heard it proposed to double the stamp. There were many difficulties in the laws relating to this subject which the authorities would be very glad to have cleared up. They would like to consolidate the whole into one Act, so as to have a clear description of what a patent medicine was, and the duty to which it was liable. He believed the revenue from stamps and licences was about £90,000 a year.

Mr. Mackay said that it was a most desirable thing that the Council should move in the matter, with the view of not only getting an equalization of the patent medicine licence, but, if possible, of getting it reduced to the minimum sum of 5s. He was not at all displeased that the matter had now taken a somewhat official form, and he hoped it would be carried forward by the Society. It was a most anomalous thing that the same licence should be two guineas in some places and in others 10s. and 5s.

The President said he had seen the authorities at Somerset House, and the proposal he made to them was to equalize the license. He thought it might be fixed at one uniform sum of 10s., and in this case the revenue would probably not suffer from the change.

Mr. Haselden thought they lost sight of one point, and that was that if they reduced the price of the licence or abolished it, they would open the door to the sale of patent medicines by all sorts of persons. At the present time when patent medicines were growing beyond control, he should like to see not only the licence but the duty increased. If it were reduced, they would open the door to their sale by stationers, hatters, greengrocers, and others, and already co-operative societies were selling medicines without paying duty.

The Curability of Purulent Infection.

One of the most important questions in surgery was introduced last week, at the sitting of the Imperial Academy of Medicine, of Paris, by M. Alph. Guerin, and it elicited a debate which will probably be prolonged. The subject is the curability of purulent infection. The *Union Medicale* expresses its regret that the intention to raise the question had not been known beforehand, no one seemed to be prepared to treat of it, and the numerous academicians who have made the attempt, shewed plainly that they were taken by surprise. M. Guerin confined himself to a presentation of sundry preparations, and his explanation lacked precision and clearness.

The result of the discussion was, that all the surgeons who spoke, Mons. Guerin, Gosselin, Verneuil, and Broca, believe in the curability of purulent infection, and they all cited cases. What distinguished M. Guerin from his colleagues was, M. Guerin gave himself credit for cures of a particular line of treatment, while the other speakers attributed the cures either to some proceeding of which they were unconscious, or to circumstances which they endeavoured to explain. M. Guerin's remedy is sulphate of quinine in doses as large as four grammes a day. Mons. Gosselin, Verneuil, and Broca, however, had seen cases recover or die, whether they had taken sulphate of quinine or not, and M. Broca said it was illusory to believe in the efficacy of any one medicine, it was, in his opinion, to a certain line of treatment that confidence might be given, and that treament was alcoholic stimulation.

It remained for M. Briquet, the author of the best therapeutic monograph of our time on Cinchona, to plead the cause of the sulphate of quinine in purulent infection, and this Academician in a few very practical sentences, showed that the intermittent rigors of this terrible disease, were a powerful indication for the employment of quinine salts.

In the cases recalled by M. Guerin he thought he observed that the sulphate of quinine had a greater effect on the purulent infection, the less it produced such symptoms as singing in the ears, deafness, &c. M. Herard, however, considered this assumption to be contradictory to the commonest results of practice.

The discussion was renewed on Tuesday last.

Health of Dublin.

In the Dublin Registration district the births registered during the week ending May 22nd, amounted to 142. The average number in the corresponding week of the years 1864 to '68 inclusive, was 191. The deaths registered during the week were 146. The average number in the corresponding week of the previous five years was 166. Nine deaths were caused by fever, viz., seven by typhoid or enteric, and two by simple continued fever. Scarlatina caused ten deaths, diphtheria, croup, and measles one each. Eight children were carried off by convulsions. Twenty-one deaths resulted from bronchitis, seven from pneumonia or inflammation of the lungs, and six deaths were referred to lung disease unspecified. Phthisis or pulmonary consumption proved fatal in twenty-one instances. Four deaths were ascribed to hydrocephalus, or water on the brain. Heart disease was the cause of four deaths, and aneurism of one. Six accidental deaths were registered.

Effects of Temperature on the Muscular System.

M. Chononlevitch, of St. Petersburg, has recently published the results of a very important investigation on certain physical and physiological properties of muscle. He briefly summarises his conclusions as follows.

1. When heat acts on a muscle at rest, it produces two effects, the one physical and the other physiological. The physical effect is observed only between the temperatures of + two and + twenty-eight degrees centigrade. Between these limits the muscle acts under the influence of health, directly contrary to the effect on all natural bodies, it contracts by heat and expands by cold.

2. Above twenty-eight degrees centigrade, this purely physical influence is complicated with another action of a physiological nature. If the temperature be raised uniformly up to forty or forty-one degrees, a contraction is produced, of which the extent increases between thirty-five and forty-one degrees. The muscle is in a state which the author designates as "caloric rigidity."

3. If it be attempted to produce caloric rigidity in two muscles, one of which has been separated from the body two or three hours before the other, it will be found necessary to employ a higher temperature for the former muscle.

4. The volume of the muscle diminishes during rigor mortis.

5. The specific gravity augments under the same influence.

6. The absolute weight diminishes at the same time.

7. The volume of the muscle also diminish during caloric rigidity.

8. The mechanical tension of muscles causes also a diminution in their volume. This, according to the mechanical theory of heat, is in accordance with the succeeding fact.

9. In muscles, (principally living muscles), a certain quantity of heat becomes free, under the influence of mechanical extension.

Westminster Hospital.

The annual distribution of prizes to the Medical Students of the above hospital, took place on Thursday week last, and consisted of surgical instruments, medical and surgical works of standard value, and standard literary works of some of the best authors, including Hood, Tennyson, &c. The chair was occupied by Mr. John M'Clabon, who, at the close of the proceedings, announced his intention to offer a prize of five guineas next year, for "General Proficiency."

Sea Side Convalescent Hospital.

According to the report of the above institution just issued, which has been submitted to a general meeting, its monetary condition appears to be quite satisfactory. The year's balance is £245, which sum, when added to the reserve fund will represent about £2,250. During the year legacies to the amount of £2,000 have been bequeathed to it.

It is proposed to exclude from admission patients suffering from consumption and other diseases which generally prove fatal. The reason adduced to justify this step is pressure of applicants.

Sanitary Condition of the Borough of Salford.

Dr. E. J. Lyson, Medical Officer of Health for the Borough of Salford, has issued his report for the year ending December, 1868; from which it appears there has been an increase of 328 in the mortality for the year as compared with 1867. The number being 3,610.

Fifty-two per cent. (in numbers 1,893) were children under five years of age, of whom 1,173 had not attained the age of *twelve months;* 404 deaths he attributes to scarlatina, 373 to bronchitis; 367 to diarrhœa; 266 of the latter being under one year old. Phthisis comes next with her 281 victims.

The number of births for the year appears to be a shade higher than 39·41 per thousand, which it stood at in 1867.

The report has been prepared with much care and will prove invaluable to the statistician and the general reader.

Still, Saint Pancras.

The guardians of St. Pancras held a meeting on the 20th ultimo, to fulfil a pledge given by the majority of those who had been newly elected, which was to the effect that at an early opportunity the work put in progress by the late board in so far as it related to the intended schools at Leavesden, should be inquired into with a view to its discontinuance. The committee appointed to consider the subject reported that over £9,000 had already been paid to the contractor, that the distance from town of those schools was far too considerable (18 miles) and recommended that the Poor-law Board be applied to with a view to having the order given for the erection of these schools, rescinded. It appears the land had cost £13,000, the builder's contract £37,500 (which, with extras, would amount to £50,000), on which sum the ratepapers should pay interest. Mr. North, chairman of the committee, moved a resolution to the above effect, which was seconded by Mr. Parson, and supported by Dr. Collins. Dr. Edmunds moved an amendment naming a committee to reventilate the question and take evidence. Sir Sidney Waterlow seconded the amendment, which, on being submitted to the meeting, was lost. The original motion was carried.

The Church Surplus Funds.

THE following letter has been received from Mr. Gladstone, in reply to a letter from the Clerk of the Gort Poor Law Union enclosing resolutions adopted by the guardians in favour of appropriating a portion of the surplus funds of the Established Church in aid of workhouse hospitals and infirmaries, rather than in aid of county infirmaries:—

"10 Downing street, Whitehall,
May 14, 1869.

"SIR—I am directed by Mr. Gladstone to acknowledge the receipt of your letter of the 10th instant, enclosing a resolution of the board of guardians of the Gort Union, and to inform you in reply that there appears to be every reason to believe that the workhouse hospitals and infirmary are most useful institutions, and very well managed; but they are a direct charge upon the poor rate, and the preamble of the bill which has passed through committee in the House of Commons expressly declares that the surplus revenues of the Irish Church shall not be applied so as to cancel or impair the obligation now attached to property under the acts for the relief of the poor. With respect to the county infirmaries it is contemplated, before any aid is granted to them from the surplus, to improve their organisation, and render them more available for the class for whom they are intended; and the guardians will perceive that by relieving the county rates, either wholly or partially, from their support, the ratepayers will be more able to bear the charge of supporting the workhouse hospitals and infirmaries.—I am, Sir, your obedient servant, "ALGERNON WEST.

"Mr. James Slator."

The Water Supply of Dublin University.

PROFESSOR Apjohn and the Rev. Mr. Leslie have completed their analyses of several specimens of water, taken from the wells of Trinity College and its vicinity, and have published the results in a report presented to the Provost. The water examined has been taken from four pumps in different parts of the College, from a pump in Kildare street, at the corner of Molesworth street; from another in Creighton street, and from a seventh near Clarendon's Riding School. All of these pumps, with the exception of that at the back gate of the College, yield water so hard as to be quite unsuited for washing purposes and injurious to the health of persons of delicate constitutions. The most important constituents of these waters, however, in a sanitary point of view are the ammonia and the acid oxides of nitrogen which they contain. These constituents are well known to be products, in the first instance, of the putrefaction of organic matters containing nitrogen, and finally of its oxydation; and when they occur n quantity in a water, they prove its connection with he source of sewage, containing nitrogenous substances n some stage of decomposition. Such matters are highly eleterious in their action on the animal system, and it may be said with tolerable accuracy that the fitness of a water as a drink for human beings will be in inverse proportion to the quantities of ammonia and nitric acid which it includes. Of the seven pumps examined that in Creighton street was the worst, and that which supplies the College kitchen was nearly as bad.

The numbers in the subjoined table exhibit the fitness of the several waters which stand opposite to them:—

Creighton street water	0·95
Water used in College kitchen	1·00
Racket court pump-water	2·00
Water at Provost's House	1·63
Water from Kildare street	2·55
Water at back College gate	9·14
Water from Clarendon's Riding School ...	2·58

Sir Patrick Dun's Hospital.

WE published about six weeks ago a resolution arrived at by the Board of Trinity College in reply to the request of the physicians and surgeons of clinical hospitals in Dublin, that the compulsion on candidates for the medical degrees of the University to attend at Sir Patrick Dun's Hospital might be removed.

That resolution declared that the Board would be prepared to recognise the attendance at all clinical hospitals as soon as arrangements should be made for the devotion by the medical staff of Sir Patrick Dun's Hospital of their undivided attention to it.

At present two of its medical officers, Dr. McDowel, and Dr. Robert Smith, hold office also in the Richmond Hospital, and the following correspondence has taken place on the subject:—

"*To the Right Honourable and Honourable Governors of the House of Industry Hospitals.*

"Sir Patrick Dun's Hospital, Dublin,
"April 27th, 1869.

"My Lords and Gentlemen,—I am directed by the Board of Governors of Sir Patrick Dun's Hospital, to forward a copy of a memorial addressed to the Board of Trinity College by fifty-seven of the physicians and surgeons of the Clinical Hospitals of Dublin, together with two resolutions passed by the Board of Governors of Sir P. Dun's Hospital in reference thereto, and the final resolutions passed on the subject by the Board of Trinity College, on the 24th inst.

"As the Board of Dun's Hospital is unable to complete the arrangements for securing the undivided attention of their entire medical staff, without the co-operation of the Governors of the House of Industry Hospitals, they earnestly request such co-operation in order that both hospitals may be freed from the evils necessarily arising from the same persons holding Clinical appointments in the two hospitals; one of them also being at the same time physician to one hospital and surgeon to another.—I have the honour to be, my lords and gentlemen, your obedient servant,

"(Signed) "JOSEPH MULLEN, Registrar."

"House of Industry Hospitals,
"Dublin, May 6th, 1869.

"Sir,—I am directed by the Board of Governors of the House of Industry Hospitals to acknowledge receipt of your letter of 27th ultimo, in which the Board of Governors of Sir P. Dun's Hospital request the co-operation of this Board, in order that both hospitals may be freed from the evils necessarily arising from the same persons holding Clinical appointments in the two hospitals; one also being at the same time physician in one hospital and surgeon in another.

This Board fully agrees with the Board of Sir P. Dun's Hospital in opinion as to the evils necessarily arising from the same medical officers holding clinical appointments in two institutions. This Board had, however, no part in giving rise to those evils, for on the first occasion since the institution of the Board by Act of Parliament, when an election of medical officers to these hospitals was about to take place in January, 1868, when a surgeon from another hospital was among the candidates, this Board passed a resolution that no medical officer of these hospitals appointed then, or at any future date, whether physician or surgeon, should hold a Clinical appointment in any other hospital.

"The evils referred to in your communication have arisen from the appointment, either by your Board or by the Board of Trinity College, to the office of Clinical Surgeons to Sir P. Dun's Hospital, of two gentlemen at that time holding similar appointments in the House of Industry Hospitals, without communicating with this Board, or imposing any condition on those gentlemen as to their holding Clinical appointments in two Institutions.

"This Board would gladly co-operate with your Board in abating the evils complained of; but this Board does not see, nor does your letter point out, how such co-operation is to be carried into effect.

"I am, sir, your obedient servant,

"(Signed) JAMES WILSON HUGHES, Secretary, &c."

British Association for the Advancement of Science

Have issued a circular which announces that the meeting for the present year will commence inExeter, on Wednesday, the 18th of August next, under the Presidency of George G. Stokes, M.A., D.C.L., Sec. R.S., Lucasian Professor, of Mathematics in the University of Cambridge. As Exeter has never yet received a visit from the Association, the following information may be useful to many of its members. The population of the city is about 42,000. The hotel and lodgings accommodation in the city is quite equal to that of the majority of towns visited by the Association. Exmouth, Dawlish, and Teignmouth, watering places within about half-an-hour's journey by railway, have ample accommodation for visitors and their families. Exeter is about five hours' distant from London by the Great Western and South Western Railways, and is on the main line of railway to North and South Devon and Cornwall. Members proposing to make a tour through Devon and Cornwall should obtain tourist tickets, which will be supplied to any one member, on production of a card of membership, from all the principal stations in England. Tourists' tickets are available for a calendar month, and for a longer period by a small further payment. The journey can be broken at Exeter both in going and returning to North or South Devon and Cornwall. Members can obtain return tickets, available from August 16th to 28th, on production of their card of membership, at ordinary return ticket fares. Invitations have been already received by the Local Committee from the inhabitants of Plymouth, Devonport, Torquay, and Taunton, for the members of the association to make excursions into those neighbourhoods; and it is expected that excursions will be made to North Devon, Dartmoor, and other places of scientific interest during the meeting.

THERE will be a conversazione at the Royal College of Physicians, Pall Mall, on Wednesday next, the 9th inst.

BY a return just issued, we find the number of paupers in England and Wales have increased by 16,095, over the corresponding period of 1868.

THE University of Oxford on the 27th ult., granted £500 towards the erection of fever wards in the Radcliffe Infirmary.

A GRAND bazaar is announced in aid of the funds of the German Hospital, Dalston, to be held this day, tomorrow, and Friday. As will be seen by the announcement in another column, it is under distinguished patronage.

FROM a German paper we find that ophthalmia of a very contagious character has broken out in Berlin; precautionary measures have been adopted, as the profession in that City believed the malady to be of the same type as the terrible Egyptian Disease.

THE next examination for Matriculation, in the University of London, will commence on Monday the 28th inst.

There is a slight alteration relative to the Military College of Sandhurst, which will be seen on reference to our advertisement columns.

THE necessary advertisements have appeared announcing that a "meeting of the Fellows of the Royal College of Surgeons of England, will be held at the Hall of the College, in Lincolns-Inn-Fields, on Thursday, the 1st day of July next, at two o'clock in the afternoon precisely, for the election of three Fellows into the Council of the College."

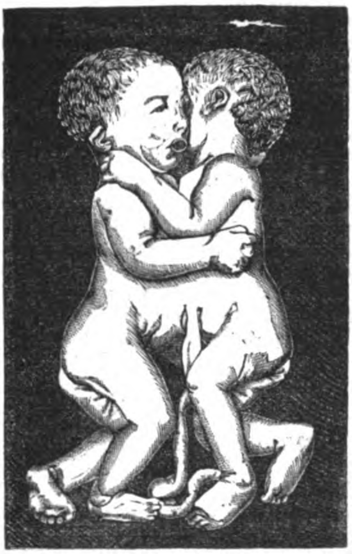
THE Prince and Princess of Wales, accompanied by the Crown Prince of Denmark, and attended by the Countess of Macclesfield, General Sir Willam Knollys, and Major Grey, were present on Monday at the "Annual View" of St. Bartholomew's Hospital, of which his Royal Highness the Prince of Wales is president.

AT Liverpool on Wednesday last, the magistrates imposed a fine of forty shillings upon a lodging house keeper for placing two lodgers who were suffering from small-pox, in a street cab for conveyance to the workhouse hospital. We cannot but rejoice at the decision of the bench to fine every person charged with like offences; and we hope the time is not far distant, when fever cabs, or hospital carriages will be found in every parish, accessible alike to rich and poor.

The famous Ribiri prize of 20,000 francs will be awarded for the the third time in 1871, by the Academy of Medicine of Turin. Our readers will recollect that this prize is given to the author of the best work published during the interval between 1868 and 1870, or of the discovery which shall have contributed to the greatest extent to the progress of medical science. Last year the prize was awarded to a German, Professor Brün of Tubingen, for his work on the laryngoscope. All the manuscripts must be transcribed in Latin, French, or Italian, and when a translation is sent in, it must be accompanied by the original. They must be sent into the Academy before December, 1870.

UNITED TWINS.

A brief notice of the fact of united twins being born in London, contained in our last issue, has proved of so much more interest than might have been anticipated, that we this week furnish an engraving of the twins, taken from a photograph courteously supplied to us by Dr. J. F. Rogers, the accoucheur in the case.



It should be stated that the union of two children is by no means so rare as some seem to imagine. Before the first exhibition of the Siamese Twins in England, in 1829, others had been publicly shown. The Hungarian Sisters, born in 1701, were much more remarkable. They were joined at the lower part of the loins, but in such a manner that they did not stand back to back, but half way inclined towards a position side by side. They were not perfect, as every organ was not double, one or two being destined for the use of both; one was an invalid, the other enjoyed fair health; one would sleep while the other was wide awake; one would be hungry or thirsty when the other was not; and so with regard to other functions they were quite distinct individuals. They died, however, almost together, at the age of twenty-two.

In the London Hospital Museum may be seen a specimen joined in front similar to that in our engraving to-day. In the same museum there is another specimen, joined by the back and sides; and others are preserved elsewhere.

Such united twins may be ranked as the more common kind of monstrosities. More rarely, individuals have been born and survived with a partially developed twin attached. Thus, a generation ago, a Chinese youth, said to be sixteen years old, was exhibited in London, who had a portion of a twin brother (consisting of the loins, arms, legs, &c.) so attached as to present the appearance of protruding from his stomach. Other instances are related on credible authority, in which the head of another body has appeared to grow out of the chest or some other part of an individual. There is an account of an analogous monster in the "Philosophical Transactions," vol. lxxix. The origin of such twins may be easily accounted for, and has been illustrated by experiments on the inferior orders of creation. We may add that the notion of maternal impressions, from the publicity given to the Siamese Twins, is only fit for a monthly nurse.

INTERN LYING-IN HOSPITALS AND EXTERN MATERNITIES.

The debate on Dr. Evory Kennedy's paper was renewed on Saturday evening last, with unabated vigour and interest, and, in anticipation of an address from Dr. Beatty and Professor Stokes, before a larger audience than ever. The President having taken the chair,

Dr. Beatty opened the discussion. He commenced by quoting the results of his own and his father's practice in respect of mortality from metria. His father attended 5,616 private labour cases. Of these, 13 had died; 2 from accidents of labour, 9 from puerperal fever, and 2 from non-puerperal diseases. Dr. Beatty himself had attended 2,064 cases, of which he had lost 17; 4 from accidents of labour, 8 from puerperal fever, and 5 from non-puerperal diseases.

Taking together his and his father's practice, they had had 30 deaths in 7,680 cases.

He proceeded to illustrate his view of the cause of metria by two cases which occurred within his own experience. In the year 1834 he had assisted the late Mr. Colles in an amputation of the breast, and had continued in attendance when the erysipelas set in. During the same period he was in attendance on a lady, who took puerperal fever and died. He was distressed to be obliged to acknowledge that he now believed he had unwittingly conveyed the contagion of erysipelas to this lady, and that it had developed itself in the form of metria. If he had done the same in the wards of a lying-in hospital, the result would have been the same in an infinitely greater degree. In 1855 he had attended another lady who suffered from external erysipelas, and after a week he had one morning observed that the nurse was absent, and was informed that she had been obliged to go to another lady. Within three days he was sent for to see another lady, and the first person he met on the stairs was the same nurse. The lady had taken metria, and was dead in forty-eight hours.

Dr. Beatty then proceeded to detail some cases from a most important series published by Mr. Seyde, of Edinburgh, in the year 1839. In the first, a lady had died of metria, and within a short period the servant had taken erysipelas and died, and the husband had suffered from an attack of fever and sore throat of an erysipelatous character. Each of the other cases illustrated the transmission of metria in the form of erysipelas to other members of the household, and even the communication of the disease to Dr. Imlack, the physician in charge, and, through the nurse, to persons outside the house.

Dr. Beatty proceeded to show that erysipelas and metria were convertible diseases, and proved, from the reports of the South Eastern Hospital, that when metria was epidemic so was erysipelas. In King's College Hospital, in the year 1867, out of 125 labours there had been 9 deaths, or 1 in 13·8 cases; and the mortality of six years was 1 in 28·9—a rate which, Dr. Beatty believed, was attributable to the location of the patients in a general hospital. He called special attention to the letter of Dr. Johnson, of Kilkenny, who reported that in his district metria was unknown, and so was erysipelas. He insisted that the relation between the diseases was not mere "resemblance," but absolute "identity;" and said that, though it might obviously be communicated epidemically, it might, with more probability, be spread by contagion. He combated Dr. Kennedy's view that its origin was proportionate to the number of patients congregated, for experience showed the direct contrary. There was no analogy for such a theory, and it was not possible to invent exceptions to natural laws to support special theories.

Dr. Beatty then proceeded to discuss the means of prevention. He said that no good surgeon would operate when erysipelas was prevalent, but as women could not postpone their operation, it was necessary to take every precaution to prevent infection. If she could do so, the mortality might, in his opinion, be absolutely stopped. But other means might be taken, and they were precautions on the part of the attendants. He believed fully that the great majority of cases arose from the transmission of the disease by medical students; if the risk of infection to many women be multiplied by the number of students, the wonder was that the mortality was not greater. He said that the class of students who now attended lying-in women were quite different from those who did so long ago, and the mortality had increased with the thirst for practical dissection. He would have the education in midwifery put off until after all other study had been concluded, and no student permitted on any account to enter a ward after contact with diseased or decomposed structures.

On the conclusion of Dr. Beatty's remarks, Dr. Stokes and Dr. Henry Kennedy addressed the meeting. We are compelled to postpone publication of their remarks.

The debate will be continued on Saturday next by Dr. Byrne.

Correspondence.

THE DEBATE AT THE DUBLIN OBSTETRICAL SOCIETY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The comments which appeared in your last impression relative to the proceedings of the Dublin Obstetrical Society call for some notice. Without doubt, the *prestige* of the Society was seriously damaged by the extraordinary oration which occupied the entire of the last evening; but it is most unjust to condemn the Society because one member is found capable of handling so serious a subject in a jocular manner. Surely you cannot accuse any one of the previous speakers of treating the subject in any but a becoming manner. This is, however, of comparatively little consequence compared with the insinuation conveyed in the assertion that the discussion had taken the form of "an overwhelming organisation for the defence of individual hospitals, and for the extinction of Dr. Kennedy." This I believe to be a most unjust insinuation, and one wholly without foundation. Is it likely that such men as Churchill, Beatty, M'Clintock, or Denham would be capable of joining in such a proceeding as the foregoing paragraph implies? the two former of whom were never in any way connected with either of the hospitals in question, but, on the contrary, were attached for years to small lying-in charities; while the two latter have no greater interest in them than Dr. Kennedy has himself—namely, that of being Governors and former Masters. The fact that such names as the foregoing must be included in "the organisation," if it existed, is, I think, sufficient proof of the incorrectness of the insinuation, but further, from my knowledge of the facts, I can without hesitation assert that no "organisation" exists or ever did exist; on the contrary, I believe that the great majority of the members of the Society have approached the subject with the most sincere desire of arriving at the truth. It was the duty of those gentlemen, who were practically acquainted with the working of lying-in charities, to express their opinion. Doubtless those opinions differ in many material points from Dr. Kennedy's; but, though almost every speaker proved some portion of Dr. Kennedy's statistics to be incorrect, and some of his conclusions erroneous, there was not one who attempted to say, as you would lead us to suppose, "that his facts and arguments had nothing in them." On the contrary, everyone admitted the truth of some of his "facts" and "arguments." Without doubt all the speakers were of opinion that Dr. Kennedy overrated the evils and under-estimated the good of lying-in hospitals, while some feared that the remedy he proposed, founded on insufficient, and, in some respects, erroneous, data, would prove a failure; and that, while it was easy for him to point out the defects of certain institutions, it was far from certain that the new plan would have fewer.

You say, "It will be a lasting regret and reproach if this debate goes forth from the Society without a word of independent opinion on the matter." Now, I would ask what is meant by "independent opinion?" Are not those eminent men whose names I have mentioned both independent, impartial, and above the suspicion of being actuated by unworthy motives? Has not the discussion been perfectly free? Has any impediment been thrown in the way of any member addressing the Society? Nay, more: has not the President on every occasion invited visitors to take part in the discussion? What greater freedom of discussion is possible? But if all the speakers have agreed in condemning some of the salient and novel propositions put forward in Dr. Kennedy's essay, or in exposing some inaccuracy, does it therefore follow that their opinion is not an independent one, or their unanimity "suspicious?" I regret trespassing thus on your space, but feel constrained to vindicate a Society, in the welfare of which I take a great interest, from what I believe to be unjust in your comments.

I am, Sir,

Your obedient servant,

A MEMBER OF THE OBSTETRICAL SOCIETY.

May 29.

[Although we cannot see that our correspondent's vindication of the Obstetrical Society was called for by any comments we have made, yet we insert his letter with satisfaction, because an opportunity is afforded us of repudiating his interpretation of our remarks. Our assertion that "the debate took the form of an overwhelming organisation" has been read by nine out of ten of our subscribers, we are convinced, as we intended that it should be,—in the sense that the general tenor of the discussion, the deliberate mode in which it was conducted, and the very remarkable unanimity of the speakers, was calculated to convey to the independent reader the impression that the speakers were biassed *pro* Rotundo and *contra* Dr. Evory Kennedy's views.

Whether this statement be or be not justified, it is equally unfair to us that our correspondent should attempt to apply our objection to the style of the debate to the speeches of individuals.

We can give expression to an opinion as to the tone of a lengthened discussion without charging any speaker with anything more than involuntarily contributing to that tone, and without in the least implying the existence of any organisation as it has been, we cannot swerve from our opinion, formed not without a patient study of the debate.

At the time when our comments were penned, eight obstetric members of the Society had, as far as we can recollect, spoken, of whom all but one were ex-Masters or ex-Assistant-Masters of the Rotundo Hospital, and of whom all, without exception, strongly condemned Dr. Evory Kennedy's opinions. Most of them were, we are convinced, unconscious of even a prejudice in the matter; yet, without doubt, the fact would be capable of an interpretation which it would have been better, if possible, to have avoided.—ED. M. P. and C.]

DR. DRYSDALE'S THEORY OF OVER-POPULATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In Dr. Drysdale's paper (in your number of May 5th) on the above subject, he speaks of preventing the miseries of over-population and starvation "by the prudent and common-sense practices of the French people." What are these practices? Let us have them fully set forth. Let us live with open windows. If they are "the best plan," if they are right to be done, they need not be hinted at, but should be explained to the profession, and made public.

Another word. What is thought to be a truth should never be half-stated. Either "dogmatism," "superstitions," "positivism," and the "true test of morality" are suitable subjects for discussion in your pages, or they are not. If they are, why not be more outspoken respecting them? but if not, then these passing flings at this or that creed are out of place and irrelevant to those things which are the proper subject of your periodical.

Finally, the title of this essay ought to have been, "Over-population, and how to prevent it," for that is what its author writes about. Among "causes of disease and early mortality" over-population ranks high, but so does intemperance, and so (*inter alia*) does the disgraceful state of the dwellings in which the poorer classes are compelled to live. While talking of over-population, let us not forget the two latter, which operate in a leading degree to sap and destroy the vital power of so many of our people, and which, if not speedily altered, must impair our national vigour.

I am, Sir,

Your obedient servant,

H. E. C. Nourse, F.R.C.S.,

Surgeon to the Brighton Hospital for Sick Children.

Brighton, May 31st, 1869.

◆

ON VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—We are aware from statistics, as from other experience, that since the discovery of the protective influence of vaccination, the fatality of small-pox has been considerably diminished; and it is now most probable that efficient vaccination confers a degree of immunity from that disease quite equal to that obtained by inoculation, while it is much safer, and by far less disgusting.

Though few physicians doubt the efficacy of vaccination in acting as a preventative against the contagion of small-pox, we should be loth, least, through carelessness in its operation (not being fully aware of the genuineness of the virus, and the healthiness of the party from whom it be taken), we should introduce into the system a disease equally as destructive. I think it may form a subject for discussion, whether or not phthisis and other diseases may not in this way be introduced into the blood of a healthy child. We know how diseases which lie latent in the system are brought out by vaccination. For my own part, as medical officer of a large district, I have taken lymph from children whom I believed at the time to have been perfectly healthy, but who had been previously affected with cutaneous diseases, and exactly the same eruptions were afterwards produced in healthy children who had been vaccinated with the virus. This has put me on my guard, having occurred in more instances than one, and in cases where (without previous knowledge) any one would say that the children from whom the matter was taken were in a perfectly healthy condition. It is also doubtful to me if the lives of one or two children were not caused by the introduction of tubercular matter, through the medium of vaccination, into their blood.

I must apologise for offering these few hurried remarks. I do not pretend to offer any theory of my own, my object being merely to elicit some observations on the subject from dispensary medical officers (more particularly from those located in country districts, who have more opportunities of judging of the after-effects of vaccination), with a view to understanding more thoroughly the dangers consequent on the introduction of unhealthy virus into the system, and whether or not hereditary diseases, such as phthisis, may not in this way be introduced into the blood.

I remain yours faithfully,

Richard Ambrose O'Kelly, L.R.C.P. Edin.,

Medical Officer of Dromleigh and Coolmountain.

May 15, 1869.

Medico-Parliamentary Intelligence.

The House of Commons resumed its labours the day after the Derby. Nothing of particular interest to our readers transpired on that day, and the attendence was small. On Friday last however, the Poor Act was on the orders of the day and Mr. Goschen moved the second reading of the Bill which he brought in some time back to amend Mr. Hardy's Metropolitan Poor Act of 1867. After explaining at some length all that had been done under that Act, he went on to particularize numerous considerations which made it imperative to proceed with the policy then commenced, costly though he admitted it to be. But the Bill, while giving greater facilities for amalgamation and classification, on the advantages of which, he expatiated very earnestly, would vary Mr. Hardy's progamme so far as to save the metropolis about £460,000. Among the most important points in the Bill he mentioned that it would give power to the Poor Law Board to dissolve small Unions and unite them with large ones, also to dissolve sick asylums and school districts in order to amalgamate them for other purposes. It would repeal all local Acts as far as the collection of rates goes, but its main feature was to obtain the great object of classification of paupers, not only sick but able-bodied, by amalgamation and exchange between different workhouses, rather than by new buildings.

At the close of Mr. Goschen's speech, the debate was adjourned until next Friday.

Medical Gleanings.

THE SUBSTITUTION OF SODIUM FOR PHOSPHORUS IN LUCIFER MATCHES.

The *Chemical News* describes the result of some experiments by Dr. Fleck, of Dresden, on the manufacture of non-poisonous matches by the use of sodium in place of phosphorus. The paste employed is composed as follows:—

Sodium	0·5
Nitrate of Potash . . .	66·0
Sulphide of Antimony . .	36·5

The sodium is granulated by agitation in melted paraffin, and incorporated with the other well-dried ingredients in metal mortars under petroleum. The necessary adhesiveness is given to the mass by caoutchouc previously soaked in light petroleum oil.

VEGETABLE PHYSIOLOGY.

In a paper addressed to the French Academy of Sciences, M. E. Faivre examines the part played in the white mulberry tree by the latex or descending sap. Physiologists are very much divided as to the real nature of its action. Is it a secretion? Does it constitute an alimentary residue, destined to undergo a new manipulation, so to say? Is it to be considered in the light of a serous liquid containing matter capable of assimilation, or is it a mixed compound, containing not only the latter, but likewise excretory substances? Such are the questions that are agitated, and in order to arrive at a reasonable conclusion, M. Faivre has very wisely confined his observations to a single plant, the white mulberry tree; and in this pursuit he has been engaged five years. Within the limits assigned he has arrived at the following conclusions:—1. The latex is *not* a transitory formation of the vegetable organism. In the mulberry tree it is found at every time of the year in the trunk, the roots, and the twigs. If any one of these parts be diseased or mortified, if it cease its functions normally, as is the case with the leaves, the latex diminishes and disappears. It abounds in the inner layers of the bark, where great vegetable activity prevails; it accumulates in large proportions at the base of each incipient bud, in the limbus of the leaves during their growth. 2. It is ascertained that, when cuttings are planted in winter in a hotbed, those which have wood-buds and containing a large quantity of latex, scarcely contain any as soon as the buds have opened; so that their development coincides with a diminution of that sap. The effects produced by the striking of the cutting become especially perceptible when the twigs just treated are compared with others taken on trees at the same period, and as much as possible in the same condition. The same results are not perceived in such cuttings as are laden with fruit-buds. 3. The connexion between active vegetation and the diminution of latex is also proved by the following experiment :—Let an annular excision be effected in spring on a ligneous twig, the buds being removed above the cut, and the existence of latex in the parts subjected to the operation being ascertained. All the buds or new leaves sprouting out above the excision should be carefully removed as often as any appear, and before their complete development. This done; on cutting off the twig, it is found that the latex has disappeared, and that the amylaceous deposit, the existence of which has been shown in the ligneous strata, has likewise, at least partly, disappeared. From all this and other experiments, M. Faivre arrives at the conclusion that the latex, though it may contain excretory principles, certainly plays a part in nourishing the plant.—*Galignani.*

THE TERMINATION OF THE SENSIBLE NERVE OF THE URINARY BLADDER. BY DR. M. PFLAUM.

EXAMINATIONS about the relations of the nerve in the mucous membrane of the urinary bladder, which I made last winter session under the direction of Professor Chryonsczewsky, were of the following results :—

I. The little nerve trunks of the sub-mucous membrane send off fine nervous twigs, or more frequently single nerve fibres, which pierce the mucous membrane in different directions, and finally terminate in the following double way :

1. Either the nerve fibres go directly to the deeper epithelial layer, where they change into piriform nuclei containing structures, or

2. They unite in the upper part of the mucous membrane to a horizontally arranged plexus, and from this are eliminated those fibres which unite with the piriform structure.

II. Against the epithelial nature of these piriform structures speaks besides their form the following :

1. In a solution of carmine they get more intensely coloured than the neighbouring epithelial cells, and

2. They adhere more strongly to the mucous membrane than the common epithelial cells.

III. They are on the contrary of nervous nature, which appears from the following :

1. Chloride of gold gives them, in the same way as to the nerve fibres, a dark brown or even black colour, whilst the surrounding connective tissue and the epithelial cells are not at all changed by it.

2. Every one of these structures is anatomically a continuation of the axis cylinder of a nerve fibre. This continuation became evident by the isolated preparations.

IV. Before the junction with these terminal apparatuses, the axis-cylinder often undergoes a dichatomous division.

V. The nerve shears disappears for the most part, still before the concerned fibre has reached the epitheial layer.

By this examination I availed myself of a solution of carmine, a solution of chloride of gold, and a solution of chronic acid (for isolating). I also made use of pencil and needle.

IRON SUGAR.

A NEW preparation of iron has been recently introduced into medicine by M. C. Chautrand, under the name of *Sucre Ferrugineux.* It is in the form of small distinct cubical crystals of cane sugar, having a reddish-brown colour due to the presence of a portion of peroxide of iron in a soluble condition diffused in and upon each crystal. When introduced into cold water it dissolves, forming a deep red solution, only a trace of the oxide of iron remaining insoluble. If the solution be boiled or kept for some time, the oxide is precipitated.

This preparation appears to contain nothing but a pure hydrate of peroxide of iron associated with the cane sugar. The proportion of iron present is not large, but the compound is pleasant to the taste, and is intended to be taken in doses of two to four teaspoonfuls half an hour after meals.

NOTE ON DISPENSING.

A RECIPE, the main ingredients of which were as follows, was directed to be prepared :—

℞ Potass. Chlorat. ʒss. ;
Sodæ Hypophosphit. ʒj. ;
Syrup. Simpl. ℥ss. ;
Aquæ *ad* ℥vj.

The salts, owing to pressure with regard to time, were mixed energetically together in a mortar. Explosion ensued with no other dangerous result than whirling the pestle to a distance, and slightly injuring the dispenser. The mode of compounding this and similar formulæ is to dissolve the salts separately, when no accident can happen.—*Pharmaceutical Journal.*

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—At the annual meeting of this society, Thomas Hammerton, Esq., M.P., in the chair, Henry Sterry, Esq., was elected a vice-president, and the following gentlemen directors, viz., Nathaniel Grant, M.D. ; Francis Bisset Hawkins, M.D. ; Henry Pye L. Drew, Esq. ; Erasmus Wilson, Esq. ; James Hinton, Esq. ; and Frederick G. Reed, M.D. The statement of accounts read showed a total of £2,504 10s. granted in relief during 1868, an increase of £261 over that of the preceding year. At the end of the year 52 widows and 27 children were receiving relief in sums from £50 to £20 per annum for the widows, and from £25 to £5 for the children. During the year 6 widows and 11 children had been added to those already on the books ; 6 widows receiving grants had died, and 2 children had become ineligible. The secretary stated that already, during the present year, applications for assistance had been received from 5 widows and 18 children. The meeting was brought to a close by an unanimous vote of thanks to the Court of Directors for their trouble and zeal in managing the affairs of the society.

OXFORD UNIVERSITY AND THE RADCLIFFE INFIRMARY.—The subjoined paper has been circulated :—" It has been suggested that a short printed explanation should be laid before Convocation as to the grant of £500, which the University has been asked to make towards the provision of accommodation for fever cases upon the grounds of the Radcliffe Infirmary. The following statement has in consequence been drawn up by the undersigned, who had the duty of asking the Council to recommend the making of this grant entrusted to them. The governors of the Radcliffe Infirmary, having decided to provide certain accommodation for fever cases, have determined to draw largely upon their own resources in furtherance of this object. They have also sought aid from other sources besides the University, and as they have reason to believe, with good hope of their application being successful. The peculiar interest which the University has in the establishment of such an addition to the Radcliffe Infirmary as the one contemplated has not been overlooked. This will be seen from the following extract from a resolution passed at a special court of the Governors of the Infirmary, held May 12, 1869 :—' That these, or some other beds, be also available for use by patients whose friends are willing to remunerate the infirmary, to the extent at least of the whole course of their treatment, whenever such beds are not likely to be in requisition for the poor.' ' It has been decided to provide upon the present occasion accommodation for sixteen fever cases; and the powers given by a recent resolution to the committee of management as to the application of the capital of the infirmary in aid of the undertaking furnish a sufficient guarantee for the completion of the work.'—John Slatter, Henry W. Acland, George Rolleston."

◆

NOTICES TO CORRESPONDENTS.

IN all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

DR. JONES.—The subject has been fully discussed in our columns.

MR. GASCOYNE.—Thanks. It shall have early attention.

J. D.—The paragraph in question is simply untrue.

DR. MOUDON.—The letter, like several others, is unavoidably postponed.

J. L.—Messrs. Churchill and Sons.

DR. WARING-CURRAN's address has been mislaid. He would oblige by forwarding it.

DR. WUCHERER, Bahia, Brazil.—Your communication upon worms of a species not yet described, met with in the urine of patients suffering from Intertropical Hæmaturia in Brazil has come to hand, and shall receive early attention.

DR. WILLIAMS.—The letter on Legally-qualified Midwives shall appear in our next.

DR. J. WILLIAMS, America.—By next mail, you will receive the [illegible] volumes of this journal, as per your order for which we tender our thanks, also all the copies up to the present time, issued since the amalgamation of the MEDICAL PRESS and the MEDICAL CIRCULAR.

During the past fortnight we have been favoured with several very flattering letters from America and Canada, as to the high position this journal has attained in those countries. Our friends will please accept our best thanks for their congratulatory communications.

COMMUNICATIONS, Enclosures, &c., received from Mr. Summers, Haverfordwest ; Mr. J. Finlayson, Manchester ; Mr. J. G. Wilkinson, London ; Mr. Tichborne, Dublin ; Dr. Palfrey, London ; Dr. W. H. Williams, London ; The Secretary, Anthropological Society ; Mr. T. L. Wilkinson, Owestry ; Mr. Cadbury ; Mr. J. Cope, Manchester ; Mrs. Baines, London ; Messrs. Willmer and Rogers, New York ; Dr. Collenette, Guernsey ; Mr. H. P. Sawyer, New York ; Mr. Grase ; Mr. C. Maw ; Mr. H. E. C. Nourse, Brighton ; Dr. Holman, America square ; Mr. R. Lecture.

ON FIBROUS TUMOURS OF THE UTERUS.

By James Palfrey, M.D., M.R.C.P. (Lond).

Assistant Physician, Accoucheur to, and Lecturer on Diseases of Women at the London Hospital; formerly Obstetric Physician to the Farringdon Lying-in Charity, and to the Metropolitan Free Hospital, and to the Surrey Dispensary, &c., &c.

LECTURE V.—Part I.

Gentlemen,—Resuming to-day the consideration of the treatment of these fibrous tumours of the uterus, I wish, before speaking of the management of the separate forms of the disease, to make a remark or two upon a plan of treatment which for many years has been very much in fashion, and which by the sufferers is frequently regarded with implicit faith and confidence. I refer to the periodical resort of patients suffering from fibroid disease to places possessing waters impregnated with various salts, and these waters, taken internally, combined with the daily use for some hours of tepid hip, or entire baths, have long had the reputation of curing these growths of the uterus. The waters of Kreuznach, a town of Rhenish Prussia, have, above all others, enjoyed the reputation of being efficacious in reducing uterine fibroids. The springs of this place are found to be impregnated with the salts of bromine. I have patients who have for several years travelled to these places, and who have returned to their homes at the close of the season certainly in far better general condition than when they left us; but in no case have I seen a real diminution of the uterine growth from which they suffered, and I have long ago arrived at the conclusion that the improvement that takes place in these patients results from the careful general management to which they are subjected by the physician who, residing on the spot, usually takes charge of, and presides over, every movement of each visitor during the period of her visit to "the Baths." Should any of you be sufficiently interested in this subject to wish to pursue it further, I can refer you to the account published by Dr. Prieger, of Kreuznach, as also to the analysis of the waters of that place given by Dr. Sutro in his work on the "German Mineral Waters" (London, 1851). And now let us make a remark or two upon the few special points of treatment that will demand your attention in the first or subperitonial variety of fibroids. It is not often that patients suffering from this form of disease will require much attention. The principal complaint for which you will be consulted will be the inconvenience arising from the weight of the tumour, and in those cases in which it has attained a large size, and exerts pressure upon neighbouring organs (if the pedicle be long enough to admit of its moving freely about in the abdominal cavity), pain in, or disturbance of, the functions of the organ so interfered with, you will find both these conditions relieved by the use of a silk elastic abdominal belt, so made as to be drawn over the patient's legs and envelop her abdomen and pelvis. I have long discarded the use of those belts, which being fastened behind (in many cases, by almost innumerable laces, buckles, straps, and other contrivances), fail, in consequence of the unequal pressure they exert, to be of the slightest use. A simple elastic belt, slightly stiffened by some thin whalebone slips in front, and an under strap and pad to keep it in position, suffices to give support to the abdominal parietes, and removes the pressure which the growth causes upon the abdominal viscera. Here I must mention a condition you will not unfrequently be called upon to treat. In my first lecture I said that although I had never seen true inflammation of a fibrous body, yet active inflammation of the peritoneum covering these growths was not a rare occurrence, and it is in these cases of sub-peritoneal tumours that this limited peritonitis most often takes place. The attack, as I have seen it, usually begins in much the same way as simple peritonitis, rigors, heat of skin, and a rapid, but not the usually small, hard pulse of peritonitis are conditions soon followed by acute pain of greater or less severity in the region of the growth. This pain is always increased on pressure. The patient lies on her back with the thighs drawn up and flexed; the countenance, however, is never expressive of that intense anxiety and suffering which is so characteristic of puerperal inflammation. The tongue is white and coated, the tip and edges being red; vomiting is generally present, and increases the patient's distress; there is also constipation from the beginning, and often tympanitis. The attack usually runs its course in seven, or eight, or ten days. The treatment I have adopted has not been heroic; usually eight or ten leeches to the painful spot, followed by the constant use of spongio piline, soaked with hot poppy decoction; this followed in a few hours by the hypodermic injection of some quarter or third of a grain of morphia in solution. The internal administration of solid opium in one or two grain doses, every four or six hours, to relieve pain and stay peristaltic action, a cradle over the abdomen to prevent pressure of the bedclothes, the daily use of the warm vaginal douche, and about the sixth or seventh day the exhibition of a warm gruel and turpentine enema, perfect mental and bodily rest, ice in various forms, such as iced milk, orange or lemon water ices, iced beef tea, administered at short intervals in very small quantities, are the means I have seen sufficient to conduct the patient safely through the attack I have described. There is one fact concerning this limited inflammation I must record, and it is that these attacks are very likely to recur. I have seen on three or four separate occasions a most interesting example of this acute inflammation with Mr. Joseph Loane, of Whitechapel; it occurred in a woman the subject of a sub-peritoneal fibroid weighing many pounds. On each occasion the patient has been to all appearances dangerously ill, and in considerable peril, the pain and vomiting on the first occasion inducing very considerable exhaustion. From each attack this patient has wholly recovered, and been able to resume her usual duties. I may observe that I have abstained in the majority of these cases that I have had to treat from giving any form of alcohol during the attack, and the patients have done well without the exhibition of any form of stimulant. I have never yet seen a fatal result follow an attack of this circumscribed and limited peritonitis. I must tell you that these tumours have been removed on various occasions by opening the abdominal cavity, as is done in ovariotomy—the pedicle of the growth being ligatured or divided by the écraseur. The success that has attended the operation has been very small indeed, deaths from hæmorrhage, peritonitis, or pyæmia, following the removal of the tumour in the majority of the cases in which it has been performed. Several times I have been urged by the subjects of these sub-peritoneal growths to undertake their removal in this way, but I have in every instance refused, because I believe the occasions are very rare indeed that this form of the disease destroys, or even shortens life, and seeing that at all times, and under the most favourable circumstances, the abdominal incision is an operation attended with very grave and serious risks, I consider that I am not justified in placing a woman's life in great and severe peril for the advantage of ridding her of a growth which, at the worst, is but an inconvenience and disfigurement. It is but fair to tell you, however, that Dr. Atlee, of Philadelphia, has opened the abdomen, and removed these out-growths on many occasions. You will find a very interesting account of his operations, and the results that have attended them, in a paper he published in the transactions of the American Medical Association for 1853, entitled "The Surgical Treatment of Certain Fibrous Tumours of the Womb." Now and then also it has happened, and that too in the hands of some of our most experienced and accomplished obstetricians, that these sub-peritoneal fibroids have been mistaken for ovarian tumours, and their removal has been effected after the parietes have been divided, and the mistake made apparent. In conclusion upon this first form of Fibroid, I will remark, that should any special symptom present itself, or any accident occur in the progress of the case, you must treat that symptom or accident in exactly the same way you would if it were to occur in the course of disease in any other organ of the body. Bring, I say, your general principles of therapeutics to bear upon the conditions, and you will act wisely. In treating the interstitial form of Fibroids the symptoms that will most frequently demand your attention are:—1st. Congestive tumefaction of the whole uterus, which will manifest itself not only in increased sensibility of that portion of the uterine wall in which the tumour is situated, but by a general tenderness of, and increase in the volume of, the womb, and more especially will this hypertrophy, be noticed just before each menstrual period. No treatment is so successful for the relief of this congestive state as repeated local blood-lettings by means of leeches applied to the os uteri, this proceeding followed by a warm hip bath, and a full dose of the tincture of hyoscyamus, has never in my hands failed to relieve the troublesome and distressing symptoms I have just mentioned, and I know of but one contra-indication to the adoption of the plan above proposed, and that is the presence of profound anæmia. Of course, should this latter condition be present in this, or any other form of the disease, you will pause before abstracting even the smallest quantity of blood. Do your best in this case by a generous diet and the judicious administration (in the intervals of the menstrual periods) of some form of iron, combined with the observance of every hygienic means calculated to improve and restore the healthy character of the blood, and having succeeded in this then you may resort carefully to the local abstraction of blood from the congested uterus. The second important symptom in this variety of fibrous tumour will be pain as I have before told you, sometimes it will be lumbar, at other times it will be hypogastric pain that will call for relief. Now, without doubt, the most speedy manner of relieving these various pains is the administration of opium or some of its salts. My experience has taught me that the patients in every class of life very soon become accustomed to the use of this drug, and before long by the gradual increase in the quantity taken, they tolerate its use to such an extent that the quantities they take is, in many instances, enormous. Hence it is that I ask you to put off as long as possible the habitual administration of this drug, patiently try the various sedatives; give in turn for the relief of these pains—hyoscyamus conium, the extract and tincture of cannabis indica, aconite, and the other remedies of this class, and when at last you are driven, as you will be, to commence the use of opium, begin by using a vaginal pessary composed of one half a grain of sulphate of morphia made into a suitable form with the butter of cacao, and let this be carried to the upper part of the vagina (the patient being at the time in bed) as often as the severity and duration of the pain demands; should this after a time fail to give ease and relief from suffering, I then advise you to commence the administration of morphia by the hypodermic method, a quarter of a grain or even less than this quantity injected in the neighbourhood of the pain is always followed by many hours of freedom from distress. The instrument I have for some years used, is one made for me by Mr. J. Banks, of the firm of Maw and Son. I send it round to you, and you will see that each turn of the screw represents the injection of a drop of the solution of morphia, one grain of the salt being contained in ♏xxiv of the solution.

(To be continued.)

◆

FOREIGN OBJECTS IN THE LUNG.

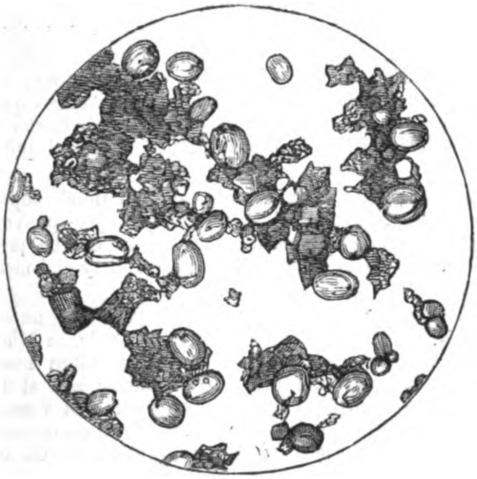
A METALLIC tube composed of zinc and copper, one half an inch long, and weighing eleven grains, was recently in a fit of coughing expelled from the lungs of a girl twelve years of age, living in New York City. The tube, being the whistle of an india-rubber air ball, was two years ago accidentally forced into the upper part of the larynx, and thence in the attempts to remove it by emetics, was lodged in the lungs. During the whole of the period mentioned, the girl suffered from an oppressive senation on the chest and from continued coughing. During one of the paroxysms the tube was ejected. This occurrence gives a strong illustration of the remedial force of nature which is sometimes successful in affording relief when all the resources of surgery and medicine have been tried and failed.

Our Analytical Department.

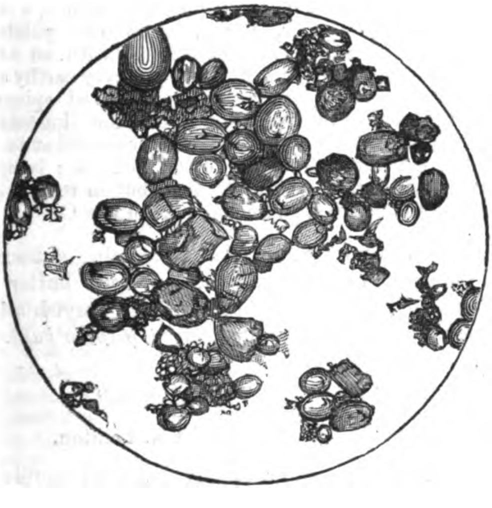
COCOA.

REPORT ON THE QUALITY AT PRESENT SUPPLIED TO THE BRITISH MARKET.

(Continued from page 456



Epps's Cocoa.—This sample was unavoidable left out of our last number.



—Collier's "Patent Cocoa," from a micro-photograph, magnified 200 diam.

20th Sample.—National Cocoa.

Messrs. J. and S. Fry and Sons, London and Bristol.

This sample consisted of almost 40 parts of cocoa, 38 of sugar, and 22 of starch, which seems to have been submitted to heat.—*Largely mixed with starch and sugar.*

21st Sample.—Improved Pearl Cocoa.

Messrs. Taylor Brothers, London.

This sample consisted of about 34 parts of cocoa, 42½ of sugar, and 24½ of starch; contains granules of arrowroot and sago meal. The ash was rather coloured, and amounted to 2 per cent.—*Largely mixed with sugar and starch.*

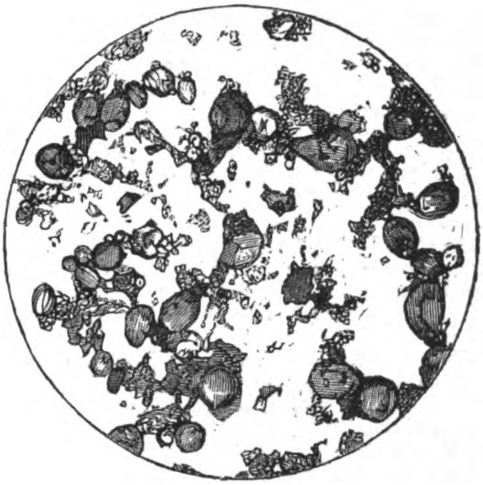


Fig. 6.—Fry's "National Cocoa," 200 diam.

22nd Sample.—Concentrated Meat Cocoa.

Messrs. Dunn and Hewett, London.

Examined microscopically, this preparation was found to consist of muscular fibre, cocoa, arrowroot and sugar. It contained about 50 per cent. of cocoa, and gave 2 per cent. of ash.—*Consists of cocoa, meat, arrowroot, and sugar.*

23rd Sample.—"Improved Homœopathic Cocoa."

Messrs. J. and S. Fry and Sons, London and Bristol.

This sample consists of about 50 of cocoa, 25 of sugar, and 21 of arrowroot, with sago meal. It is very difficult to say, as regards this cocoa, what is the origin of the starch from the fact that it evidently has been submitted to some heating process, by which the granules are burst. The amount of ash was 2 per cent. in this sample.—*Largely mixed with about equal weights of arrowroot and sugar.*

24th Sample.—"Caraccas Cocoa."

Messrs. J. and S. Fry and Sons, London and Bristol.

This specimen consisted of about 54 cocoa, 32 sugar, and 14 arrowroot, which had been submitted to a similar treatment as that in No. 23 Sample:—*Largely mixed with sugar, and small quantity of arrowroot; cocoa good quality.*

25th Sample.—Fry's Iceland Moss Cocoa.

Messrs. J. and S. Fry and Sons, London and Bristol.

From advertisements.

"A preparation of cocoa combined with Iceland moss, adapted for persons of weak digestion, and for general consumption."

Contained about 46 parts of cocoa, 34 of sugar, and 20 of starch. The starchy matter in this sample consists of arrowroot, the granules of which have been burnt by heat, sago meal, and a little Iceland moss.—*Contains a large proportion of sugar, and small quantity of arrowroot, sago meal, and Iceland moss.*

26th Sample.—Chocolat-Menier.

From advertisements.

"Model manufactory, founded in 1825, at Noisiel-on-

Marne, near Paris, for the special manufacture of chocolate of superior quality.

"The Chocolat-Menier is to be found everywhere in town and country; there is no alimentary substance which has acquired a greater or a more merited reputation. Is it not, in fact, the first which, from its low price and its superior quality, has been placed within the reach of all? It offers what the most particular amateurs seek for, and what all medical men desire—a wholesome and agreeable food, and a renovating power.

"Those advantages are due to a special system of manufacture, and to a careful selection of the raw materials, which M. Menier import direct from his own plantations, or through agents residing in the countries where they are best produced.

"The Chocolat-Menier, prepared with the most particular care, recommends itself by its nutritive and digestive properties, as well as by its fine flavour and aroma.

"Its quality, which is unrivalled, defies all honest competition.

"Moreover, M. Menier has found in the report of the International Exhibition of London (1862), a new reward for his efforts in promoting and extending the general consumption of chocolate, After stating that the productions of M. Menier are among the number of those which the jury has particularly remarked, the reporter adds:—

"'The productions of M. Menier come from his large manufactory at Noisiel, where he has at his disposal tools, and a series of apparatus, which enable him to operate on a quantity of the raw material large enough to obtain annually 1,800,000 kilogrammes (four million English pounds) of chocolate. M. Menier, by the extension which he has given to his manufacture, and by the commercial activity he has displayed, has powerfully contributed to extend the use of chocolate.'

"A medal was awarded to him for the 'excellence of quality' of his chocolate.

"Annual consumption now exceeds 5,000,000 lbs.

"The juries of the International Exhibitions of Dublin 1865, and Oporto 1865, have confirmed that decision by awarding new medals to M. Menier for the good quality of his productions."

The sample examined was the quality "fine," in yellow paper; it was pure, and consisted of nothing but sugar and cocoa. The first substance, however, in a very large proportion; it contained about 60 parts of sugar to 40 of cocoa (see sample).—*A pure chocolate; sugar and cocoa.*

27*th Sample.*—Chocolatine.

Messrs. L. A. Loewenthal and Co.

From advertisements.

"The most concentrated, soluble, and invigorating preparation of the purest extract of cocoa obtainable from the most select portion of the choicest cacao or cocoa beans, such as never reach the English market, but are secured by (their) especial agents residing in South America; and by their new process in which no iron or metallic, but only granite, marble, and porcelain, machinery and implements are used, they extract from the most perfect and sound part of the nibs all pernicious, fatty, and other deleterious substances and impurities, rendering chocolatine the most nutritious, alimentary, and delicious beverage ever offered to the public; imparting more vitality and vigour to the digestive organs and the nervous system than any cocoa or chocolate obtainable.

"The most eminent physicians (homœopathic, allopathic, as well as others) recommend this chocolatine especially for its anti-dyspeptic, anti-flatulent, highly tonic, and nerve-soothing properties, pronounce it the best friend of sufferers from indigestion or victims of nervous irritability, strengthening the most delicate digestive organs, and invaluable to invalids and children.

"Chocolatine dissolves almost instantaneously in boiling water or milk, remains unaffected by time or climate, and, by reason of its concentrated form, occupying very little space, is admirably adapted for exportation and sea voyages; in fact, proves far preferable in every respect to the ordinary adulterated cheap cocoas of the day, and quite as economical.

"A few reasons why chocolatine is so much superior, more sanitary, economical, and in every respect preferable, to the common cheap adulterated cocoas of the present day; and why it is daily used by the nobility and medical profession.

"The common cocoa beans (containing the nibs) imported into England, as may be seen, any day of sale, in Mincing lane, are mostly mixed, inferior in quality, often mouldy, unripe, and wormy, and are sold at public sale at 6d. to 1s. 3d. per lb.; whilst the choicest portion of Venezuela and other South American district crops are all contracted for in advance by the few resident agents at 1s. 6d. to 2s. per lb.

"When the first-named cheap cocoas are ground for the preparations now sold, the husks and fibres of the beans (a very unwholesome ligneous substance) are indifferently separated and often remain entirely, and for this reason, as also for the purpose of cheapening the article, a large quantity of sugar, flour, starch, arrowroot, potatoes, damaged sea biscuit, &c., are roasted, and with an addition, in many cases, of Spanish brown (a heavy earthy substance) to give weight and colour, and mixed spices to obscure the taste of these cheap but pernicious ingredient. In this way the cocoa and Co. is sold to the public at 1s. 2d. or 1s. 4d., and wholesale at 8d. to 10d. per lb.; is apparently a very palatable thick beverage, but in reality containing very little cocoa and much more of the Co.

This cocoa is pure, except that it contains a trace of cassia; about 18 to 20 per cent. of the cocoa butter has been removed; gave about 6 per cent. of a greyish ash.—*Genuine; flavoured with cassia, and part of cocoa butter removed.*

28*th Sample.*—"Chocolatine."

Messrs. A. Loewenthal and Co., London.

Wrapped in white paper, exactly similar to sample 27, except that it contained no cassia. This sample and No. 27 were in tin vessels, which did not hold 2¼ ounces, and were marked 9d.—*Genuine.*

29*th Sample.*—Gatti's Chocolate.

The chocolate consisted of about 40 parts cocoa, 50 of sugar, and 10 of starch, mainly consisting of wheat granules.—*Contains starch.*

30*th Sample.*—Fry's Vanilla Chocolate.

Messrs. J. and S. Fry and Sons, London.

A pure chocolate, flavoured, and containing about half cocoa and sugar.—*Genuine; cocoa, sugar, and vanilla.*

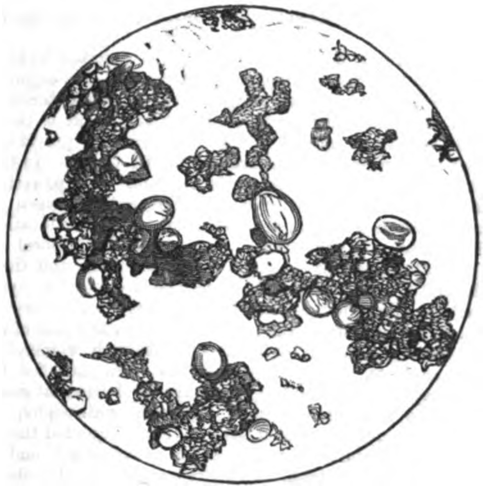

Fig. 7.—"Gatti's Chocolate," 200 diam.

31st Sample.—Chocolat Menier (for eating).
M. Menier, Paris.
Pure; sugar and cocoa (40 *per cent.*).

32nd Sample.—Fry's Chocolate for Eating.
Messrs. J. and S. Fry and Sons, London.
Genuine; sugar and cocoa (42 *per cent.*)

33rd Sample.—Chocolate Creams.
Messrs. Cadbury Brothers, London and Birmingham.
Genuine; cocoa and sugar.

IODIDE OF AMMONIUM IN DISEASES OF THE GLANDULAR SYSTEM.

By I. Waring-Curran, L.K. & Q.C.P.I., L.R.C.S.I., &c.

The iodide of ammonium in diseases of the glands I find by experience a much more active therapeutic agent than that of the iodide of potassium, whether internally administered or locally applied. In the following forms of glandular disease I can testify to its efficacy and curative properties, and have no hesitation in pronouncing it one of the best preparations with which I am acquainted.

Goitre.—There is no part of England wherein I have seen more cases of bronchocele than at Bacup, a cotton manufacturing valley, about twenty miles from Manchester. Sixty per cent. of the female population suffer from goitre in some shape or form. The usual history is, that it commences "*during the pains of the first labour.*" I have had ample opportunity of remarking the accuracy of the statement that there was a connexion between goitre and the uterine functions, that the gland became enlarged during the menstrual period, and particularly so in old goitres in women about change of life, when the discharge is scanty and the colour altered. All the several varieties of bronchocele are to be seen in the valley of Rossendale. One patient is so unfortunate as to possess one which I am confident would weigh fourteen pounds; it extends over the clavicles and sternum, upon which latter it rubs, and causes little inconvenience apparently. The enlargement has been steadily increasing for thirty-seven years.

Cases of incipient goitre treated soon after their being first observed with the iodide of ammonium made good and permanent recoveries. I prescribe the iodide thus:—

℞ Ammonii iodidi, gr. xl.
Spiritus chloroformi, ʒij.
Aquæ camphoræ ad., ℥viij.
Cup. ℥j., ter in die.

At the same time I direct the following cerate to be rubbed into the growth night and morning:—

℞ Ammonii iodidi, ʒij.
Glycerini, ʒij.
Adipecis benzont, ℥jss.

In some few cases I have obtained great benefit by stopping the iodide of ammonium mixture for a few days, and substituting the hypophosphites of lime. Hitherto, I have inwardly given the old standard formula of iodine with iodide of potassium, but a more extensive field in the treatment of the complaint convinces me of the superiority of the drug I advocate.

Tabes mesenterica.—The local application of the iodide of ammonium ointment over the abdomen, and the internal administration of the same drug—the age of the patient guiding the dose to be exhibited—surpass any form of treatment previously had recourse to. Of course the convalescence is slow, and cod-liver oil or glycerine, pancreatine and suet and milk must be given; but these I include more among the articles of diet than the medicines of the physician. A steady perseverance with these measures effects much good. The iodide of ammonium appears to reduce the size of the enlarged glands whose functions are impeded, and to permit the process of assimilation to go on in its natural way.

Strumous enlargement of the lymphatics, wherever situated, if treated before pus has actually formed on the areolar tissue covering the part disorganised, will, as a rule, yield to the iodide of ammonium, combined with a generous diet and change of air. I have before me, in my case-book, the history of a girl, aged eleven years, who had long suffered from strumous enlargement of the cervical glands, the sequelæ of scarlet fever. She had taken syrup of the iodide of iron, Parrish's "chemical food," iodide of potassium, quinine, and cod-liver oil, but without effect. As a last resource, and it was one of the first cases wherein I prescribed it, I directed her to take three-grain doses of the iodide of ammonium twice a day, and to apply the cerate containing the same preparation. I had the satisfaction of observing day after day the well marked gradual diminution of the glands, and the speedy restoration to health. The relatives informed me afterwards that their patience was so exhausted with the girl failing to improve, that they were in the act of calling in further advice. Had such been done, and the iodide of ammonium prescribed, the consequences would have been unpleasant in the extreme. And how often is it that members of our profession obtain a notoriety through similar occurrences, while in one or two instances I know they had not the honesty to give credit where it was actually due and well won, but retained for themselves a success to which they were far from entitled.

Simple strumous adenitis gives way more rapidly and with better results under the iodide of ammonium than any other treatment.

Sympathetic bubo has, in four cases which I have specially treated with the medicine advocated, terminated so satisfactorily that I cannot refrain from recording the circumstance.

Enlargement of spleen after ague.—I had an opportunity last August of testing the therapeutic effect of the ammonium in some cases of enlarged spleen in a most fenny district of South Lincolnshire. Although the benefit was not permanent in any of the cases, as I believe it was not persevered in for a sufficient length of time, yet, during the period the drug was being administered, the more immediate symptoms appeared to yield to it.

Chronic hepatic enlargement has in several instances been recorded in my case-book, where blue pill, podophyllin, taraxicum, and nitro-muriatic acid have proved inert, turned out as cured. I can strongly recommend the drug in this disease, but I invariably blister the hepatic region first, and then dress the blistered surface with the iodide of ammonium cerate.

Tubercular sarcocele was treated in three instances by the iodide of ammonium. In two of the cases there was a syphilitic history, and as the patients were pressing for a speedy rather than an effectual recovery, I combined four drachms of blue ointment with the iodide of ammonium cerate, with the best effects subsequently; so that I am unable to give all the credit to the iodide of ammonium—a drug which my experience teaches only requires to be fairly experimented with in order to be more generally employed in diseases of the glandular system.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

Edited by W. Thornley Stoker, M.D., L.R.C.S.,
Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

The use of opium in the treatment of hare-lip after operation.

Mr. Macnamara's Clinique.

In showing to his class an infant on whom he had performed the operation for the cure of hare-lip, Mr. Macnamara took occasion to speak of the extreme value of opium as a means of quieting the child and assisting the surgeon during the healing of the wound. He was in the habit of using it constantly, and he believed that its employment was one of the great points in the treatment of such cases. Its dose, of course, must be carefully proportionate to the age of the patient, and although he operated as soon as the children were brought to him, thinking that the earlier the fissure was closed the better, he had seen no ill effects following its use. In infants of the age of that which he showed them—eight weeks—the following formula afforded a mixture of sufficient strength :—

℞ Tinct. opii, ♏ij.
Syrupi, fl. dr. ij.
Aquæ, fl. dr. vj. ♏

Of this mixture, a teaspoonful should be given every hour until the child became quieted, and should then be used in sufficient quantity to continue the effect. The use of the opium should, he thought, be continued until the wound was sufficiently united to prevent it being torn by the cries and struggles of the little patient.

Transactions of Societies.

THE ANTHROPOLOGICAL SOCIETY OF LONDON.

At its last meeting this Society entered again on the old question of the relations of the sexes. Two papers were read summarising the two opposite views, a brief abstract of these will be found interesting.

The first paper was read by Mr. G. Harris, F.S.A., on

THE DISTINCTIONS MENTAL AND MORAL, OCCASIONED BY DIFFERENCE IN SEX.

The difference between the sexes was asserted to be one of a material nature only, affecting not merely the organisation, but also the texture and temperament of the material frame, which could not however be supposed to extend to the immaterial part of our nature. A great difference prevails in different departments of nature in regard to sex. In the case of some animals, the female is larger and more powerful than the male; and however great the difference between individuals occasioned by sex, that occasioned by age, education, and other causes, are wider still. Among mankind moral as well as mental differences ought to be considered; and the establishment of a difference did not necessarily imply a superiority on either side, though one sex must necessarily assume the rule. Among animals the greatest feats in the way of instinct have been performed by females. Although women have, in many respects, greater opportunities than men for literary effort, especially in the large amount of leisure at command, they have not equalled men either in philosophy, poetry, painting, or music. But if they have not equalled the men as composers, they have rivalled them as vocalists, and also as performers on the stage. In history and fiction female writers have been below the rank of male authors; in the art of letter-writing they have perhaps in certain respects, exceeded them. As regards certain moral qualities, however, such as courage and constancy, experience might lead us to doubt whether the females might not claim the superiority; in deeds of heroism they have rivalled, if not eclipsed, the men. In respect for their capacity for government, the instances adduced of great female sovereigns, showed that here also the softer sex is fully capacitated for the highest duties. As regards professions fitted for females, those which embraced the care and instruction of the young, and ministering to the sick, women are peculiarly adapted to fill; and in many branches of literature, as well as in business of several kinds, they are fitted to engage. Nevertheless the differences between the sexes are both essential and extensive, and such as no artificial attempts can lessen; that difference, however, may not be one of actual mental or moral superiority on either side; each sex has its proper sphere of exertion and its sphere of duty, in which, and in which alone, it is calculated to excel.

The second paper read was by Mr. J. McGrigor Allan F.A.S.L.

ON THE REAL DIFFERENCES IN THE MINDS OF MEN AND WOMEN,

Which was intended as a challenge to the advocates of the intellectual equality of the sexes. It entered into elaborate arguments in support of the propositions that "There must be radical, permanent distinctions in mental and moral conformation, corresponding with those in the physicial organisation of the sexes." The writer held that man excels in reason—woman in intuition; and adduced as a proof of woman's inferior reflective power, her superior instinct, in which man is surpassed by most mammalia. Girls are quicker than boys, because woman reaches maturity sooner than man,—a strong argument against the alleged equality of the sexes. Woman is always more or less an invalid. For physiological reasons, which underlie the whole question, no woman can pursue uninterrupted mental and physical labour, like man. The paper contained details as to the relative size and conformation of the crania and brains of man and woman. The assertion, that women are successful rivals of men in the fields of intellectual labour was disputed. Women are not first-rate novelists. In the highest branches of art they cannot compete with men. Of all public professions, the stage offers an opening the most legitimate for female energy and talent. Women excel as singers, dancers, actresses, and musical performers. Here there can be no invidious rivalry of sex. All women are more or less actresses, for nature and habit combine to render them proficients. In the highest realms of literature and science, man reigns supreme. The inventing, discovering, creating, cogitative mind is pre-eminently male. In the domain of pure reason, it is extremely doubtful whether women have contributed one profound original idea of permanent value to the world. Women who fulfil conjugal and maternal duties properly, are the finest specimens of the sex, and are working far more efficiently for the mental and moral progress of mankind, than those who complain of the tyranny of man and the slavery of women. We dare not ignore the lessons of experience. Thousands of years have amply demonstrated the mental supremacy of man; and an attempt to revolutionise the *status* of women on the assumption of an imaginary equality, would, as Dr. Broca says, "induce a perturbance in the evolution of races; and hence it follows that the condition of women in society must be carefully studied by the anthropologist." Women who claim equality of the sexes are, in reality, contending for empire. They want masculine in addition to feminine privileges. They wish to be both men and women, but are nondescripts. The study of nature leads us to scout the palpable falsehood, that there are no real distinctions in the minds of men and women.

SURGICAL SOCIETY OF IRELAND.

(Continued from page 459.)

Dr. Kennedy said the person with the fracture of the radius to whom Mr. Tufnell had referred was recently under his care in the Cork Street Fever Hospital with an attack of pneumonia, fromw hich he had recovered. His attention was directed to the deformity of the man's arm, and on asking him about it he said he had been lockjawed for twenty-eight days and recovered under the care of Mr. Tufnell. With regard to the treatment of tetanus, there had been several recoveries after mercury, and he thought therefore that treatment by mercury should not be forgotten. That great physiologist, Lockart Clarke, had established the fact that on *post-mortem* examinations of the spinal chord of persons who had died of tetanus there was something like inflammatory matter poured out.

Dr. Hewitt should be glad to know if any of the members of the society had experience of the hypodermic injection of atropine? He had read recently the statistics of some cases of tetanus treated by that means, and out of eleven cases there were nine recoveries. Of the two who did not recover one was such an advanced case as to be almost hopeless when the hypodermic injection was resorted to.

Professor Macnamara said that some years ago he went through a good deal of labour to ascertain what was the most successful mode of treating tetanus. The result of his investigation up to that time was that by far the greater number of successful cases were due to the administration of belladonna. At the same time, he thought the treatment by nicotine should be fairly tested.

Dr. White said that he saw a case treated by sub-cutaneous injection under the care of Mr. James Stannus Hughes. It was of the subacate form, similar to the case brought forward by Mr. Morgan; for he looked on it as a rule that all cases of acute tetanus die. Dr. Hughes used a solution of atropine, and the man left the hospital quite well. It was a mild case, however, which would have got well without any treatment. If there was any line of treatment to be relied on in tetanus, he thought it was by the use of mercury; and he thought Dr. Morgan's case was no exception to the rule, for the man was mercurialised before the treatment by nicotine was tried. Some years ago he met with two cases of traumatic tetanus, which recovered under mercurial treatment. He learned that from their President's father; he followed that treatment until the patient became convalescent. In each there was some return of the spasms, and he then used the treatment by belladonna. He had seen both those individuals lately, and both were healthy and doing well. If the statistics were looked into narrowly it would be found difficult to discover cases which had been exclusively treated by one method. Whenever a hospital surgeon saw a case of tetanus they ransacked the pharmacœopia to see how much medicine they could put into the patient. He saw no reason for departing from the calomel treatment, and then when spasms remained, trying belladonna.

Dr. E. Hamilton said that Dr. Frazer, the assistant lecturer on Maderia Medica in Glasgow had published the statistics of cases in which the Calabar bean had been used by sub-cutaneous injection; and he stated that there are as many as nine cures out of eleven cases treated by that method. This was well worthy the attention of the surgeon, and it ought to receive a fair trial. It was his intention to put it to the test whenever an opportunity arose for so doing. The solution must be a neutral one. The solution of one-third of a grain in water was acid, but it could be neutralized by carbonate of soda. It might be injected every three or four hours with advantage.

Mr. Croly had seen several cases of tetanus in the City of Dublin Hospital; and the experience of the surgeons there was that acute cases of tetanus were rapidly fatal, and that nothing could save the patient. The first case he saw of recovery by mercury was that alluded to by Mr. Tufnell, where the boy's hand had been injured by a hook. He had had three or four cases under his own care of recovery from tetanus, but none of them were very severe. He had a case of idiopathic tetanus in a person who had been exposed to great heat in a tan yard during the time he was house-surgeon at the City of Dublin Hospital. He chloroformed that case, beginning the chloroform inhalation the moment he saw the yawning occur. The spasm was relieved, but the instant an attempt was made to give fluid, it was regurgitated through the nose. The only effect of chloroform was to quiet the death of the patient. He had seen nicotine used with success. He thought sufficient credit was not given to the late Mr. O'Beirne for having introduced this treatment. He advocated tobacco treatment, which was practically the same as nicotine. It should also be remembered that it was to another Dublin surgeon, Abraham Colles, that they were indebted for the introduction of the mercurial treatment.

Professor Macnamara observed, in reply to an observation of Dr. White, that in the analysis he had made he carefully excluded every case in which other medicines besides belladonna had been relied on; and he ascertained, beyond doubt that when belladonna had been steadily given, more recoveries were due to it than to any other mode of treatment up to the time he made the investigation.

Mr. Stapleton had seen belladonna used by the late Mr. Kirby, and when the patient died, the stomach was found full of green belladonna mixture. He had seen great dilatation of the pupils produced by the use of belladonna, but without the slightest benefit to the patient. He had had one case of tetanus that recovered. The symptoms did not come on until eighteen or nineteen days after the accident. He believed he was the first person that called the attention of the society to a case of tetanus treated by the inhalation of chloroform. He thought at first he had a great success, for when the patient was put under the influence of it he was able to open his mouth, and to drink and swallow his medicine. The spasms continued, chloroform was again administered, and in the end, when the man was fully under the influence of chloform, he had spasms which nearly jerked him out of the bed. He did not believe they had discovered anything of use in acute tetanus, and he did not think the nature of the injury had much to do in aggravating the attack, for he had seen acute tetanus occur from a mere injury of the skin as well as from a compound fracture.

Mr. McDowell said he had seen one case of idiopathic, and two of traumatic tetanus. One of the latter was under the care of Mr. Tufnell, and he thought it was a case of acute tetanus. The effect of nicotine in that case was most remarkable. The man was perfectly rigid. He got a full drop of nicotine, and eight seconds afterwards all his muscles became relaxed, and for fifteen or twenty minutes they remained in a placid state. Gradually the spasms returned again, and on the repetition of the dose subsided.

Mr. B. Wills Richardson remarked that the observations of Professor Macnamara on the subject of the belladonna treatment were of great interest, as they differed so much from the results at which Mr. Curling had arrived. Mr. Curling had shown that, up to the period of the publication of his work on tetanus, there were more recoveries from tetanus after the treatment by tobacco than after the administration of other remedies.

Mr. Morgan in reply said he did not put forward the case as an acute one. No doubt he at first got the man under the influence of mercury, but so far from that being beneficial he got worse under it, and was steadily getting worse until he put him on nicotine. The dose was small at first, but in twenty-four hours amounted to something considerable.

ŒSTRUS VETERINUS FOUND IN THE BRAIN OF THE HORSE.

Dr. J. H. Benson read the following paper:—

Mr. President, I wish to exhibit to the society an interest ing specimen of a *larva* found in the brain of a horse.

Last year my father bought a horse from a gentleman in the country, and got a certificate of the horse's soundness from a veterinary surgeon. On the first occasion, the horse was put in harness after he arrived in Dublin, he went remarkably well, but when, in two days afterwards, he was again driven, he went very awkwardly and heavy, and scarcely obeyed the bit. By the next day it had become almost impossible to drive him, for, besides his heavy slovenly gait, at intervals of about forty or fifty yards, he would make a sudden rush to the right side of the road, totally regardless of the many conveyances that might be passing at the time, and almost quite unrestrained by the rein. With the greatest difficulty, however, and with the most praiseworthy good temper on the part of the coachman, who thought at the time that it was "all sulk" on the horse's part, he was at length got home, and was never afterwards put in harness. He began now to look sick, dropped his head in the stable, refused his oats, hay, and bran, and thinking the whole thing strange, we had Mr. Paley, the veterinary surgeon to see him. Mr. Paley, seemed also puzzled, and was inclined to ascribe his symptoms to the presence of worms in the intestines. Mr. Paley, accordingly purged the horse very freely, but without benefit, for he got weaker and weaker. It now became evident that there was slight paralysis of the left fore-leg, and very soon the horse became incapable of moving in the stable without staggering, and even falling, and subsequently he was altogether unable to stand, though it was plain he preferred that position if it were possible, and he used to make such desperate plunges in his efforts to stand that it was found necessary to pad the walls of the very large box-stall which he occupied, in order to prevent him dashing his brains out. Very large sloughs finally formed on the left hip, shoulder, and side of the forehead; and after a total period of a month's illness he eventually died. As we were anxious to have an accurate and thorough *post-mortem* examination of the different parts, we procured, the valuable assistance of my friend, Dr. McAlister. We first removed the brain and examined carefully its consistence, the ventricles, and the various other parts, and all seemed perfectly normal, until we came to the fourth ventricle. On its floor we perceived some punctiform vascularity, a form rather rare in the brain, and in its cavity we discovered the larva which I have exhibited. It was lying quite free in the cavity of the ventricle without any appearance of a nidus, or any depression in which it might be supposed to have lodged. It was dead. We were unable too, to detect any passage or abnormal communication by which either it or its eggs could have entered. We next took out the heart. It was soft and flabby and very friable, and both Dr. McAlister and I examined it carefully with the microscope, but found no trace of fatty degeneration. The muscular fibres, however, had lost much of their characteristic appearance, and their transverse striæ were very badly marked and almost absent. What I examined first was not a section, nor a fresh cut surface, but a surface which, after it had been cut remained exposed to the atmosphere for twenty-four hours, and had already began slightly to decompose. On examining the scrapings of this surface with a quarter-inch focus lens, I found to my astonishment the whole field of the microscope studded with prismatic crystals of ammonia-magnesian phosphate. I next examined the scrapings of a fresh cut surface but found no crystals whatever; but when that same surface had been exposed for two hours to the air, it exhibited as before the characteristic crystals of triple phosphate. I repeated the experiment several times, and on every occasion with the same result, viz., a fresh cut surface exhibited no crystals, but a surface exposed to the air for an hour and half or upwards, contained innumerable minute crystals; and the longer the surface was exposed the larger and more perfect were the crystals. As to the other parts, the intestines contained a great number of bots, and the spinal cord was somewhat softened in its cervical region. I regret that the horse's urine was not examined. Possibly we might have found sugar in the excretion on account of the irritation of the floor of the fourth ventricle, which, according to Claude Bernard, produces temporary diabetes. However, that same physiologist says, that section of the spinal cord checks the formation of sugar, and in this case the *softening* of the cord might have acted in a similar way. The other organs of the body appeared sound. As to the presence of the crystals of triple phosphate on the cut surface of the heart, I have not been able to hear or read of anything similar having been observed. However, we can very well understand how the thing may have occurred, since we had present all the constituents of the salt, viz., ammonia, as a product of decomposition, and magnesia, phosphoric acid and water, as normal constituents of muscular tissue. But with reference to the most interesting fact, namely, the presence of the larva in the horse's brain, it may seem almost incredible, yet such is the fact, for I saw it there *in situ* myself, before it was disturbed. But its mere presence is not the only strange circumstance about it. It is an external rare species of the genus œstrus and class to which the common bot belongs. For a long while I was unable to find any reference to it, or get any clue as to its nature; but a few hours ago Dr. McAlister, who took an interest in it, kindly informed me that he has ascertained that the larva was described, but not figured, by Bracey Clarke, in the 3rd vol. of Trans. Linnean Society, in the year 1796, and afterwards by the same gentleman in 1841, under the name of *œstrus veterinus*. Clarke mentions the larva as having been found in the stomach and frontal sinus of a horse. Previous to Clarke's description Linnæus described the larva under the name of *œstrus nasalis* having found it in the nose of a horse, but it has never been described by anyone as having been found in the *brain* of any animal, as this was. Nor can we account for its presence in the fourth ventricle? It certainly seems difficult to suppose it could have made its way there from the frontal sinuses, but it would be still more difficult to account for its presence by any other way that I know of. When looking over the new edition of *Kirby and Spence's Entomology*, I met a passage which suggests the probable way by which this animal effected an entrance into the brain. In speaking of a large blue fly, of Jamacia, which "buzzes about the sick in the last stages of fever," the author says—"An instance is recorded of a lady, who, after recovering from a fever, fell a victim to the maggots of this fly, which from the nose found their way through the *os cribriforme* into the cavity of the skull, and afterwards into the brain." Its entrance accordingly by some such way as through the cribriform bone seems to me the only tenable supposition; and once in the brain, we could understand its finding its way to the fourth ventricle.

Mr. Stapleton asked were there any lung symptoms?

Dr. Benson replied that there was some slight difficulty of breathing, but not well marked.

Dr. McAlister remarked that he had assisted Dr. Benson in examining the brain of the horse, and that it was singular to find a larva in a cavity so comparatively closed as the fourth ventricle. He believed the larva to be that of *œstrus nasalis* of Linnæus, the *œstrus veterinus* of Bracey Clarke. He remarked that there were three species of œstrus whose larvæ were parasitic in the horse; œ. equus. or the common bot. œ. hæmorrhadalis *and œ. veterinus*. He also stated that it was an interesting fact that in ancient times these gadflies were probably more numerous in Britain than they are now, for Festus Avinus tells us that Hamilcar Barca, the Carthagenian, in his voyage to the west of Europe, visited the *Insulæ Ostrymuoides*, or Island of Gadflies, by which he meant Britain.

Dr. Kennedy thought the symptoms must be set down to something more than the larva in the vertricle.

Dr. Stapleton said that the sub-arachnoid fluid communicated with the fourth ventricle, and if the larva got into the sub-arachnoid fluid he did not see why it might not get into the ventricle also.

Mr. McAlister said he had mentioned that the fourth ventricle was to all intents and purposes a closed cavity. He knew it had an opening, but he would like to see Dr. Stapleton forcing such a larva as that into it.

Mr. Stapleton.—It was small when it got in, and subsequently grew to its present size.

Mr. Croly observed that in case of death from staggers in a horse it would be worth while ascertaining whether the symptoms might not have arisen from an affection of this fourth ventricle. It was a question whether irritation of the ventricle would produce sugar in the urine, and whether the presence of sugar would produce staggers.

Dr. Benson, in reply to Mr. Morgan, said that the *post-mortem* examination had been made thirty-six hours after death. As to Dr. Kennedy's observations, he did not put forward the existence of this larva in the ventricle as producing the symptoms. He thought if they were not cause and effect they were certainly remarkable coincidences.

THE PRESIDET'S ADDRESS.

Gentlemen,—I shall not detain you with any lengthened remarks at this late hour, but it now becomes my duty to announce that our meeting to night closes this session of the Surgical Society of Ireland, and in doing so, I feel that I can fairly congratulate you on the undiminished success which has attended our meetings. The objects which the Society had in view have been fulfilled in a most satisfactory manner, and I am confident that our proceedings, and the importance of the communications, would contrast favourably with those of any other Medical Society in Great Britain, or on the continent of Europe.

When I had the honour of presiding at the opening meeting of the Session now past, I ventured to predict that the flourishing condition of the Society would continue, and certainly I feel that you will agree with me in stating that our most sanguine expectations have been realized.

In the first place, our meetings have been largely attended, secondly, the discussions which have taken place although at times animated, and even warm, yet they have always borne the stamp of that courtesy and good feeling which should ever mark the cultivators of one of the noblest, most useful, and learned of all the professions; lastly, the communications which have been brought before you are remarkable for their variety and practical value.

I shall now give you a brief analysis of the proceedings of the meetings held during the past Session :—

First Meeting.

Mr. Morgan exhibited an interesting specimen of Syphilitic Disease of the Larynx.

Professor Hargrave read a case of Cancer of the male breast.

Dr. Hewitt exhibited the ulcerated intestines removed from a patient who died of Typhoid Fever.

Mr. Stapleton detailed a case of Medullary Cancer of the left buttock.

Dr. Kinkead communicated a case of Exfoliation of greater portions of both parietal, and the frontal bones after a severe burn.

Mr. Croly read a paper on Femoral Hernia, and advocated not opening the sac.

Second Meeting.

The Vice-President exhibited a specimen and cast of Enchondroma of the second and third finger of the right hand.

Mr. Morgan exhibited a specimen of Syphilitic Disease of the Larynx in a Female. Gangrene of the nose also occurred in this patient.

Mr. Stokes read a paper on Fracture of the Larynx.

Dr. Henry Kennedy read Notes on Medicines.

Third Meeting.

Mr. Croly related a case of Lithotomy.

Mr. Morgan read a case of Subclavian Aneurism.

Mr. Fleming exhibited a drawing of a case of Subcoracoid Dislocation in a patient aged twelve years.

Fourth Meeting.

Mr. Morgan exhibited a specimen of Destruction of the female urethra by Ulceration.

Dr. Frank Thorpe Porter related a case of Intestinal Obstruction.

Dr. Charles Moore read a paper suggesting the use of a tin director under starch bandages, whilst cutting them.

Mr. Morgan communicated a case of Popliteal Aneurism cured by Compression.

Mr. Brookey exhibited a specimen of Ossification of the right Gluteus Maximus muscle.

Dr. W. F. Stoker exhibited a good example of Hour-glass Contraction of the Stomach.

Mr. Edward Hamilton exhibited a specimen of fracture of the fourth Cervical Vertebra.

Fifth Meeting.

Mr. Maurice H. Collis related the histories of cases of Myeloid Tumours of the jaws.

Mr. Stokes read a case of Femoral Hernia successfully treated by operation without opening the sac.

Dr. Darby exhibited an ingenious Splint for fracture of the thigh.

Mr. Richardson exhibited a section of a Hemp-seed Oxalate of Lime Calculus.

Sixth Meeting.

Dr. John H. Benson exhibited a specimen of Medullary Cancer of the liver and kidneys.

Dr. Nolan, of Wicklow, communicated a case of Compound Dislocation of the ankle-joint.

Mr. Croly read cases of Fracture of the Fibula.

Professor Mapother related a case of Simultaneous Dislocation of both Patillæ outwards.

Seventh Meeting.

Mr. Croly read the histories of cases of Operations on the Jaws.

Mr. Stokes read a paper on Wharton's Amputation of the Thigh.

Eighth Meeting.

Mr. Tufnell related a case of Ilio-Femoral Aneurism in which he ligatured the external Iliac artery.

Dr. Hewitt exhibited a good specimen of Ulcer of the Stomach.

Dr. Darby read a paper on the operation for Femoral Hernia without opening the sac.

Mr. Wharton exhibited a useful Splint for extending the Knee-joint.

Gentlemen,—I am sure you will join with me in expressing the opinion that the character and work done, is highly creditable to the gentlemen who took part in our proceedings, and to the Society itself.

The President said I have been congratulating you on our prosperity—I have pointed to the bright side of the picture; but, alas, it has its reverse. This society has sustained a sad and severe loss since I had the honour of presiding at the opening of the session now at its close. Then there was one present who was apparently in the vigour of manhood, full of life and energy, and, as far as we could judge, forward in the race for professional advancement. A true lover of his art, he laboured to elevate Irish surgery. It is needless for me to say that I allude to Maurice Henry Collis. In every way he took a deep interest in this society; he rejoiced in all its successes, he was a most regular attendant at the meetings of its council and its evening re-unions. From his earliest days, as a practising surgeon, he brought forward communications of great value, and was on all occasions wont to take part in the practical discussions with clearness and ability; and whilst he always maintained his own opinion, by sound reasoning and force of argument, he was ever ready to listen to that of others who differed from him with an attentive ear and liberal mind. Gentlemen, I could speak of his high and noble traits of character, of his sincere friendship, during a period of nearly twenty years that we were associated as colleagues; but this is not the place. I wish to do honour to his name and his memory within these walls, that have often echoed to his voice whilst labouring to advance surgery. That voice is now for ever still, but he has left a bright example to the younger members of our profession that they would do well to follow. A Christian man, an educated gentleman, an accomplished and bold surgeon, a sincere and warm-hearted friend has passed away, but his memory will, through years yet to come, be respected, and students not yet born will read in the pages of our professional literature, truthful and practical lessons from his pen. Gentlemen, before we separate allow me to thank you for the courtesy and support you have extended towards me on all occasions since I occupied the presidental chair, and to express the sincere hope that we may all meet again at the commencement of next session in the enjoyment of health and energy to enter upon the work of this society; and that, although the communications during the session just terminated have been numerous and important, the next one may be even more useful to the Surgical Society of Ireland and the profession at large.

The following report was received by the Secretaries, but was not read owing to the pressure of matter :—

REMARKABLE CASE OF RECOVERY FROM VERY EXTENSIVE INJURIES RECEIVED ON BOARD A SHIP IN 1860.

By Dr. John Williams; Macroom, Co. Cork.

"As I have recently received a note of the progress of this interesting case which I saw in Australia, and which was communicated by me to the society shortly after my reaching home from that country in 1862, I am anxious to publish it, as it will complete what the society will join me in considering a case of no little importance. I think it well, however, to recapitulate its leading points.

W.B., a young man, aged 20, left England for Australia, in the merchant ship "Queen of Commerce," in November, 1860. On the third day after setting out, a fierce gale sprung up, which knocked about in confusion all the articles on deck, during which W.B. was thrown prostrate, and a large spar rolled over both his legs, causing the following injuries, viz.,—

1. Dislocation of the right femur into the ischiatic notch.
2. Fracture of the same bone about its centre.
3. Fracture of the lower end of the left leg, with displacement of the left ankle.

As may be expected, he was removed to his berth more dead than alive.

The usual restoratives were given to him, but as there was no medical man on board, the fracture of the thigh, which was the only injury recognised, was very clumsily treated. In the providence of God he got through all, and reached Melbourne in safety. The medical men there endeavoured to reduce the dislocation from the ischiatic notch; but in their attempts to do so the femur again gave way where it had been fractured. They of course desisted from any further attempt, and left matters in *statu quo*. He again recovered. I saw him in November, 1861, having received from home information of the occurrence, and that his mother was anxious I should see him and report to her of his exact state.

When I met him he was walking about Melbourne simply with the aid of a walking-stick. As might have been expected, he was very lame, and complained much to me of his left ankle, which he said troubled him more than anything else. His general health, however, was very good. I found, on measurement, that there was two inches and a half shortening of the right leg."

I lately received the following note of this remarkable case:—"Willie is quite well, and expects from his quartz-crushing machine great results at the gold diggings, where he is at present."

The above case already shows what great results unaided nature can accomplish.

REGISTERED FOR TRANSMISSION ABROAD.

THE MEDICAL PRESS AND CIRCULAR *is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning. Price 5d. Stamped 6d.*

By Post to Annual Subscribers, £1 2 6

„ *If paid in advance,* 1 1 8

* Post-Office Orders and Cheques to be drawn in favour of A. A. TINDALL, 20, King William-street, Strand, London,

WEDNESDAY, JUNE 9, 1869.

BRIGHTON DRAINAGE.

WE have often had occasion to speak somewhat strongly on the sensational character of the articles in some of our leading Medical Journals on subjects connected with the sanitary condition of large towns. And there are few Journals that sin in this respect to habitually, so carelessly, indeed we may add, so wilfully as "the *Lancet.*" It would seem as though it felt that its special duty was to disturb everybody's peace of mind, by assuring them either that they were being poisoned by drinking contaminated water, or else that their health was being slowly but surely ruined by breathing noxious and impure air.

What pleasure there can be in rendering one's neighbour's life a misery, by frightening him at every turn, we on our part, are at a loss to imagine. Men now a days have about enough to cut short their existence with the harassing troubles of the bankbook and the ledger; it is a very hard thing indeed that they should be further annoyed by being assurred that before very long their years will be cut short by the water they are obliged to drink, and the air of heaven that they can't help breathing. And yet this is the story the *Lancet* is perpetually ding-donging into our ears.

We hope the inhabitants of Brighton will neither be ruined or killed outright, by the horrors which the *Lancet* has lately discussed in its usual flightly and sensational manner, for although their recent articles on the main drainage of the town has no doubt created great anxiety in the public mind, yet it is consoling to find that from recent and exhaustive enquiries into the subject, there is really no ground for serious apprehension. That Brighton is at the present time suffering from a sort of desertion of the place by visitors, we will admit, yet it must on reflection be comforting that the same kind of desertion is felt by all the watering places of the kingdom. It can hardly, indeed, be expected that after the serious money panic of 1866, there should be the same amount of money spent in pleasure as formerly; and this in fact is the true cause of that falling off in the trade of Brighton, which has been the subject of remark by the inhabitants. The *Lancet,* however, would have us believe that the condition of the drainage of Brighton is the sole cause of the mischief; for with its usual tendency to prejudge such questions, and to excite alarm by the use of the strongest sensational language, it has lately discussed this question in a manner which is unworthy of any journal that lays claim to a philosophical or medical character.

And now for facts. This matter is of necessity brought before the Town Council. They immediately apply to their own engineer, who is fully competent to report on the whole case, to show the cause, and suggest the remedy. He thoroughly investigates the matter, employs experienced divers to examine the outfall pipes, and the bottom of the sea in the vicinity, he examines the sea and sea-shore at all times and states of the tide, wind and weather. Further he advised calling in a skilled scientific man to make a chemical examination of the water and soil near the sewer outfall. He selected (and could he have made a better choice ?) Dr. Letheby, the Health Officer of the City of London, and one who has been the mover in all the great sanitary works, not merely of London, but of all the large towns in England. Eighty-nine samples of the water and sand are forwarded to him, and it is important to bear in mind, these are taken when the weather was remarkably fine, at the time of low tide, and from such situations as were most likely to contain decomposing matter. The reports of these gentlemen are before us.

Mr. Lockwood reports that the pipe was in thoroughly good order. He tells us he penned up the sewage for some hours, and then let it out at one gush; the water was of course as we should expect, discoloured over the mouth of the pipe, but he adds, "the discoloured water so accumulated, has been removed by the tidal current in a very short time." It is the sewage from this outfall some distance from the town, about which the *Lancet* has made all this fuss. Mr. Lockwood asserts there was no offensive smell from the mouth of the pipe, although the boat for the diver's use was moored over the spot for many days together; and what is more striking, that many people went out in boats from sheer curiosity to see what was going on, but *never made any complaint whatever.* But even allowing this sewage to be a nuisance, Mr. Lockwood points out that the flow is not towards the shore, but eastward and westward. Mr. Lockwood now refers to a remarkable circumstance; blocks of chalk *near the mouth of the pipe* were brought to the surface, and they were clean, white, and inoffensive, and bored through in every direction with pholades, many of which were living at the time of the examination. Further, "whelks, sea-hogs," star-fish, &c.,

were also found clinging to the outside of the pipe, and to the piles near the end of it, and sprats have been observed in great numbers near the mouth of the pipe." We all know how sensitive animal life is to any of these matters; for it cannot exist in sewage water, and this of itself is an unmistakeable argument against the theories so carelessly advanced. Mr. Lockwood adds, "As far as my own examinations have at present gone, I have not been able to trace any offensive smell whatever, arising on the beach or the sea frontage to the outfall proper, which is in good repair, and appears to work well."

We turn now to Dr. Letheby's report of his examination of the water and sand. He examined forty-nine samples of sand. *Six* of them smelt strongly, but more of decomposing seaweed than sewage. *Fifteen* had a slight smell of the same nature. *Twenty-eight* had no smell at all. And on comparing the amount of organic matter in the sand, with other specimens of mud that he has examined, Dr. Letheby gives the following table :—

Average per centage amount of organic matter in the following substances in a dry state.

	Organic matter per cent.
28 Samples of Brighton Sand (inodorous) . .	1·58
15 ditto ditto (slightly odorous) .	2·14
6 ditto ditto (still more so) . .	5·29
Mud at Main Drainage Outfall, London . .	15·00
Muddy matters in Thames Water, at London Brg.	21·37
Mud from St. Catherine's Dock, London . .	30·17
ditto East India Dock, London . .	19·67
ditto Streets (stone pavements) London.	47·19
Matters deposited from average London Sewage.	49·83

With respect to the water, Dr. Letheby states, that of forty samples, three only were offensive, and these were taken from the sewer and the storm water outlet; but the water taken about *fifty yards* in each direction from it was perfectly inodorous, and only contained a little in excess of the normal quantity of ammonia. At 100 yards it was impossible to discover in any way a trace of the sewage, and Dr. Letheby adds :—"It is manifest from these results that the dilution of the sewage from the main outfall is so rapid, and so large, that it quickly ceases to be discoverable."

Both Dr. Letheby and Mr. Lockwood remark that the refuse of fishmonger's and putrid bait are allowed to be thrown on the seashore. They recommended that steps should be taken to prevent this disagreeable practice, and Dr. Letheby thinks that any disagreeable odours noticed on the beach is probably referable to this. Certainly, all the evidence goes to prove that the sewer arrangement is most efficient, and to use Dr. Letheby's own words, "There are no real grounds for apprehension as regards its being a nuisance, or even in the remotest degree dangerous to public health."

After these reports we beg most emphatically to protest against an unwarrantable article in the "*Lancet*" of the 29th of last month, in which they assert that the ruin of the town is inevitable, because the Town Council will not attend to the trashy nonsense they have written on the subject. And next, we beg to protest against almost libellous assertions as to Dr. Letheby's disqualification for undertaking this examination, for no other reason than that he will not lend himself to the absurd and sensational views expressed by the *Lancet*. It is time, and we would put this candidly and firmly before the *Lancet* authorities, to stop professional humbug, but having coolly and carefully made a full examination of the facts, then to judge a righteous judgment.

THE BRITISH MEDICAL ASSOCIATION AND ITS JOURNAL.

The protest to which we gave expression some weeks since, in reference to the extravagant and resultless expenditure of the funds of the British Medical Association has been vigorously reechoed by the *Medical Mirror*, which journal quotes, for the purpose of refuting, the reply offered by the Editor of the *British Medical Journal*, to the animadversions of our contemporaries. In truth, the Editor of the *British Medical Journal* makes no defence to our assertion, that the paper and ink of the Association absorbs the whole of its vitality. His answer is that the *British Medical Journal* is not overfed by an outlay of £6,000 a year; for, says he, "the members of the medical profession are able by an annual subscription of a guinea, to *provide for themselves so powerful an organisation for scientific, social, and political purposes*, as the British Medical Association." "A powerful organisation for scientific, social, and political purposes" truly!—Where? Does the British Medical Association exist at all for any scientific, social, or political purpose? What is the gain to the profession from the subscription of members of the Association?

The Editor says :—

> "At no period has it been occupied more briskly or usefully in the public relations of medicine or in advancing its scientific interests, nor has it ever identified itself more thoroughly with the popular interests of the profession. At the same time, it has won the warm adhesion of all the most eminent and illustrious medical authorities. The value and necessity of a weekly medium of communication is, we have reason to believe, felt every week more completely; *and all experience has proved that, in proportion to the increased efficiency of the* Journal, *the prosperity, numbers, and usefulness of the Association increase.*"

We unhesitatingly declare that there is not a single public relation of medicine" or movement for "the advancement of its scientific" or "popular interest" which the Association has occupied itself about, nor has it even made a show of identifying itself with the wants of the profession, of which, Heaven knows, there is no lack.

The very title of the Association has come to be nothing more than a draw—a trick to persuade subscribers that they are something greater and more respectable than the outside barbarians who buy their newspaper from a mercenary publisher. The *Medical Mirror* justly says :—

> "The subscription list to the *Journal* may be a success; the advertising connection may be also a most successful affair; but that is no reason why nearly every copper of the receipts should be swallowed up by the working expenses of the *Journal*. The same profit which a private proprietor of a similar property would expect from so flourishing a subscription list, and from so large an advertising connection, ought to be earned for the benefit of the community of medical men forming the Association. The editor of the *Journal*, as a shrewd business man, must know that shareholders require a profit from their enterprise, and that whether shareholders pay one guinea, or £500 for a share in an undertaking, the directors of such undertaking are equally responsible to the shareholders for the working of such undertaking, and for a dividend, or for a reason why a dividend is not declared."

The moment has come for the Council of the Association to emerge from the cold shade of their printer; or, if that be not possible, for the members to put their money to better usury than the *Journal* affords them.

Is not the progress of the profession tardy for want of a united and active organisation, and while such a necessity exists will the members continue to do duty simply as the touts of a journal which takes their bread and gives them a stone ?

TESTS OF THE PROFICIENCY OF STUDENTS.

At a recent meeting of the Convocation of the London University, Dr. Edwin Hearne, of Southampton, moved the following resolution, which was carried on a division :—

> "That it be referred to the Annual Committee to consider whether it would be conducive to the interests of the University to abolish the existing regulations respecting admission to the examinations for medical degrees to the students of certain specified schools."

The adoption of this resolution is, we believe, the first official proclamation of the substitution of the examination test for all other certificates of medical education, and it is deserving of the most anxious consideration from medical teachers and licensing bodies.

It has been openly declared in the Medical Council that attendance on lectures is a useless and oppressive requirement from the student, and that the candidate for licence to practise should be called upon to give no other guarantee of his proficiency than the answering of a reformed examination. This is practically the principle which has been affirmed by Dr. Hearne's resolution, and we believe it to be one most dangerous to the status of the profession, and destructive to the high standard of education which ought to be maintained.

That certificates of attendance on lectures and hospitals are at present admittedly a farce and a fraud appears to us to afford not the least argument in favour of the substitution of the examination system. It would be quite as reasonable that the Chancellor of the Exchequer should check smuggling by abolishing taxation altogether; and we are convinced that the depreciation of the profession which would accrue from the adoption of the examination test, *et preteræ nil*, would be infinitely worse than any which can result from the prevalent laxity in the granting of certificates.

The *Medical Mirror* enters at length into an advocacy of Dr. Hearne's resolution, and is betrayed by its ardour not only into an evolution of italics, but into many inconsistent and incorrect statements. Our contemporary says :—

> "The making examinations what they ought to be, being the only test of a sufficient education, is the requisite guarantee, and will effectually secure all that can be reasonably desired, in whatever aspect viewed, whether in the interest of the teacher, the student, the graduate, or the public."

A rather cool assumption, truly! for if it be decided that examination is "the only test of a sufficient education," what need is there for further argument? And if it be obvious that it will "effectually secure all that can be reasonably desired," why should there be an instant's hesitation in sweeping away all restrictions in medical teaching ?

We venture to put to these assertions an unequivocal negative, for we believe that any examination which it be possible to devise must fail to afford a certainty of proficiency in an art in the practice of which so little depends on rule, and so much on judgment and practical skill. We need go no further than the *Medical Mirror* for a very forcible refutation of its own *dictum* :—

> "The present is really a forcing, hot-house system ; but the education of the senses, delicacy in manipulation, manual dexterity, sight, hearing, &c., rebels against it. Their full development must be extended over a considerable period ; for knowledge so acquired cannot be pumped in at will by the energy of a teacher, however intelligent, but is attained by purely personal effort, consequently is too frequently wanting.
>
> "Again, the recognition of the peculiarities of expression, the corrugated brow in a class of head diseases, the retracted upper lip in abdominal, the dilated nostril in thoracic (especially marked in childhood), the peculiarities of colour, and of odour, in other diseases, greatly aid in their diagnosis, and the knowledge founded thereon can only be the result of personal observation, for which large hospitals, and the ordinary rushing through the wards, ever so regularly, for one or two years, provide very inadequate opportunities to become intimately acquainted with such indications, because diseases are not there seen in all their stages, nor is the time now devoted to practical subjects sufficiently prolonged."

An admirable summary of all the advantages of personal, practical, manipulative study; but what form of examination can guarantee it? and if students do not attend hospitals and dissecting-rooms, which they are now obliged to pay for, how will Dr. Hearne ensure their personal experience in the treatment of disease, when they will not be obliged to pay for the opportunity of acquiring it? It is exactly because no examination, fenced with every precaution which it is possible to devise, and conducted by examiners more disinterested and incorruptible than angels, can of itself be a guarantee that the answers have not been made up in a "grind room," that it has been necessary to require evidence of something more than assiduous "coaching." Time has shown that a smart student may pass *any* examination almost without opening a book, soiling his fingers with a subject, or observing a case of disease; and to perpetuate the examination test *alone* would be to accept in their worst form all the abuses which have given rise to the well-deserved unpopularity of the certificate system.

SCOTLAND.

ROYAL SOCIETY OF EDINBURGH.

The concluding meeting of this Society for the present session was held on the 31st ult. Professor Christison, president, in the chair. Mr. Buchan communicated a paper by Mr. Keith Johnston, jun., "On the annual range of temperature over the globe." Professor Tait read a paper "On the polarisation of electrodes under various circumstances," which was followed by a communication by Mr. Joseph John Murphy, "On the causes of volcanic action," which he stated were the elevations of the earth's crust giving local relief from pressure on the lower strata, and enabling the solids and vapours in the deep strata to expand from the heat they contained. Dr. T. R. Fraser read a paper "On the antagonism between the actions of physostigma (Calabar bean) and belladonna." The author described a number of experiments which appear to demonstrate that the fatal action of certain doses of physostigma may be prevented by the administration of belladonna, or its active principle atropia ; and, conversely, that the fatal action of certain doses of belladonna may be prevented by the administration of physostigma. He adopted the following plan in the investigation :— After the minimum fatal dose of each substance had been approximately determined, a fatal dose of the one was administered along with a certain dose of the other, and, if death did not result, the same animal was subsequently killed by a dose of one of these substances equal to, or less than that given in the combination. An experiment was described, in which an animal recovered after receiving a non-fatal dose of atropia combined with a dose of physostigma twice as large as one that was afterwards found sufficient to kill it. Dr. Fraser thought these results would probably place at our disposal a physiological antidote for belladomma poisoning, as well as one for physostigma poisoning. The latter might at any time be practically applied at West Africa, where physostigma (or Calabar bean) is extensively used as an ordeal poison. The President remarked that Dr. Fraser was the first to clearly solve the question whether antagonistic poisons existed, or whether one poison could actually destroy the action of the other; and the experiments of which an account had been given were the only commencement of what would turn out to be a very important scientific discovery. The concluding paper was "On the thermal energy of molecular vortices," read by Professor W. J. Macquorn Rankine of Glasgow.

◆

Notes on Current Topics.

The International Medical Congress at Florence.

L'Imparziale announces that the number of medical practitioners, Italian and foreign, who have already sent in their promises of support to the committee of the International Medical Congress is considerable. *L'Imparziale* invites the medical men of Italy to prove their hospitality and their fraternal feeling, and to make provision for the advent of the strangers who will attend the congress, not only for their hospitable reception, but for a display of scientific work which may leave on their minds a favourable impression of the development and activity of medical science in Italy.

The Mortality at Brussels.

The epidemic of modified typhus which raged in Brussels about three months ago has completely disappeared, and the authorities are about to enter on an elaborate investigation of its causes, and the precautions which should be adopted against a future outbreak.

As our readers will recollect, the disease was a mucous fever, slightly different from typhus, but with very irregular phenomena. Generally this fever was characterised by great depression, by headache, anorexia, and thirst; by a tongue white or punctuated with little red spots; by constipation or diarrhœa, slight heat of skin, slight reaction of the pulse, sleepiness, agitation, and epistaxis.

The symptoms of this fever were not very alarming, but in a few cases it degenerated into typhoid and proved fatal. The civil and military hospitals were crowded, and the aristocratic quarters of the city were invaded by it as well as the poorer districts.

The statistics show that in all there were 3,644 cases, out of which there were 509 deaths, or about 14 per cent. of the seizures, and about one-fifth per cent. of the entire population.

Female Medical Education in London.

The condition of female medical education in London is detailed in the report of the Female Medical Society, which was presented at the general meeting last week. During the last session there had been 12 entries of new students, and two more of the senior students had passed the preliminary examination in arts at Apothecaries' Hall. The total number of ladies who had entered as students during the five years was 81, of whom 43 were single, 22 married, and 16 widowed. Some of those ladies had attended the lectures merely as a means of intellectual culture. Several were relatives of clergymen, 17 were relatives of medical men, 10 were midwives previously in practice), two were hospital matrons, three were superior nurses, one an artist, four were wives, widows, or daughters of chemists, and one was prepared to act as medical missionary to India, in connection with the Society for the Propagation of the Gospel, while a considerable number were or would have been governesses, and some had been previously of no occupation. Some of the earlier students had settled in practice, and were succeeding admirably—one of them occupied a responsible position in connection with the Birmingham Lying-in Hospital, and another, who held a responsible appointment in London, received a salary of £100 for a small portion of her time.

The Late Refusal to Vaccinate.

The conviction of a medical man for refusing to have his child vaccinated, scarcely seems to us to deserve the attention it has received. There are always a number of obstinate people abroad as well as of persons who cannot see the force of a syllogism. It need not then astonish us that some cannot or will not see what seems so clear to the majority. Again, to be in a minority of one, and to suffer a fine of a pound or two for the glorious privilege of declining to obey a law made in the interest of the public, is not an expensive mode of obtaining notoriety. Some writers have considered the case as parallel with scruples in religious matters, and talked as though the recalcitrant were a martyr for conscience sake. It may be worth while to remind them of the entire want of analogy in the two cases. If we were to admit that the alleged risks of some accident or contamination through vaccination were not without foundation, it by no means follows that the State ought not to impose such risk on the individual for the benefit of the masses. It might, indeed, be fairly argued that a moderate proportion of injurious effects, such as those feared, should not weigh with the legislature against the enormous benefits conferred by Jenner's great discovery. Look into the faces of the crowds that daily throng the streets of all our great cities! How few are those disfigured by the frightful small-pox! Let memory recal the picture of forty years ago, and pondering on that contrast would alone suffice to convert ordinary people to the generally accepted view. Then thousands of living, thriving Englishmen, who would have been now in their graves, had not the small-pox plague been stayed by vaccination, are not likely to return to the old practice. They will say, even admitting all alleged against vaccination, better a thousandfold to enforce it than prepare the way for a ravaging pestilence. The safety of the people is involved, and crotchets must give way. *Salus populi suprema lex.*

Epidemic of Cholera in Gambia.

By letters from Gambia dated the 17th ult., it appears that Bathurst has been visited by a very virulent form of this disease. The epidemic first appeared on the 5th ult., on which day seven persons died of cholera. On the 9th there were seventeen more deaths; on the 14th, twenty-nine; on the 15th, thirty-two. The population is only 4,000, so that the epidemic is very severe. On the 17th, 190 persons in all had perished. Cholera was previously unknown to the natives, and they were so alarmed that they could not be induced to assist in burying the victims until Admiral Patey and his Secretary, Mr. Fowler, had set them an example by working themselves at the sad office. Great efforts were being made to improve the sanitary condition of the place. No Europeans had been attacked, but the disease was rapidly extending amongst the other towns on the river.

The Sea as a Motive Power.

A SHREWD engineer of New York thinks he has solved a problem we have often pondered over, viz., how to utilize the waves of the sea. He suggests building on the beach a dyke several hundred feet long, admitting the waves, but not letting them recede. This is done by having in the sea face of the dike openings of conduits which conduct the water to a reservoir within the dyke. A canal from the reservoir, reconducts the water by a circuitous route to the ocean, to turn, on its way, the wheels of as many mills as can be built on the canal banks.

University of Oxford.

IN a Convocation held on the 3rd instant it was agreed that a sum of £1,000 be placed at the disposal of the Professor of Experimental Philosophy, for the purpose of providing apparatus to be set up in the physical laboratories now building at the University Museum.

IT was also agreed that a sum of money not exceeding £350 be granted to the Waynfleet Professor of Chymistry for one year, to be expended as follows :—For a demonstrator in the laboratory, £100 ; for assistants at lectures, apparatus, and chymicals, £250.—total, £350. Also that the sum of £100 be granted to the curators of the University galleries, on account, towards the expense of mounting the valuable collections of engravings given to the University by Mr. Francis Douce and Mr. Chambers Hall.

It was likewise agreed that the sum of £200 be granted from the University chest towards defraying the expenses of the exploration of Sinai.

The name of Edward Chapman, M.A., of Merton College, who has been nominated to the office of Examiner in the Room of Gilbert Child, M.D., Exeter College, "*in scientiâ naturali* "*pro hâc vice*, was submitted to the House and approved.

Education of the Deaf and Dumb.

THE results of the examination of the pupils of the Jews' Deaf and Dumb Home at Tulse Hill, in audible speaking and lip-reading has led to an important resolution originated by Mr. H. A. Isaacs, viz., the preparation of a scheme for the establishment of a day school, which shall, upon the payment of certain fees to be determined by the committee in regard to the pecuniary resources of the parents or guardians of the applicants," be open to deaf mutes of all religious denominations ?

Royal College of Surgeons of England.

INFORMATION has been forwarded to us to the effect that the supporters of Mr. Edwin Hearne have, through an oversight, omitted to fulfil the needful formalities as to the nomination until too late, so that provincial fellows will be deprived of the opportunity of supporting one of their body this year. We are, however, assured that next year a vigorous effort will be made to carry Mr. Hearne.

Under these circumstances provincial fellows will be glad to learn that Mr. Henry Lee is very much alive to their interests. Possibly, unfortunately for himself, Mr. Lee is strongly opposed to canvassing. But when we remember how his colleague at St. George's, Mr. Prescott Hewitt, was carried into the council in spite of such an objection to canvassing, and how glad we were to aid him, in consequence of the position he therein assumed, we cannot refrain from expressing our hope that Mr. Henry Lee will not suffer for the honourable and dignified attitude he takes.

Vaccination in Bombay.

THE following is a letter to Government from the Bombay Association, regarding vaccination in the town and island of Bombay :—

To the Chief Secretary to Government, General Department, Bombay.

SIR,—I have been instructed by the managing committee of the Bombay Association to acknowledge the receipt of the Resolution recorded by His Excellency the Right Hon'ble the Governor in Council, on the subject of vaccination, accompanied with a copy of the report from the Superintendent-General of Vaccination, Bombay Presidency, requesting the Bombay Association to communicate their opinion to Government as to the advisability of rendering vaccination compulsory in the town and island of Bombay.

In reply, I have been directed to state, for the information of Government, that the managing committee have given their most careful consideration to this important subject, and that they are of opinion that it is not advisable to render vaccination compulsory in the city of Bombay, because an interference with the liberty of the subject is calculated to excite opposition, and produce dissatisfaction and discontent amongst the people, and the advantages expected to result from the proposal in question, are not commensurate with the evils which it may engender.

The committee are further of opinion that the object of Government in regard to the increase of vaccination can be better attained by persuasion than by force. The committee think that by providing a sufficient quantity of the vaccine lymph, by employing an increased number of vaccinators, and instructing them to go to the houses of the people to vaccinate their children, and by requesting the vaccinators and the Graduates of the Grant Medical College to give the most extensive publicity amongst all classes of the community to the advantages resulting from vaccination, the objections and prejudices of the lower classes may be successfully overcome, and the necessity of having recourse to legislation avoided.—I have the honour to be, sir, your most obedient servant,

(Sd.) NOWROZJEE FURDOONJEE, Secretary,
Bombay Association Office, Sassoon Building,
Elphinstone Circle, 24th April, 1869.

Infanticide.

DR. LANKESTER delivered a lecture on "Infanticide" last Thursday night in the Freemason's Hall, at which Mr. C. Reed, M.P., presided. Infanticide he defined to be the destruction or murder of a new-born child, but under another name the law also took cognisance of the destruction of a child before it was born. He proposed to deal with the former of these crimes. In 1863 there were 55 cases of infanticide in his district; in 1864, 56 ; in 1865, 61 ; in 1866, 75 ; in 1867, 53 ; and in 1868, 52;

but in too many instances he discovered a tendency to return open verdicts of "found dead" or "still-born." According to the judicial statistics of the Home Office, the rate of the crime for England was 1 in 170,000 of the population, and in Middlesex 1 in 20,000; while for the central and western districts it was 1 in 12,000, confirming him in the opinion that the crime was mainly confined to the domestics of the West-end. Indeed, on an average of five years, the return for Clerkenwell was 1 in 30,000; St. Pancras, 1 in 20,000; Marylebone, 1 in 10,000; Paddington, 1 in 8,000; and in Islington, 1 in 6,000. Having shown that the mother was generally alone in the murder and disposal of her child, Dr. Lankester went on to assert that the verdicts afforded no indication of the actual number of cases. He believed Mr. Wakley was right in fixing it at 300 a year; and as the murderess was generally twenty years of age, and seldom repeated her crime, taking the average life of women at sixty, it followed that there were 12,000 women living who had committed the offence. He next glanced at the deaths occasioned amongst mothers, and the effects of "baby farming," observing that half the children upon whom he held inquests were illegitimate, and that from 40 to 80 per cent. of children admitted into foundling hospitals die within the first year; and concluded by stating his cure for the evil, which was to be worked through the pulpit, an alteration of the bastardy law, as not more than 1 in 70 of the fathers contributes to the support of the child, the substitution of other than capital punishment for the crime, a certified registration of births, as in Ireland and Scotland, and of still-borns as on the Continent.—*Globe.*

The Health of Dublin.

In the Dublin Registration District the births registered during the week ending May 29th, amounted to 186. The average number in the corresponding week of the years 1864 to '68 inclusive, was 172. The deaths registered during the week were 149. The average number in the corresponding week of the previous five years was 137. Only two deaths from fever were registered, both being from fever of the typhoid or enteric type: the average number of deaths from fever during the corresponding week of the previous five years was ten. Five deaths resulted from scarlatina, being only half the number registered during the previous week. Six deaths were referred to diarrhœa. Phthisis or pulmonary consumption caused twenty-five deaths, and hydrocephalus, or water on the brain, four. Apoplexy resulted in three deaths, and paralysis in a like number. Six children died from convulsions. Seven deaths were caused by heart disease, and one by aneurism. Bronchitis was fatal in twenty instances, and pneumonia or inflammation of the lungs, in five. One death was caused by nephria or Bright's disease. Five accidental deaths and one case of suicide were registered.

The Order of the Bath.

The following promotions and appointments are announced in the *London Gazette* of the 1st instant:—"To be Ordinary Members of the Military division of the Second Class, or Knight Commanders of the said Most Honourable Order: Thomas Galbraith Logan, Esq., M.D., C.B., Director-General of the Medical Department of the Army. To be ordinary members of the Military Division of the Third Class, or Companions of the said Most Hon. Order: Inspector-General of Hospitals and Fleets George Burn, M.D.; Inspector-General of Hospitals George Steward Beatson, M.D.; Deputy Inspector-General of Hospitals Hampden Hugh Massy, M.D.; Staff Surgeon-Major George Saunders. To be ordinary member of the Civil Division of the Third Class, or Companion of the said Most Hon. Order: John Grant Stewart, Esq., M.D., Inspector-General of Hospitals and Fleets."

The Loyalty of the Medical Club.

On Wednesday last there was a "house dinner" at the Medical Club, and being the day appointed for the celebration of the Queen's birthday, it was the occasion of the usual loyal toast being drunk with unusual enthusiasm. Mr. Erasmus Wilson, who took the chair this month, and presided with that genial flow of soul for which he is so well known, proposed her Majesty's health in champagne bumpers, which were rapidly despatched by the thirsty doctors and their visitors. "Success to the Medical Club," too, was drunk with "all the honours," as were some other toasts. The speeches were more interesting than might have been expected, the chairman brimming over with genuine humour, having started in a key which was followed by Mr. Hepworth Dixon and Mr. Norman Lockyer, distinguished visitors of such evidently clubable natures that we should be glad to see them proposed as members. Nor must we forget the few words spoken by Dr. Tonson Evanson, the medical poet, whose works had gone before him, and made him a centre of peculiar interest. Meetings like this are evidently calculated to promote harmony amongst medical men, and we could wish that the members severally would exert themselves more to introduce a larger proportion of lay members. It should not be forgotten that scientific and literary men are all eligible for membership, and there are many who would like to join it were they made aware of what it offers. We have supported the club from its commencement. We beg to congratulate Dr. Lory Marsh on having brought his conception into such practical working order that the club is now able to provide for as many guests as the room will hold, a dinner with which every one expressed unalloyed satisfaction; in fact, has enabled the medical men to give full expression to their loyalty by keeping the Queen's birthday in the fashionable manner. Increasing success to the Medical Club!

Miss Garrett has passed the second examination for M.D., at the University of Paris.

The decision in the Court of Queen's Bench, respecting the Coronorship for Middlesex, was given last week agaidst Dr. Hardwicke. Some lawyers tell us that litigation might still be prolonged.

The new nomenclature was distributed by post to London practitioners, by order of the Registrar-General, last Friday, and will probably be received by every medical man by the end of this week.

The University of Cambridge will be open next October to non-collegiate students, *i.e.*, to students who, on the ground of expense or for other reasons, do not wish to become members of colleges. The regulations for such students will be published shortly. The university is, and has for some years, been open to persons of all religious denominations.

THE *Union Medicale* announces that the Swedish Faculty of Medicine is about to open its doors to female doctors, and to issue diplomas equivalent as regards the practice of the profession to those given to men.

M. DUMAS, Perpetual Secretary of the French Academy, will lecture in honour of Faraday, at the invitation of the Chemical Society, on the 17th inst. The Royal Institution have kindly lent for the occasion the room so long used by Faraday.

THE Maharajah of Jeypore has been suffering much lately from cataract of the right eye, and Dr. Macnamara, of Calcutta, who was called to attend his Highness, has recommended change of air at some hill station of the Himalayas. The Maharajah has accordingly applied for, and obtained, permission to visit Simla. So far as can be judged, his Highness will probably be some two months absent from his dominions.

A DISEASE called *pachima* is reported to be fast destroying the cattle of the Soonderbuns, in India. It has appeared in an epidemic form, and its victims invariably fall off and die in the course of two or three days. This epidemic is said not to differ much from the epizootic, or cattle disease of 1864. It is called by the natives *pachima*, or *puschima*, probably because they suppose it to come from the west. Mr. Rainey, in bringing the matter to the notice of the Agricultural and Horticultural Society of India, at a recent meeting in Calcutta, suggested that the Government should cause a simple manual in Bengalee, on the subject of cattle diseases, to be prepared for distribution among the people. Such a work would be of the greatest utility.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE Council have to report, that during the year ending the 5th April, 1869, 4 candidates were admitted to the Fellowship of the College, and 109 Gentlemen received Letters Testimonial; 4 Licentiates obtained the Diploma in Midwifery; 35 Candidates for the Junior Class Examination for Letters Testimonial were rejected; and 20 Candidates for the Final Examination were rejected; 160 Candidates presented themselves for the Preliminary Examination; of these, 12 received First-class Certificates; 37 received Second-class Certificates; 86 received Pass Certificates only; and 25 were rejected.

The entire number now on the lists of the College amounts to 381 Fellows, and 1,944 Licentiates.

Recommendations from the College to the Council.

At a meeting of Council, held on May 28th,—

The recommendations of the Fellows of the College to the Council on the 25th of May, 1868, were read, viz.:—

Proposed by Mr. Darby, seconded by Dr. Tyrrell, and

RESOLVED—"That this meeting recommend to the serious consideration of the Council—1st. That the expenses generally are greater than the resources of the College can prudently afford; therefore it is expedient that a reduction of the expenses should be effected in the following particulars, viz., by reducing servants' wages, &c.; by withholding the remuneration to Members of Council, not an original charge.

"2ndly. The propriety of enabling Fellows to vote by proxy, and the wisdom of applying for a new Charter."

"That the Fellows of the College, whilst acknowledging the attention paid by the Council to their recommendations on a previous occasion, relative to the removal of the portrait of the late Dr. Kingsley to a more appropriate position in the College, would still urge on the Council their former request of placing his portrait in the Board-room, as a compliment justly due to his services and the profession; and it is particularly desirable that it should be done without delay, in consequence of the opinion of Mr. Catterson Smith, that the portrait, if retained in its present position, will suffer injury."

Proposed New Charter.

The Council held a special meeting on July 23rd, to take into consideration the recommendations of the College to them, and to consider the propriety of seeking for a new Charter;

When it was resolved—

"That the question of servants' wages, &c., be referred to the Finance Committee, with a strong recommendation from this Council that the strictest economy, commensurate with efficiency, be enforced in all the departments of the College."

At the same meeting it was unanimously resolved—

"That this Council having carefully taken into consideration, as requested to do by the Fellows at large at the Annual Meeting of the College, held on the 25th May last the propriety of seeking for a new Charter, is of opinion that at present it would be inexpedient so to do."

At the same meeting, it was further unanimously resolved—

"That it having been already decided by the Council that it is inexpedient to apply for a new Charter at present, the propriety of Fellows voting by proxy at the election of Councillors (the mode of voting being already provided for by clause 12 of the Supplemental Charter), cannot be considered."

Remuneration to Councillors for Attendance at Examinations.

At a meeting of Council, held on July 23rd, 1868, it was resolved—

"That it is inadvisable to withhold the remuneration from Members of Council for their attendances at Examinations."

At a meeting of Council, held October 8th, it was resolved—

"That Members of Council shall receive no remuneration for attendance upon Examinations, unless they are present for the full hour of the Examination, or are represented by another member of Council."

Superannuation allowance to Dispensary and Union Medical Officers.

At a meeting of Council, held on June 9th, 1868, it was resolved—

"That the President or Vice-President and Secretary of Council be requested to proceed to London to night, to confer with the Government and members of both Houses of Parliament, on the justice of granting superannuation allowances to Dispensary and Union Medical Officers."

At a meeting of Council, held June 11th, 1868—

The Vice-President reported the result of the deputation to London respecting the Superannuation of Dispensary and Poor Law Medical Officers, who may, by accident, age, or disease, be disabled from attending to their professional duties.

At a meeting of Council, held on June 25th—

Letters were read from the County and City of Cork Medical Protective Association, and the South Eastern Medical Association of Ireland, respecting the necessity of sending a deputation to London, to confer with the Government and Members of both Houses of Parliament, on the justice of granting superannuation allowances to Dispensary and Union Medical Officers.

At a meeting of Council, held on July 2nd, read the following communication, viz.:—

IRISH MEDICAL ASSOCIATION.

Royal College of Surgeons,
(Copy) 30th day of June, 1868.

At the Annual Meeting of the Irish Medical Association held at the Royal College of Surgeons on the first day of June, 1868, it was unanimously resolved—

"That the warm thanks of this meeting, are justly due, and hereby tendered, to the President, Vice-President, Council, and Fellows of the Royal College of Surgeons of Ireland, for the kind and valuable support always afforded by them to the Irish Medical Association, and more particularly for the deputation and strong memorial sent by them to the Legislature, praying for a redress of the unjust grievances at present affecting the Workhouse and Dispensary Medical Officers of Ireland."

Signed,
THOS. L. MACKESY, President.
E. J. QUINAN, Hon. Sec.

At a meeting of Council, held on July 10th, 1868, it was resolved—

"That a Committee be appointed, consisting of the following members, to draw up a Draft Bill for the Superannuation of Poor Law Medical Officers, and that they be empowered to obtain legal assistance, and to act with Doctor Quinan, the Honorary Secretary, and the Council of the Irish Medical Association:—The President, Vice-President, Dr. Hargrave, Dr. Albert Walsh, T. L. Mackesy."

Further resolved at the meeting—

"That the Committee be also empowered to act with the King's and Queen's College of Physicians, should they appoint a Councillor for that object."

Further resolved—

"That Lord Cairnes be requested to present to the House of Lords the petition for the Superannuation Allowance to the Medical Officers of the Poor Law Medical Charities, and that Sir Arthur E. Guinness and Mr. Pim be requested to present it to the House of Commons, and to support the prayer of the petition."

Further resolved—

"That our Solicitor, Mr. Litton be requested to prepare a short Act of Parliament, to provide Superannuation for Medical Officers employed under the Poor Law and Medical Charities' Acts.

At a meeting of Council, held on February 18th, 1869, the following resolution of the Irish Medical Association was read viz.:—

Irish Medical Association.
Royal College of Surgeons,
12th day of February, 1869,

Resolved—That the thanks of the Council of the Irish Medical Association are due, and are hereby tendered to the President, Vice-President, and Council of the Royal College of Surgeons in Ireland, for their valuable assistance in preparing a Superannuation Bill for the Poor Law and Dispensary Medical Officers, and that a deputation do wait upon the President of the Royal College of Surgeons, for the purpose of ascertaining what progress has been made in the Bill, and by what means, if any, the Council of this Association can promote the measure.

Extracted from the minutes of the meeting of the Council of the Irish Medical Association.

E. J. Quinan Hon. Sec.

General Medical Council.

At a meeting of Council, held on December 17th, 1868, it was unanimously resolved—

"That Dr. Hargrave be re-elected as representative to the General Medical Council from this College for the term of five years."

Carmichael Prize Essays.

At a meeting of Council, held on 20th May, it was resolved—

"That counsel's opinion be obtained as to the legality of a member of the Council of the Royal College of Surgeons of Ireland being a candidate for one of the Carmichael Prize Essays, according to the terms of Mr. Carmichael's will."

The following quære having been placed by the Solicitor of the College before Mr. Lawson, Q.C., in compliance with the foregoing resolution, viz.:—

'Whether Dr. Mapother's position, as a member of the Council of the Royal College of Surgeons in Ireland, deprives him of the right to compete, and disentitles him to the prize awarded.'

Mr. Lawson gave the following opinion, viz.:—

"I do not think that Dr. Mapother was deprived of his right to compete, being a member of Council."

The late Dr. Maurice H. Collis.

At a meeting of Council held on April 1st, it was unanimously resolved—

"That this Council has heard with deep regret of the death of Mr. Maurice H. Collis, formerly a member of this Council, and more lately an Examiner of the College. That a copy of the above resolution be forwarded to Mrs. Collis, with the assurance that every member of this Council sympathises most sincerely with her in her present bereavement and affliction."

The late Dr. Mackesy.

At a meeting of Council, held on April 15th, the following resolution was unanimously passed, viz.:—

"That this Council have heard with feelings of sincere regret of the death of their late valued colleague, Dr. Thomas L. Mackesy, and they desire to convey this their feeling to his bereaved and sorrowing family."

Correspondence.

OVER-POPULATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—One or two gentlemen, in the columns of the Medical Press and Circular, have lately questioned the assertion made by all political economists of note, that population has a tendency to double itself in from twenty to thirty years, when abundantly supplied with the means of sustenance. This doubting, however, nearly took place in the years between 1790 and 1810, in the United States of America, independently of immigration.* It is this power of rapid increase which causes our overcrowding and poverty. To explain this more fully, will you favour me by inserting the following?

Yours,
Charles R. Drysdale, M.D.,
99 Southampton row, London, May 28th, 1869.

At a meeting of the London Dialectical Society on Wednesday, a paper was read by Dr. Charles R. Drysdale, "On the Inadequacy of Emigration as a remedy for European Overcrowding and Destitution."

After alluding to the facts that poverty produced most of the evils of human life, such as excessive mortality from consumption, a disease far more prevalent among the poor, than among the rich, and from typhus fever, &c., besides want of happiness of all kinds, Dr. Drysdale said the reason why he contended that emigration, whether assisted by Government, or voluntary, was quite inadequate to remove pauperism, or to raise wages, was because population had a tendency to increase so rapidly as to neutralize all such remedies. He quoted from the works of the Rev. Dr. Chalmers, who perhaps, had of all writers most thoroughly exposed the fallacies of emigration, as a remedy for destitution, from James and J. S. Mill, from Whately, Merivale, Joseph Garnier, Huxley, Darwin, and a number of the most distinguished scientific names, that population, when adequately supplied with food, had been able in several occasions to double itself by procreation alone, in periods from fifteen up to twenty-five years. Hence there was, as the illustrious Mr. Malthus had pointed out in his immortal work, the most important work perhaps, which had ever appeared, in its consequences towards the happiness of the race, a constant tendency for population to exceed the means of subsistence. If this assertion were granted, and the writer believed that it was admitted by all able thinkers, who had examined the evidence for it, although hosts of persons objected to take that trouble, and hence remained in deplorable ignorance, it seemed incontestable, that Europe in general need not look to emigration to take off its possible increase. France had long abandoned all hopes of ameliorating its condition, by exporting its population, and small families were, in that country, looked upon as the only remedy for pauperism by the best French writers on social science as, *e.g.*, Joseph Garnier, &c. Emigration, it was true, had raised wages in Ireland, but an immense amount of suffering had been required to induce the Irish to leave their native soil; and it was to be hoped that such misery might be prevented, and not only attempted to be cured in future, by abstaining from such rapid reproduction. The average number of births to a marriage in this country at present was stated from four to five; in France was little more than three. In fact, the population of France might be said to be stationary, and as a consequence of this, wages were rising and pauperism disappearing in that country. He believed, indeed, that emigration, (and in this belief he was only quoting the opinions of the Rev. Dr. Chalmers) had a tendency to *increase* pauperism by flattering the hopes of the poor and uneducated classes by the promise of a ready provision for any number of children they might choose to engender. With Sismondi, then, he maintained that, wherever mischievous prejudices were not inculculated, in the name of religion, although such teaching could lay no claim to such a sacred name, no parents would bring into the world more children than they could bring up well and provide for at their death. Finally, in the words of the "greatest thinker of the age," Mr. John Stuart Mill, he held that "little improvement can be expected in morality, until the producing of large families is looked upon in the same light as drunkenness, or any other physical excess," since those large families caused, in this already over peopled state, poverty, and its attendant evils, prostitution, infantile mortality, infanticide and the misery and degradation of the race. Of course, emigration was often useful to those who emigrated, but it did not help those who remained behind in the over-peopled countries of Europe. Prostitution, and most of the evils of human life would disappear, if but a prudent conduct like that of the French peasantry, who, according to M. Maurice Block, habitually limit their families to two children, were to come into vogue throughout European States. Marriage, too, might then be universal, and the great end of all true morality, namely, happiness, attained by the immense majority of mankind. It had been objected to the assertion that over-population was the cause of poverty, by Doubleday, Herbert Spencer, and others, that poverty was the cause of rapid breeding. But, the families of the aristocracy from the Queen downwards were usually large, and the French peasantry who had only two children limited their numbers of their own accord, not from any miraculous so-called law of nature like that assumed to exist by Mr. Doubleday and his followers. Dr. Drysdale remarked in conclusion, that many severe strictures had been made upon the utterances of Lord Amberley, himself, and others of the Dialectical Society, in the *Medical Times and Gazette*, by a writer, he believed Dr. Druitt, and also by the *Lancet* and the *British Medical Journal.* He believed that his able *confreres* of the medical profession in general had paid but little attention to the subject of political economy, and did not wonder at this, seeing that the range of medical questions was already so extensive. He only did feel suprised that able men who belonged to one department of science, should speak so slightingly of the discoveries of men like Malthus, Ricardo, Mill, Senior, J. S. Mill, McCulloch, Chalmers, Say, &c. He hoped such superficial criticisms would soon cease, and that his respected brethren would take the trouble calmly to address themselves to the study of the works of these great men; without doing so, they were quite unfit to speak upon topics of public hygiene, or morality in his humble opinion.

---

* See Article on "Population" in Encyclopædia Brit. Edition, 1840.

In the debate which followed,

Mr. **Greening** said that sparseness of population did not cause prosperity, and poverty was, in his opinion, caused by faulty social arrangements. It had been proved that, if wealth were well distributed in this country, each family would have on an average £100 a year. The great error in our social arrangements was the want of co-operation. No less than three and half per cent of the cost of groceries was saved by co-operation, and if the like saving were attained in production, there would be enough for all.

Mr. **Levy** said Mr. Greening could not have spoken to an audience who better appreciated the advantage of co-operation. Poverty, however, was a question of production, rather than of destitution, and production depended on capital, labour, and material objects, and in an over-crowded condition of society like this, it was always a difficult matter to procure enough food for all. If our population were smaller in proportion to our capital we should be better off. It was said that in Russia, where population was sparse, poverty was common; but then in Russia capital was scarce too. Wealth depended upon the proportion between the capital and population of a state. Better distribution of wealth, as spoken of by Mr. Greening, would only do good by checking population, if it raised the standard of comfort of the labourers. Emigration was quite inadequate to compete with the principle of population. For example, the increase of the Chinese, if that nation were to emigrate, would soon fill the world. The Japanese, indeed, found it advisable to prevent Chinese immigration into their territory. What was needed was a less rapid production of families. Emigration was no remedy for low wages.

Mr. **Pratt** observed that, if population were too dense, emigration seemed a good remedy, and one greatly needed, since one million and a quarter of persons were at present dependent on charity, and any other way of checking population was too slow in its operation to alleviate the present distress.

Mr. **Edward Jenkins** said we have plenty of room to double, nay to quadruple our present population, if the land question was but attacked. At present the land of England was held by some 5,000 families. Pauperism was caused by this faulty tenure of land. One half of our labouring population, too, could neither read nor write. Then, too, alcohol and tobacco cost £100,000,000 to the people annually. No people in Europe drank so much, or had such poor education as our poor agricultural labourers. The accumulation of money in the hands of a few increased the evil. There was only one remedy, and that lay in the instruction of the people. He objected to any advice as to the arrest of the healthy blossoming of our population; if any advice were offered it should rather be the postponement of marriage, not the production of small families.

Dr. **Roberts** said that, supposing it were granted that emigration was a cure for poverty, the difficulty was that America and Australia lay at a great distance, and it was said that even in America there was much poverty in the Eastern States. In New York it was said there was immense distress. Where, too, was the capital to come from, for State assisted emigration from this country. It could not be raised either by Government or by the parishes. Mr. Greening had asserted that co-operation would save so much capital as to cause poverty to cease; but it only raised one and a half per cent. in wholesale trades. Hence co-operation was likely to do only an infinitesimally small amount of good in causing pauperism to cease. In order to allow of an accession of population in a country, wealth must precede births. And hitherto, as sure as wealth increased, so did population immediately follow it, and eat up the advantages. Our wealth had recently increased enormously; but, then, so had our population. Hence our present pauperism. If three or four millions of our population were suddenly removed, with the present habits of our labouring population, did anyone imagine that the remainder would not immediately begin to increase far more rapidly than now? Population, unless checked by the voluntary prudence of the masses, could always proceed far more rapidly than it could be drafted off by emigration. Hence emigration was no remedy for poverty.

Mr. **Reed** said that the question of wages was one of production, not of distribution. If we desired then, to raise wages, we must make the number of the population less in proportion to the capital of the country. This was the only real and certain way of improving the condition of the labouring classes. The co-operation principle, though admirable, would only alter the distribution, not the production, of wealth. The population question was the real solution of the difficulty. With regard to the rapid "blossoming" of the population so much admired by Mr. Jenkins and others, it had only resulted in wide spread misery and destitution, and the French peasants, who were found such fault with for their prudent and praiseworthy habits of having but two children, did not exhibit the frightful destitution brought on us by the results of the pretended good advice of our public teachers.

Mr. **McGrigor Allen** said there were three arguments against emigration. 1. Immigration into a country often caused the death and destruction of the natives. Knox said that the Saxon had cleared Tasmania. 2. Then emigration did not get rid of paupers or lunatics, and people died of poverty at home. Then again (3), we were not fitted to live in all parts of the globe. Even in America the physique of the English had degenerated, and it was absurd to think that we could colonize India, since the third generation of Europeans did not exist in India. John Bull should stay at home a little more, and let charity begin at home. Emigration was fraught with evils, and the population law of Malthus was the only solution of the question. Large families, which were the grand cause of poverty and destitution were much to be deprecated.

The meeting then adjourned.

◆

LEGALLY-QUALIFIED MIDWIVES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Since the Royal College of Surgeons of England have determined in future that candidates for the membership shall be examined in midwifery, I suppose henceforward there will be no occasion or rather applicants, for the diploma of L.M. Does it not seem feasible that properly-educated and trained ladies might be examined at the Royal College of Surgeons, and after being found competent, receive the diploma of Licentiate in Midwifery, and so become legally qualified to practise midwifery (strictly practical midwifery only) in any part of the British Empire; thus providing employment for reduced gentlewomen more remunerative and independent than that of a governess, &c? Women are quite as capable of learning the science and art of midwifery as the medical student, if properly taught, and I propose giving them a training four times as severe as that which the student of midwifery receives at the present time, which consists of nothing more or less than a three months' course of lectures upon midwifery and the diseases of women and children, and before going in for examination he must present a certificate to the effect that he has attended twenty cases of midwifery. Surely if a young surgeon is legally recognised as competent to practise midwifery after such a training, a woman should be too, after a more lengthened course of obstetric study, providing she has satisfied her examiners as to her capabilities.

The great objection women have to being attended by one of their own sex in labour is this, they fancy, should anything amiss occur, the midwife "would not have nerve enough." Such a thought is very natural, but when we look at hospital nurses and behold "their nerve" on trying occasions, I think one is safe in concluding that a thoroughly-educated midwife would not be found wanting in any case, however great the emergency might be. Remember they have been theoretically taught the science of midwifery, and, we suppose, would have no difficulty in diagnosing a case of mal-presentation or placenta prævia. Under such circumstances, they would do all science teaches them; at the same time, the friends would be informed of the nature and gravity of the case, and it remains for them to call in the surgeon if they like and the same line of conduct would be applied to puerperal convulsions if desired The educated midwife is not expected to,—nay, will not *wait* for the surgeon to come and tell her what to do; she is to do as she has been taught in such cases, and the surgeon's attendance should be requested only as confirmation of the midwife's opinion, or, to use other words, "just for satisfaction." A duly-qualified midwife would be a great boon to women in the humble class of society; and the general practitioner ought to be very thankful to find he could get rid of a large amount of midwifery without injury to his other practice.

When a woman is confined the midwife's attendance should be dispensed with beyond visiting the patient a time or two afterwards, of course she may prescribe a dose of castor oil, or a few drops of laudanum, or a saline draught as the case might require, but should puerperal fever or peritonitis set in, or mammary abscess follow or any other dangerous symptoms arise then the surgeon's attendance becomes absolutely necessary; and it should be illegal for a midwife to take further charge of the case in a medical point of view: of course there would be no objection to her remaining as head nurse working under the surgeon's order if found convenient. For my part I think the general practitioner ought not to attend much midwifery. If he has a heavy number of obstetric cases to look after and be in readiness for, how can he attend to much general practice at the same time? Not only must his rest at night be broken, and his meals irregular, but all his other practice must be secondary to the midwifery; in fact he is physically a perfect slave, to say nothing of mental anxiety. In large towns the case is not so bad as in the country, for in the former you can leave your patient for a short time to visit some one else, whereas in the latter when a mile or miles away from other patients you must wait many hours, sometimes a whole day or night, in the meantime all your other engagements are on one side, in plain words the rest of your practice goes to the wall. For instance, one has promised to see a patient who is dangerously ill early next morning, a midwifery case comes on in the night lasting for some hours, there is no help for it, you cannot keep your word, and your poor patient must wait until Dame Nature sets you at liberty, you cannot well go away, however clear your judgment of the case may be as regards the time of termination of labour; for women will not be left and it does not do to offend, so all one has to do is to wait patiently. If in course of time it should become fashionable for ladies to attend midwifery, in most cases wherever you found a surgeon in general practice there you would find a lady accoucheur as well, and if it were only publicly known that women were found after strict examination qualified to practise midwifery, I think many ladies would employ them, especially when supported by a surgeon, the ordinary medical attendant, perhaps of the lady to whom the midwife could look for immediate aid if required.

I make no doubt that the majority of my professional brethren will disagree with me *in toto* on this subject, and think that they would all be ruined should it become the rule to employ female obstetricians and not the exception. Let us hope that such would not be the case, and it could not be, providing midwives were restricted from practising general medicine and dealing in drugs, both of which would be impossible (if the Medical Act were only what it ought to be), as a midwife would not come under the head of a registered medical man or chemist. Pure physicians and surgeon-accoucheurs would find a falling-off in their obstetric cases, though there will always be certain ladies who must have one of the sterner sex to attend them; yet, suppose the obstetric physician would not attend above twenty cases in after years where now he attends a hundred, he still has uterine diseases to make a special study of, which will be remunerative, and then there would be his consultations in complicated cases to make up for the loss.

The following course of study seems to me sufficient for the education of a lady accoucheur:—

In the first place, the candidate would be required to pass a preliminary examination in general education, comprising the following subjects—

1st. Reading aloud a passage from an English author.
2nd. Writing from dictation.
3rd. English grammar.
4th. Writing a short English composition, as the description of a place, &c.
5th. Arithmetic to fractions, inclusive.
6th. Outlines of geography.
7th. Outlines of English history.
8th. Rudiments of the Latin language.

Secondly, the candidate must have attended the practice of a lying-in hospital or the obstetric wards of some general hospital or workhouse infirmary for the period of twelve months, such period to be divided into two summer sessions and one winter; at the same time, the following course of lectures must be attended—the summer course consisting of fifty lectures, the winter of one hundred; class examinations to be held weekly.

Each session to consist of two lectures.

Lectures to comprise the following subjects:

FIRST SUMMER.

Lecture I.—On the Osteology and Anatomy of the Pelvis and Parts concerned in Parturition.
Lecture II.—On the Outlines of Midwifery, especially with regard to the Mechanism of Labour.

WINTER SESSION.

Lecture I.—On the Principles and Practice of Midwifery.
Lecture II.—On the Anatomy and Physiology of the several Organs of Generation, with Practical Demonstration by Dissections.

SECOND SUMMER SESSION.

Lecture I.—On Medicine, Therapeutics, and Hygiene, as relating to the Lying-in Woman.
Lecture II.—On Midwifery, more especially as regards Obstetric Operations.

All lectures must be well illustrated by diagrams and preparations, and each candidate must have applied the forceps, gone through the *modus operandi* for removing retained placenta on the leather subject used by the lecturer for his illustrations of practical midwifery.

Furthermore, a candidate must present a certificate of having attended, *per se*, five cases of midwifery within hospital wards and fifteen out. We will now suppose a lady has obtained her diploma of L.M., the question then suggests itself, by what term shall she be known by when speaking of her in society? I think "Accoucheuse" by itself is sufficient —perhaps the prefix of "Surgeon" would render it more striking, and give it greater weight with the public. We have surgeon-dentists emanating from Lincoln's-inn Fields, why not a "Surgeon-Accoucheuse?" After the above course of study, I hope I am right in presuming that a woman should be equal to practise midwifery, and thought deserving of public confidence in the obstetric art.

I am, Sir, yours, &c.,
HENRY W. WILLIAMS, C.M., M.D., L.R.C.P. Ed.
London, June, 1869.

◆

LAW *v.* MEDICINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Having been for many years a subscriber to your valuable paper, I shall feel much obliged if you will kindly insert the following in your next publication: I on the 21st instant, sued, in the County Court of Haverfordwest, a man for a bill for medical attendance. I sent him my bill three years ago, and on this bill authority to pay the amount to a druggist in Haverfordwest of the name of Williams, who transacted business for me. I asked Williams for the money and he said the man had not paid him, so, after waiting till this month I sued him. When in court, the defendant produced my bill, with the authority to pay Williams, receipted by a man named Thomas who lived in the same house that Williams had formerly occupied, who was not authorised by me to receive it. The judge then asked me if the authority produced to pay Williams was in my hand-writing, I replied it was. He then gave judgment against me, saying the man was illiterate and knew no better, and ordered me to pay the costs. I was plaintiff in another case in the same court, and, on the same day, I sued a man for 13s. 6d., 10s. for journey, and 3s. 6d. for medicine. I was sent for, in the middle of a cold wet night, a distance of between three or four miles, to attend the defendant's wife—I sent in my bill as above, I made two or three applications for it and he promised to pay, but not doing so, I sued him. The judge (Terrell), on giving judgment in the matter said, my charge was excessive, and reduced my bill for attendance and medicine to 5s., and ordered me to pay costs, leaving me, thereby, a balance for 2s. for medicine and journey. During the hearing of the case Judge Terrell said he should make no difference between day and night services of medical men, and should award the same allowances in both cases. On hearing the judge's decision, I remarked I hoped every one would be paid at the same ratio, when he ordered me to be taken out of court in custody of a bailiff, for contempt of court. I was kept in a room for half-an-hour till the business of the court was over, and should have been committed to prison for seven days had I not acquiesced, at the solicitations of many friends, to make an apology for objectionable remarks (if any) made, I was then released from the officers of justice. The above statements are quite correct. You will much oblige by letting me know if there is a remedy, and if so, the one applicable, and can I not bring an action for false imprisonment, my not being aware of having in any way, made a remark that could come uder the head of contempt of court.

Yours truly,
R. Summers, M.R.C.S.

Haroldstone, Haverfordwest.
May 24th, 1869.

[We have no hesitation in saying that our correspondent has been most harshly dealt with, and that the decision of the magistrate was utterly illegal. The first defendant was requested to pay Williams and no one else, and if he did pay a wrong person the law recognises no incapacity of education as an excuse.—Ed. Med. Press.]

◆

"COCOA."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In an article on "Cocoa" in your valuable paper, you say last Wednesday, with regard to Van Houten's Cocoa.

"We cannot endorse Dr. Hassall's remarks, however, as regards the comparative cheapness of this cocoa."

This implies, as it stands, a denial of a fact, proved by experience, and in justice to Dr. Hassall, to the manufacturer, and also to the public, I must ask you to qualify this statement of yours, as to its real value, or to show satisfactorily that it is well founded.

I am, Sir,
Yours faithfully,
H. Eschwege, Importer, &c.

6 and 7 Coleman street, London, E.C.
June 5th, 1869.

*** We have not seen Dr. Hassall's original report, and, there-fore, suppose that in Van Houten's advertisement we have it unabridged.

The passage complained of refers to the following paragraphs in Dr. Hassall's report: "I have tested chemically, microscopically, and dietetically Van Houten's Cocoa, and *contrasted it with the best description of Cocoa and Chocolate to be found in the English market*, while the great majority of them consists of mixture of cocoa, starch, &c., Van Houten's is not only composed solely of the cocoa bean, but is of the finest quality.

"Although nominally dearer than many of the English preparations from its greater purity and strength, it goes much further, so that in the end it is really much cheaper."

The two paragraphs taken together would convey an impression that Van Houten's Cocoa is one, if not, the cheapest in the market. Such might have been the case at the time of Dr. Hassall's report—of this we know nothing. Our report is "upon the quality at present supplied to the British market," and, therefore, we cannot endorse this opinion, unless Van Houten's cocoa is *alone* compared with the lower class mixtures which are sold under the name of cocoa. This, however, was not our reading of the advertisement, there are large numbers of pure and good cocoas in the market (which number is increasing every day.) It is with them that we would compare Van Houten's preparation as regards its comparative cheapness.

If we *confined* our consideration of cocoas to one class or those which are mixtures of starch, sugar, and cocoa, Van Houten's *is* comparatively cheaper than such preparations.

◆

MR. STAPLETON'S METHOD FOR FRACTURES OF THE FEMUR NOT NOVEL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—Thirteen years ago I devised this method and have continued to make use of it, and modifications of it, in the practice of the Queen's County Infirmary, where there is, for the purpose, a movable arrangement to attach to any bed, supplying a pulley over which may be suspended a sufficient weight, and the arrangement reduces the treatment of fractures of the femur to that of the most simple. It possesses many advantages as well as comforts to the patient. I have such a case at present in his fourth week, and it has scarcely called for any attention since the first adjustment. I often use only four splints round the thigh, and none other, when the patient may sit up or recline as wished, the only precaution being to have the splints held by an attendant during the change of position. I apply long broad adhesive straps from above the knee down the leg at both sides (supported at intervals by broad circular straps) united below the foot, but kept apart by a bit of wood notched at the ends, this prevents undue pressure on the ankle, thence a cord passing over the puley suspends a weight, usually four pounds. Special cases require Liston's, or other splints, but I doubt the usefulness of too much fixture of the extremely.

The arrangement has all the advantages pointed out by Mr. Stapleton, as also several others, chiefly its allowing of the sitting posture, and the relief it affords to the ankle.

I have gone further and used gentle circular traction in a similar way on the stumps, in certain cases of amputation of the thigh, by circular operation, the results being satisfactory. However, very great care is obviously necessary in such cases as this.

Finally, I may mention that my method has been brought out as novel in America, by Dr. Dugas, of Georgia, and may be found illustrated in Dr. Wales's work, on "Surgical Apparatus Appliances," Philadelphia, 1867.

Very faithfully,
David Jacob M.D.

Maryborough.

Obituary.

JOHN NOLAN, Esq., M.D.

Died, May 28th, at Athboy, county Meath, John Nolan, Esq., M.D., æt. sixty-three. Dr. Nolan graduated at Edinburgh, as a physician, in 1826, became a Member of the College of Surgeons, England, and Licentiate of the Dublin Lying-in Hospital in the following year. He then assisted Dr. Macartney as Demonstrator of Anatomy at the University (Trinity College) School of Physic and Surgery, and wrote the appendix to the "Dublin Dissector."

On the retirement of Dr. Macartney from the College School, Dr. Nolan was elected Physician to the Athboy and Ballioor Dispensaries. There, for a period of thirty years, he laboured through epidemics of famine, fever, and cholera; always at his post, always cheerful, and ready to afford prompt and efficient help. He was a man of powerful frame, of great physical energy, of a highly cultivated mind, and possessed of extensive general information. Himself unostentatious, a sound practical physician, he laughed at, and abhorred, all pretentiousness and cant. Those who knew him longest and most intimately loved him most. His loss will be long felt by a wide circle of sorrowing friends.

Legal Intelligence.

IN CHANCERY.—(Before Vice-Chancellor Malins.)

Pulvermacher v. Hammond.

This was an action on the part of the plaintiff, the well-known inventor of various electro-galvanic appliances for the cure of nervous and other diseases, to restrain the notorious quack, Dr. Hammond, *alias* Henry James, Esq., Harvey Barrows, Esq., C. T. Raphey, M.R.C.S., &c., from using the plaintiff's trade-mark, and advertising colourable imitations of his chains and belts, in order to deceive the public. Mr. Glasse, Q.C., in introducing the Bill, said he wished to direct his honor's attention to the abominable artifices resorted to by the defendant or defendants; who, not content with trafficking under assumed names, and endeavouring to pass with the public as medical practitioners, actually pirated the names of many of the most eminent members of the medical and scientific professions, who had given testimonials to Mr. Pulvermacher for his valuable inventions, and advertised them as theirs. The learned counsel continued:—The plaintiff, having submitted his invention and system of flexible voltaic batteries in the practical form of bands and like appliances, to the attention and consideration of various of the most distinguished medical authorities in London, including the following: Sir C. Locock, Bart., Physician to Her Majesty the Queen, Sir H. Holland, Bart, F.R.S., Physician to Her Majesty the Queen, Sir W. M. Fergusson, Bart., F.R.S., Surgeon to Her Majesty the Queen, Sir J. R. Martin, Bart., C.B., M.D., F.R.S., Dr. E. Sieveking, Physician to his Royal Highness the Prince of Wales, and Physician to St. Mary's Hospital, Dr. R. Quain, F.R.C.P., Physician to the Hospital for Consumption, Brompton, Dr. A. Clark, F.R.C.P., Physician to the London Hospital; received from them their approval and the most flattering testimonial, and from Dr. C. Handfield Jones, F.R.C.P., F.R.S., Physician to St. Mary's Hospital. He held also in his hand the affidavits of Sir Charles Locock and Sir Ranald Martin, which distinctly set forth that these testimonials were given to none other than the plaintiff. The learned counsel further stated that the sham electrical appliances advertised by the defendants caused him considerable annoyance in his trade, for persons who had purchased belts of the defendants, and found them useless—which they undoubtedly were—refused to believe in the efficacy of his client's inventions, after having been duped by these pseudo doctors; who further gulled the public by using various affixes, such as "F.A.S.," "F.R.A.S.," "Ex-Governor of the Lock Hospital," and many other et ceteras, which really meant nothing, but served to mislead the public, thus robbing both the legitimate practitioner and the honest manufacturer of his just rights. The plaintiff therefore prayed that his honour would grant an injunction to restrain the defendants from infringing his patents, and fraudulently using the names of the eminent gentlemen referred to in his affidavit.

The Vice-Chancellor, after going through the Bill, said he feared he could not give the interlocutory injunction desired. It was admitted by the defendant that Dr. Hammond, whoever that might mean, had now gone away two years since, where to, was not known; that Henry James was a myth; and that the only person residing in the house—which to carry out the deception still further, was advertised under two addresses—was the man Burrows? It was an outrageous thing that the public should be thus deluded; and he was exceedingly sorry that, owing to a point raised by the solicitor to the defendant, the law did not enable him to grant the protection prayed for. Mr. Glasse could, however, sustains his case at the hearing and the matter stand over. It was a pity the public should be victimised by these abominably false statements.

Mr. Cotton, the defendant's solicitor, suggested that his honour had only heard the plaintiff's case.

The Vice-Chancellor said he had also heard the defendant's affidavit: anything more disgraceful he never saw.

Mr. Glasse said he should like to have some explicit opinion on the case from his honor.

The Vice-Chancellor said he had a very strong opinion against the defendant on his own affidavit. The tactics pursued by the defendant was one of systematic imposture, and he much regretted there was not somebody on the part of the public to put a stop to these things.

Mr. Glasse concurred with his honour. The injustice to the public and his client was immeasurable.

The Vice-Chancellor then directed that the cause should stand over till the hearing.

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

Dr. Hamilton.—The fact of your having received the usual addressed wrapper, *minus* the journal, goes to prove that the journal was lost through the post. Enquiries will be made respecting the miscarriage.

A Country Practitioner.—Your letter on "Traumatic Herpes," shall appear in our next.

Dr. J. Waring-Curran is thanked.

Medicine, Magic, and Witchcraft.—Referring to the above article which appeared in our issue of May 26th., we extract the following pertinent remarks from the letter of an occasional contributor:—I was much pleased with Mr. Donovan's article on Medicine, Magic, and Witchcraft, and quite agree with his concluding remarks "That the belief in Magic and Witchcraft in an ignorant superstitious age is less surprising, when we consider the performances of some expert practitioners of our own times." We have as much as ever of *this kind of practice but in various other forms*. The quacks and many of our own body are everyday examples of this, and it will not be in our generation that medicine will be emancipated from superstition, of which ignorance is the parent; this was best seen at a recent inquest in Hampshire, when no less than nine jurymen could not even write their own names. How then is it likely to be otherwise? Thanks in a great measure to the Parsons for this state of things in the 19th century. T. T. P.

Communications, Enclosures, &c., received from Professor Humphry, Cambridge; Dr. Wm. Brown, Hesket; Dr. Rogers, London; Messrs. Edmonston and Douglas, Edinburgh; Mr. Street; Mr. Turner; Dr. Johnson; Dr. Beveridge, Aberdeen; Dr. Clark; Dr. Lee, London: Mr. Worthington, Youlgreane; Mr. Baker Brown, London; Mr. Robertson, Edinburgh: Dr. Peirson, Scarborough; Dr. P. Heron Watson, Edinburgh; Dr. Palfrey, London; Mr. E. M. Stoehr, Manchester; Mr. Whatford, Brighton; Dr. Forman, Chicago; Dr. Hamerton, Anthillstown; Mr. I. Mitchell, London; A Country Practitioner, Belfast; Dr. Alfred Clarke, Shorncliffe; Dr. J. Waring-Curran, Manchester; Messrs. Gillon and Co., Leith; Dr. Day, London; Mr. Thos. Bryant, London; Mr. Harris, London; Dr. Gordon, Deputy-Inspector General, Portsmouth: Dr. Johnson; Mr. Tichborne, Dublin; M. A. B., London; Dr. Mitchell, Paris.

APPOINTMENTS.

Cumming, Dr. J., Resident Surgeon to the Royal Hospital for Sick Children, Edinburgh, vice Bell, whose term of office had expired.

Douglas, G., M.D., Medical officer to the Gateshead Dispensary, vice Wm. Jollie, M.D., deceased.

Lomax, W. J., M.R.C.S.E., Medical Officer to the Lincoln General Dispensary.

Lowe, G. M., M.B., Medical Officer to the Lincoln General Dispensary.

Mitchell, S., M.D., Physician to the Sheffield Public Hospital and Dispensary, vice Smith, resigned.

Pullar, A., M.B., Physician to the Westminster General Dispensary, vice W. H. Stone, M.B., resigned.

Thompson, Dr. E., Assistant to the Extra Physicians at the Royal Hospital for Sick Children, Edinburgh, vice Cummin.

Whiteley, Mr. B., Dispenser to the York County Hospital, Dispenser to the New Leeds Infirmary.

VACANCIES.

Newton Abbot Union.—Medical Officer. Salary £47, with extras.

Mullingar Union.—Medical Officer. Salary £90, exclusive of vaccination and other fees. See advertisement.

St. George's Dispensary—Honorary Physician. Election June 29th. See advertisement in our last.

PURE TASTELESS COD-LIVER OIL

IMPORTED BY BEWLEY AND DRAPER.

IT is this OIL, the use of which is directed by the MEDICAL COUNCIL, and which is ordered by the BRITISH PHARMACOPŒIA.

DR. PEREIRA

Says, "The FINEST OIL IS THAT WHICH IS MOST DEVOID OF COLOUR, ODOUR, and FLAVOUR."—"No other Livers but those of the TRUE COD can be obtained for the preparation of Oil at Newfoundland," a fact which is the best guarantee of the GENUINENESS OF THIS OIL.

In bottles, price 1s., 1s. 6d., 2s. 6d. and 4s. 6d.

Also, BEWLEY and DRAPER'S

ETHERIZED COD LIVER OIL,

AFTER THE FORMULA OF

DR. BALTHAZAR FORSTER.

Sold by BEWLEY and DRAPER,

23 MARY STREET, DUBLIN.

And May be had from all respectable Apothecaries in Town and Country.

SIR J. MURRAY'S

PURE FLUID MAGNESIA

IS RECOMMENDED BY PHYSICIANS SINCE 1807 for Bile, Acidities, and Indigestion. They also order his CORDIAL CAMPHOR (3 grs. per ounce) as the best restorative for weak nerves or low fevers. His LEMON SYRUP, mixed with either Fluid, forms a brisk Aperient for any age—bottles 1s. and 2s. 6d. To guard against false liquids the Patentee's labels are subscribed "Sir J. MURRAY, Physician to the Lord Lieut."

SAVORY & MOORE'S PANCREATIC EMULSION

Agreeable to the Taste. Readily Miscible in Milk, Water, and Wine. Not deteriorated by keeping.

N.B.—The "Reports of the Experience of Medical Men," &c. (Churchill and Son), and of Cases treated with the Emulsion, published in the 'Lancet,' 'Medical Press,' &c., are founded on the use of SAVORY and MOORE'S PREPARATIONS ONLY.

PANCREATINE "Acts on azotized food, either alkaline, acid, or neutral, three times quicker than the gastric juice, pancreatic digestion, being forcibly very rapid."—BARON CORVISART, 1859.

PANCREATINE, in Powder.

PANCREATINE WINE.

PANCREATIZED COD-LIVER OIL. The Labels give a test for Pancreatine, and a formula for making the Pancreatic Emulsion.

NOTICE.—The above are supplied in bulk for Hospital and Dispensing purposes.

SAVORY and MOORE'S

FOOD FOR INFANTS.

"THE BEST PREPARATION. Resembling mother's milk as closely as possible."—Dr. T. H. BARKER.

"A REAL IMPROVEMENT on the ordinary kinds of Liebig's Food."—LANCET.

NO BOILING OR STRAINING.

Tins, 1s., 2s., 5s., and 10s.

143 NEW BOND STREET, AND ALL CHEMISTS.

TINCTURA CARBOLATIS IODINII,

OR

COLOURLESS TINCTURE OF IODINE.

THE ADVANTAGES OF THIS TINCTURE (being colourless) is self evident. The addition of a few drops of CARBOLIC ACID and GLYCERINE to the Iodine and the Iodide of Potassium, in solution, renders this Tincture of B. Ph. perfectly colourless.

CHRONIC BRONCHITIS WITH PROFUSE SECRETION.—In this condition a trial is now being made in the hospital of the inhalation of steam slightly charged with the carbolate of iodine or colourless tincture of iodine, a preparation made by Dr. Evans, of Dawson street, which seems suitable for exhibition in this form, though its great excellence lies in its virtues as an external application. The use of the ordinary tincture of iodine to enlarged glands in the neck, has the serious disadvantage that, by reason of the ugly mark it leaves, it prevents those who use it from appearing in public, while they are the very persons to whom fresh air is so necessary; this elegant preparation, on the contrary, may be applied freely without the least discolouration, and without producing any severe irritation, which experience has shown to be injurious in such cases.—MEDICAL PRESS, April 21, 1869.

J. EVANS, STATE APOTHECARY,

49 DAWSON STREET DUBLIN.

EFFERVESCING

COMPOUND CITRATE OF POTASH WATER.

IN a Series of Lectures on Gout, Rheumatism, Rheumatic Gout, and Sciatica, published in the *Lancet* by Dr. FULLER, attention was drawn to the extraordinary virtue of Citrate of Potash in neutralising the acid products of indigestion and in ridding the blood of the uric acid and other acid materials. In confirmation of this opinion Dr. ROBERTS, of Manchester, in an admirable paper published in Vol. XLVIII of the "Transactions of the Royal Medico-Chirurgical Society of London," proves, by a series of elaborate experiments, that the solvent power of Citrate of Potash in gouty urinary deposits exceed that of Lithia and all other alkalies, and when combined with certain materials calculated to correct acidity, proves the most valuable of antacid and gouty remedies, neutralising the acid which exists in the blood, and preventing its being passed through the kidneys in the form of gravel. It is very agreeable and refreshing Two or three bottles may be taken daily.

PREPARED ONLY BY W. TWINBERROW AND SON,

2 EDWARD STREET, PORTMAN SQUARE; AND 45 WESTBOURNE GROVE, LONDON, W.

GLEANINGS IN TOXICOLOGY.

No. V.

By Charles Meymott Tidy, M.B., M.S.,
Joint Lecturer on Chemistry at the London Hospital.

I propose in the present paper examining some of the tests for strychnia, and their comparative values.

And the first I may mention is its intensely bitter taste, a test of extreme delicacy. A solution containing a grain in a gallon and a half of water is perceptibly bitter. The taste of residues is remarkably suggestive in medico-legal inquiries. The alkaloid itself I need scarcely say is very much more bitter than its salts.

The shape of the crystals vary. I do not think this is a matter of very much moment in toxicological researches, as we are almost certain to be able to prove its existence very satisfactorily by means of chemical tests, if we have enough of the material for microscopic examination. I may add, however, that the crystals sometimes assume the form of long rectangular prisms, at other times of octahedra, and occasionally of dodecahedra, the shape depending, as I have already mentioned, on the solvent employed.

But the colour tests are those upon which in medico-legal cases we principally rely. The best mode of carrying out the process is to place the strychnia or suspected matters on a clean white plate in a good light, take a drop of pure concentrated sulphuric acid upon the end of a glass rod, and thoroughly mix with the substance we are examining. Take care that the sulphuric acid is entirely free from nitric acid, as this would, as I shall point out directly, seriously interfere in some cases with the results. Then take on the point of a penknife a small quantity of either peroxide of manganese or lead, and place it by the side of the mixture on the plate; then with great caution, stir the acid so that it may come in contact with the smallest possible trace of the peroxide, and in this way the colour is certain to be developed. The great point to attend to is, only to add in the first instance, the smallest conceivable portion of the peroxide.

Now with respect to the reagents used, there are various substances recommended. The first of these is bichromate of potash. I never employ it now, because I consider it so very uncertain. For, in the first place, not only do organic matters in the form of vegetable acids, or gum, or sugar, &c., hinder, or at any rate mask its action, but when even a trace of nitre, or common salt, or indeed any nitrate, or chloride, or a trace of tartar emetic is present, the reactions are seriously interfered with. I had occasion, a short time back, to examine a powder, which I found afterwards was a mixture of sugar and strychnia. I certainly should not like to have spoken positively as to the presence of the strychnia from my experiments with the bichromate and sulphuric acid, had I not made others with different reagents.

Then again, the colour which is produced when you mix sulphuric acid and bichromate of potash is itself so intense, that it is very likely to complicate results, and leave us in a state of some uncertainty. Now, of course it may be said, surely the black mixture of plumbic peroxide with sulphuric acid is far more likely to hide the colour then the red tint with the bichromate, but one finds in practice that this is not the case, and that it is far easier to see the play of colours even when mixed with a black powder than when we have to contend with dense shades of red. And, lastly, I am at a loss to understand why so many toxicologists recommend the bichromate of potash, when it is of all tests the least delicate. With both the plumbic and manganic peroxide I have been able, with care, to detect the 1-5,000th of a grain of strychnia, but the 1-3000th, is the smallest quantity with which you can get an ordinarily safe result with potassic bichromate.

It is right, however, to say that nitrate of potash, to a certain extent, interferes with the action, when even peroxide of manganese is used, but neither common salt or tartar emetic (which I have mentioned as interfering with the bichromate of potash) have any action, or are any hindrance to the employment of peroxide of manganese. I would even say that peroxide of lead is preferable to all, as nitrate of potash must be present in very great excess to interfere with its action. I have not a doubt that the reason why few toxicologists recommend these re-agents is the fear that the colour produced may in a great measure, be hidden by the black powder, but after considerable experience I am convinced there is not the least fear of this being the case, unless (which is quite unnecessary) the oxide is added in large quantity.

And now what is the "modus operandi" of this test. It is a case without doubt of the action of *nascent oxygen*, that is of oxygen at the moment of being set free, upon the alkaloid. Dr. Letheby acting on this idea has proposed one of the most elegant modes with which we are acquainted of detecting the poison by submitting it to the oxygen evolved by means of the galvanic current. In this way the production of the colour is in our own hands. We can at once stop the action if we please by detaching the battery, and so stopping the evolution of the oxygen; secondly, it is free from every known source of fallacy; and, lastly we have no extraneous tints of any kind to interfere with a perfect recognitiou of the colour. In a case of poisoning by strychnia referred to me some time back by Mr. Lewis, I used this test with highly satisfactory results.

There are still a few other chemical tests for strychnia to which I am desirous of directing attention, although I do not think they are in the first instance of much service in medico-legal enquiries, when we have so many important and delicate tests at our command, but it is certainly most desirable that they should be used, if possible, as confirmatory evidence, of which it is impossible to have too much when life and death are dependent on our evidence.

I will endeavour to give the reactions in what I consider the order of delicacy, an order the result of a very large number of experiments, and which in many respects differs from that given in most toxicological works.

1.—The most valuable of these tests is *Iodine*. The following is the best plan of carrying out the experiment. Place on a microscope glass a very small drop of an alcoholic solution of iodine, let it evaporate, *directly* it is dry add a drop of the strychnia solution, acidulated with acetic acid, to which is added a trace of sulphuric acid and a drop of spirits of wine. (I would say to see these reactions, a solution of a trace of strychnia in three drachms of acetic acid, one drachm of spirits of wine, and six drops of dilute sulphuric acid gives very good results.)

When it has dried spontaneously, examine under the microscope with a Nicols prism and selenite, using no analyser, but merely a common eyepiece. The following characteristic figures will be seen.

(*a*) Small tufts, mostly circular, of acicular black crystals, as fine as needles.

(*b*) Myriads of minute dots of a somewhat triangular form, some being large and well defined. They are generally coloured, yellow, pink, and green.

(*c*) Large triangular crystals generally of a yellow or greenish colour, and composed of three parts radiating from a centre.

(*d*) A number of solid macled prisms, presenting here and there complementary tints of red and green.

(*e*) Solid rosette macles of four, five, and six sided prisms. These, however, were not so abundant unless the strychnia was added to the iodine solution when it had completely evaporated.

(*f*) Lastly, when the strychnia is in any quantity, large feathery and tubular plates of a colourless salt of strychnia not combined with iodine are apparent.

There are other ways in which the experiment may be made. The forms I have described are sometimes well displayed by dropping a mere fraction of a grain of strychnia on an alcoholic solution of iodine to which a trace of acetic acid has been added. There is another method by which I have obtained very good results; namely, by touching a glass slide with a drop of acetic acid, then with a glass rod touch this with a solution of iodine so as to colour the liquid slightly yellow, and then add a mere trace of dry strychnia; instantly a deep red brown colour appears, and this in a few minutes changes to orange yellow. Place over this a covering glass, and on examining it with a microscope, one or other or all of the several varieties of crystals I have described will be seen. If the acetic acid is added afterwards, myriads of minute acicular and somewhat macled crystals are generally developed. I consider the acetic acid should be added at the first as better results are in this way obtained. There is no difficulty by this means in detecting the 1-2500th of a grain.

2.—*Iodide of Potassium* produces an amber coloured precipitate, appearing under the microscope as minute triangular dots, or else as small prisms arranged in rosettes. Will detect 1-2000th of a grain.

3.—*Carbazotic acid* produces a pale yellow precipitate, appears under the microscope at first as minute needles serrated at the edges, or rosettes of minute serrated crystals. After a time these form groups of acicular prisms branching off from each other like feathers, or arranged in radiated tufts. Will detect 1-2000th of a grain.

4.—*Chloride of gold.*—Pale yellow precipitate. Myriads of little rosettes, and nodules composed of small granules or of minute acicular crystals. After a time, and especially about the edges of the liquid, the nodules break up, and form needle-shaped and rectangular plates, or the nodules become covered with very minutes spiculæ which radiate from them in all directions. Will detect the 1-1500th of a grain.

5.—*Chloride of Platinum.*—Nearly the same forms as described above, but the crystals composing the rosettes are not so well defined. The test I think is scarcely so delicate.

6.—*Bichloride of Mercury.*—White precipitate; the crystals much the same as the two last, but larger and somewhat feathery, curving into each other, or else compact nodules of minute acicular prisms. Will detect 1-700th of a grain.

7.—*Perchloride of Iron.*—A yellow precipitate; crystals are large octahedra. Will detect 1-100th of a grain.

8.—*Tannic Acid.*—White precipitate (which happens with nearly all alkaloids).

It is also precipitated by *bichromate of potash* (yellow) by *sulphocyanide of potassium* (white), by *perchloric acid* (white); by potash, soda, ammonia, and their carbonates; but these precipitates I have not as yet, fully examined, nor are the reactions of much importance.

In my next paper I propose examining the action of the poison on frogs, and its extreme delicacy, as a means of detecting its presence.

◆

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.;

Deputy Inspector-General of Hospitals.

(Continued from page 410.)

FEVERS.

Fevers as a distinct class of diseases, although numerically more prevalent among troops in India than among those in temperate climates, are far less fatal than under the latter circumstances. Thus, taking the statistics of the 10th Foot for a period of thirteen years, during which time the corps saw a good deal of service, and was stationed at various places in that country, the average annual occurrence of all types of fevers was: among soldiers 4·09 per cent., officers 5·32, women 2·64, and children 1·30; the ratios of mortality to cases being 2·88, 1·41, 4·63, and 11·33 of these classes respectively. From these figures we learn that officers manifest the greatest liability of the classes enumerated to become attacked by fever in some of its forms, but that among them mortality is at its minimum. Children, on the other hand, are comparatively seldom attacked, but when they are so are more liable to death by this cause than either of the three other classes.

Their prevalence is materially influenced by season, geographical position, and by local peculiarities of station; thus, periodic fevers prevail in Bengal in July, August, September—that is, during the three rainy months—and are most severe in the early, and again in the latter, portion of that period. During October and November, although their rate of prevalence is still considerable, the alternations of temperature between day and night being apparently a powerful cause of the continuance of attacks of intermittents in those already subjects of that form. Fevers of all kinds still further decrease in frequency, and during January, February, and March are at their minimum. Direct exposure, as during field service, did not appear to produce material increase in the severity of attacks of fever, and under such circumstances the treatment necessary was found to be more simple than in quarters; frequent affusion being the only measure demanded by cases of continued fevers, while in those of intermittents comparatively small doses of quinine were administered.

Intermittent Fevers.—Statistics indicate that fevers of the intermittent type increase in prevalence according to length of service of soldiers in India; that the distinctions are seldom well marked between the different types of these, and that, although mortality is small indeed by uncomplicated ague, the fact of a person manifesting a liability to recurrences of the disease may be taken as an indication of a tendency to organic affection which may destroy life; and that, therefore, removal out of the country for a longer or shorter period is in such cases absolutely necessary. Of the various classes of persons comprising a regiment, soldiers are the most liable to these affections, next to them the officers, then the soldiers' wives, and, least of all, the children. With regard to mortality, however, no death by intermittent fever except among soldiers and children is recorded as having happened in the 10th Foot during thirteen years it served in the country.

Of 1,672 cases of this form of fever which occurred among soldiers, 1,151 were of the quotidian type, and 521 of the tertian; of 48 among officers, the numbers were respectively 22 and 26; of 130 among women, 109 and 21; and of 74 among children, 65 and 9. Thus, the quotidian was the type most prevalent among soldiers, their wives and children; the tertian was slightly the more common among officers.

On two occasions during the service of the 10th Regiment in India intermittents prevailed as epidemics in the corps. On both of these a heavier rainfall than usual had taken place; no perceptible difference in other meteorological conditions was, however, observable between them and others where the disease did not prevail, and it may be said that the physical causes of the disease were inappreciable.

It should be mentioned that one of the occasions when the disease prevailed in this manner was when the corps occupied temporary barracks at Wuzzerabad, in the Punjaub, a low lying sandy site, little elevated above the level of the River Chenab, which flowed past it at a distance of about four miles. The layer of surface sand rested upon a bed of stiff clay, containing calcareous nodules; and notwithstanding that, during a great part of the year, the vicinity presented little vegetation, water was at all times to be found in abundance at a depth of not more than six or eight feet.

There are not a few men and officers who have spent many years in India who suffer at irregular and uncertain intervals from attacks of intermittent fever, in whom such attacks would appear to have become habitual, and whose health seems to be temporarily renovated after each. Among those who manifest this liability, an accession may frequently be induced by slight exposure to the sun, night air, a draught of wind, by irregularity in diet, by mental annoyance, or other circumstances that do not affect the robust.

An explanation of such peculiarity is among the difficulties which beset the medical officer in that country. Perhaps we may assume that the particular influence upon which the phenomena of ague depend being imbibed into the system of an individual, it there undergoes a series of changes, and produces particular trains of symptoms according to the degree of *impressionability* of the individual to it; thus, in one person the vital powers may be such that the system eliminates the poison without becoming itself affected thereby. Such cases, however, are of comparatively rare occurrence; but that they do happen is a fact familiar to all of local experience, persons being known to them who for many years have lived in notoriously malarious and aguish localities without being in any way affected thereby. The very much larger and less fortunate classes include, in the first place, persons who, from temporary exposure to concentrated causes of fever, or to protracted exposure to them in a less concentrated form, become the subjects of that fever called respectively remittent, jungle, or marsh fever; and in such cases, provided the patient has sufficient strength to bear him through the original attack, he is left cachectic, anæmic, and greatly debilitated. In the second, we take the case of a strong healthy young man, a keen sportsman, and a person who has for a certain number of years exposed himself in all manner of ways without injury, and whose boast therefore is that "the sun has no power to hurt him." Suddenly, and, it may be, without adequate cause, he is attacked with ague; he goes through the regular stages of a seizure of this kind, and then returns to his ordinary habits. Soon, however, he is "down" again; and so on, time after time, until he is reduced to a condition in which removal to a cold climate becomes for him a necessity. Shall we suppose that in such a case the morbific influence has gradually accumulated in the system, defying the vital powers to throw it off, and that, by its continuous presence and accumulation, the functions become impaired and weakened in the manner just described?

It by no means necessarily happens in India that a person undergoes an attack of the more dangerous form of fever before he becomes the subject of ague. The latter form may be the first, or indeed the only one with which during his residence he may be affected; while, on the other hand, he may have successive attacks of the continued type without being subject to ague. In this respect there is, I think, a great distinction between the manner in which persons stationed respectively in India and on the West Coast of Africa suffer from these affections. On the Coast of Guinea it is, or rather *was*, in 1847-8, observable, that in the case of a white man arriving there for the first time, it mattered not whether he had previously been subject to intermittent fever, he must first undergo an attack of the ordinary endemic fever of the Coast before the ague becomes re-established. So also in the West Indies, the circumstance of a person being the subject of *fever and ague* was at that time considered as indicating his non-liability to the more severe forms, and in that sense the occurrence of the cold stage of intermittent fever was considered a subject of congratulation. I myself have been thus congratulated at Cape Coast Castle. Probably ague was looked upon as a kind of safety-valve to morbid influences that might otherwise induce more serious results.

This type is most common in the months of July, August, and September, or, in other words, during the rainy season. During October and November it also prevails to a considerable extent, but decreases from that time till March, when its prevalence is at its minimum. It does not always happen, however, that individual obtains benefit by the advent of the cold weather, which serves to restore and "set up" the health of those who, during the long months of intense heat, have been in some measure lowered, but without suffering from actual disease. On the contrary, a temporary increase both in the frequency of the attacks and in their severity often occurs under such circumstances, while some persons who had hitherto remained free from the disease now became attacked.

That attacks of rheumatism often supervene upon fevers in India is well known. In such cases that disease assumes a periodic character; but it has also been observed that a similar tendency occurs in other affections. Various other forms of disease arise as direct effects of exposure to *malaria*, one of the most frequent being enlargement of the spleen, which, as being the most frequent complication of ague, may here be made the subject of a few remarks. Its relative prevalence varies greatly according to the circumstances of particular classes of persons borne upon the rolls of a regiment in India. Thus, I find that among the cases of "fever and ague" in soldiers, already recorded, there were 127 of enlarged spleen, giving a ratio of 7·59 per cent.; among those in officers only one case occurred, or 2·08 per cent.; among all the cases of ague in women there were 7, or 5·39; and among children the spleen was affected in 13, giving the very large proportion of 17·56 per cent.

The very great liability of children to become thus affected is remarked by persons of even moderate experience in India. The little sufferers are immediately recognised by their pallid tumefied face, pale lips, protuberant abdomen, and wasted limbs; those of them whose parents can afford to send them home should be sent to England without delay, and it is to be hoped that with the large extent of accommodation for troops now being prepared in the hills throughout India, ample means will be provided there for their wives and children affected with this disease and with the many other forms which render a removal from the plains necessary for their recovery. Under existing circumstances, mortality from this cause and its attendant cachexy is among the young very considerable.

◆

SUCCESSFUL TREATMENT OF PROLAPSUS ANI BY THE "ECRASEUR."

By **Daniel Donovan**, M.D.,
Physician to Skibbereen Workhouse.

John Mahoney had been for the last five years under my care for protrusion of the anus and mucous membrane of the rectum, occasioned by dysentery and diarrhœa, under which he had for a long period suffered. Finding that the use of astringent injections and other means of treatment were ineffectual in arresting the disease, I determined on submitting him to an operation; and for this purpose had four longitudinal strips cut out nearly the whole length of the protruding prolapsus. Fearing that undue hæmorrhage would result, as the protruding portion appeared very vascular, I determined upon applying the "ecraseur," and tightening it to such a degree as would ensure the destruction of the protruded part by the process of sloughing, without interfering with the passage through the bowels. After the instrument had been applied about an hour, the protrusion became black and livid, and felt cold to the touch, the sloughing appearance increased, and after two days the protruding portion sloughed away. Poultices were then applied, the slits put on a healthy appearance, and in about a fortnight contracted almost entirely, and speedily healed up.

Since then there has been no recurrence of the disease; the patient appears perfectly healthy, and has not at all suffered from protrusion since the date mentioned.

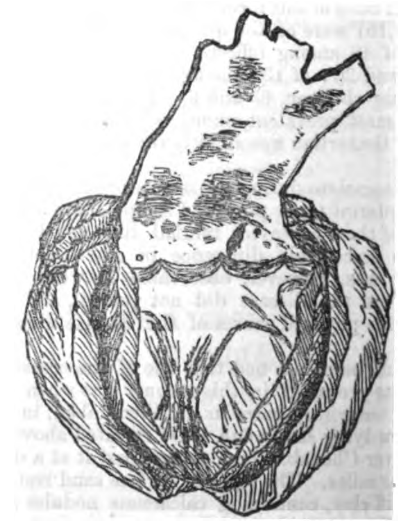
ON THREE CASES OF ANEURISM OF THE AORTA, WITH RUPTURE INTO THE PERICARDIUM, OCCURRING WITHIN A SHORT PERIOD OF EACH OTHER, IN THE GARRISON OF PORTSMOUTH IN 1868.*

By J. **Lamprey**, M.B., Surgeon 67th Regiment.

Whether it is owing to more attention being drawn to the subject of aneurism, and fewer cases of the disease escaping detection, or to a difference in the circumstances affecting the physical condition of the soldier, it is difficult, perhaps, to say; but this formidable disease has apparently become of such frequent occurrence that the army surgeon is obliged to take a special interest in it, as it occasionally requires him to exercise his surgical skill in performing important operations for its cure, or, when beyond the reach of operation, as in the cases of some inter-thoracic and abdominal aneurisms, to record, the physical signs of the disease, during the life of the individual, with the view of the inevitable fatal termination affording the opportunity of verifying diagnosis by post-mortem examination.

It is seldom, perhaps, that three such cases, of which the following is a brief record, come under our notice; the three cases being remarkable for their resemblance to each other, for their occurrence within a short period of each other, and for their fatal termination by rupture into the pericardium.

The first case of this peculiar form of disease occurred in a man of the 35th Regiment, aged thirty, and of nine years' service, who died suddenly while engaged at running drill in barracks on the 8th of June last. The post-mortem examination revealed a small aneurismal pouch at the base of the aorta, just above the semilunar valves, and close to the coronary artery. It was about the size of a marble, and had a small fissure or rent leading into the pericardium, which was filled with blood, the heart being encased in a mass of solid coagulum. There was no valvular disease, nor altered structure of the heart, except that it was somewhat fatty. The coats of the aorta at its base were thickened, and presented a rough puckered appearance around the opening leading to the aneurismal pouch.



Showing the slit-like opening into the aneurismal sac close to posterior attachment of the outer semilunar valve of the aorta, the atheromatous deposit on the valve, and patches of atheroma on the internal surface of aorta.

---

* Read before the Portsmouth Medico-Chirurgical Society.

This heart was exhibited to the Army Medico-Chirurgical Society at Portsmouth by Surgeon Poulton, of the 35th Regiment.

The second case occurred in the 67th Regiment, æt. twenty-seven, service eight years. On the 30th of May, 1868, while marching in heavy marching order across the Curragh of Kildare with his regiment, from the camp to the railway station, was suddenly seized, after marching about a mile and a half, with a very distressing attack of dyspnœa, so that he was obliged to fall out of the ranks and have his knapsack removed from his shoulders. A few moments' rest enabled him, with the assistance of his comrades, to get to the railway station. When admitted into hospital at Portsmouth on the 2nd of June, 1868, it was ascertained that the cause of the dyspnœa was not any abnormal organic condition of the lungs, but was owing to an aneurism of the aorta; at least, the physical signs were indicative of that disease—viz., there was a loud blowing murmur audible over the course of the ascending aorta, more distinctly in the upper part of its course, and in the carotids, and especially loud at the cartilage of the second rib. There was no bulging forward of the sternum, but there was tumultuous action of the heart visible externally. The area of precordial dulness was not enlarged. Both sounds of the heart could be heard most distinctly much below the ordinary position where the valve sounds are best heard; they could be most distinctly heard at a point below the left nipple, and were still audible at three or three and a half inches below it. A bruit close to the commencement of the aorta was heard accompanying the first heart's sounds. Neither sound was defective. The pulse was accelerated, and the inspiration was short and hurried, and when he spoke it was with a hurried abruptness, owing to loss of breath. He also complained of shooting pains extending to the left shoulder-blade and spine. Severe pain was also felt in the cardiac region. Shortly before his death, which occurred on the 21st of July, the severity of the dyspnœa increased to a great degree. There was swelling of the epigastric region of the abdomen, and puffiness of the face and chest, and marked congestion of the veins of the upper part of sternum and the lower part of the neck.

In October, 1866, this man had been carefully examined for heart disease, preparatory to his doing running drill, but there was no indication of it discovered. He stated that he did feel shortness of breath, and was otherwise distressed after running, but did not complain.

The case was diagnosed as one of aneurism of the ascending aorta, displacing the heart downwards.

At the post-mortem examination, the pericardium was found distended with serum, and containing more than eight fluid ounces of recently-coagulated blood. The aorta to the entire length of the ascending portion was dilated to three times its natural capacity, and was, to some extent, but not much, thickened and roughened on its inner side. The semilunar valves were thickened, but not deficient, nor in any other way diseased. Within the left aortic sinus there was a small bulging, into which the tip of the forefinger might be thrust. The volume of blood impinging here at each action of the heart gradually thinned the part, and finally caused it to give way by an aperture large enough to admit a No. 6 catheter, a little below the appendix of the left auricle.

The other valves were normal. There was hypertrophy of the ventricles.

This heart was exhibited to the Army Medico-Chirurgical Society by Assistant-Surgeon Bruen, of the 67th Regiment.

The third case is that of a man of the 33rd Regiment, aged thirty-three; service thirteen years, in China, India, and Abyssinia. Admitted to hospital on the 1st September, 1868, with pains in the abdomen, extending towards the right side of the chest; in a few days this was followed by cough, much distress of breathing, and slight febrile symptoms.

On consultation and percussion, the physical signs of pleuritis were discerned in the right side; but, in addition to this, there was a loud, rough, blowing murmur audible over the cardiac region, loudest at the base, and propagated upwards. The blow accompanied the first sound, and obscured the second.

On the 5th of September he commenced to spit blood of a mahogany colour; and on examination of the gums it was found he was scorbutic. All his symptoms rapidly increased in severity; pains in the right chest became very severe, and there was considerable bulging of this. His respiration became more difficult, and his feet began to swell.

On the 9th of September the cardiac sound was altered in character, being now more like a loud to-and-fro friction sound, indicative of pericarditis. He could not lie down, on account of the difficulty of breathing, and he died at three o'clock, a.m., on the 10th September somewhat suddenly.

At the post-mortem examination, at which I was present, the pericardium was found to be much thickened and inflamed; the cavity contained fluid blood or bloody serum, but no clot. The heart was slightly enlarged: its surface was red, with some layers of lymph deposited on it (pericarditis). There was considerable deposition of atheromatous matter on the free margin of the left sigmoid valve; the other two valves were in their normal condition. Directly above the diseased valve, and to the inside of the orifice of the left coronary artery, there was a large opening in a vertical direction in the corresponding aortic sinus; this led into an aneurismal sac, capable of containing a large-sized filbert. It occupied the space between the aorta, left auricle, and pulmonary artery. The farthest extremity of the sac was very thin, and presented a lacerated appearance, making a large rent. Where the sac was in contact with the auricle, there was a marked thinning of the wall of the auricle, so that it might possibly have burst into it. The walls of the sac consisted of the inner and outer coats of the aorta. The origin of the aneurism would appear to be owing to the giving way of the middle coat, through a friable condition of the fibres comprising the structure of that coat of the aorta by the deposition of atheroma in it. The patches of atheroma throughout the ascending portion of the aorta, and extending to the margin of the opening of the aneurismal opening would favour this view.

I found, on examination of the structure of the arterial coats, in a part where this atheromatous deposit existed, the fibres of the middle coat were very friable and thickened, and when seen under a high power of the microscope, the fibres appeared to be interspersed with nucleated cells of very irregular form. The eliminations on the internal surface of the artery were chiefly owing to thickening of the inner coat; when seen under a high power, this coat was observed to be thickly interspersed with nucleated cells also.

There appeared to be endocarditis as well as pericarditis in this case; and on opening into the pleura on the right side, recent honeycombed lymph was found deposited on the base of the lung, and the pleural cavity contained serous effusion.

With the exception of enlargement of the liver, the abdominal viscera appeared to be healthy.

Judging by the atheromatous condition of the aorta and the rounded margin of the entrance into the aneurismal sac, the aneurism must have existed long prior to the occurrence of the pericarditis or pleuritis, and no doubt the accelerated action of the heart, consequent on the acute inflammation of the pericardium and pleura, aided in the expansion and final rupture of the aneurismal sac.

Surgeon-Major Sinclair kindly allowed me to lay this case before the Army Medico-Chirurgical Society.

In the first case there was no opportunity of observing the symptoms during life.

In the second case, the aneurism was diagnosed during the life of the individual. It was supposed to be confined to the ascending portion of the aorta; and had there not been a rupture leading into the pericardium, the existence of an aneurismal sac close to the valves, the rupture of which was no doubt the immediate cause of death, would have been overlooked. The existence of distinct bruit over the valves accompanying the first sound, would appear to be in connection with the small sac which was found in that position. But the existence of the greater lesion in the aorta above caused more attention to be given to it during the life of the individual.

In the third case there was a loud blowing murmur audible over the cardiac region, loudest at the base,—"the blow accompanied the first sound." In this case it would appear that death did not immediately follow the rupture of the sac into the pericardium.

In the last volume of the Army Medical Report, for 1866, vol. viii., there is an account of a case of aortic aneurism of a similar description to the foregoing cases, and, like them, having a fatal termination by rupture into the pericardium.

The existence of aneurism was diagnosed during the life of the individual, a soldier of the 5th Dragoon Guards, by Surgeon Ovens, who reports the case. The chief sign indicative of the disease was "a well-marked systolic bellows sound, audible along the entire course of the ascending aorta, but which seemed to increase in intensity the nearer the stethoscope was placed to the heart; there was also well-marked evidence of the enlargement of this organ.

In describing the post-mortem appearance, he says: "the source of the blood"—that found in the pericardium—"was found to be from a ruptured aneurismal pouch, so near the root of the aorta as to project within the pericardium." In this case the portions of the sac in reference to the orifices of the aortic sinus is not particularly stated; but in the three cases to which this notice has more especial reference there was a remarkable similarity of position, the aneurismal sacs having occupied the space defined by the pulmonary artery in front, the left auricle posteriorly, and the aorta internally.

It is a matter of no small importance to define the exact position of the sac, or bulging of the coats of the aorta, more especially in relation to the valves, sinus, and orifices of the coronary arteries in all cases of aneurism, in their vicinity as such cases are apt to terminate fatally without any previous warning of the existence of the disease. It shows the necessity of making periodical examinations of the heart's action of each man of a regiment, and recording any abnormal sound or action of the heart that might be detected, however trivial it might appear.

Literature.

BRONCHITIS IN CONNECTION WITH GOUT, EMPHYSEMA, AND HEART DISEASE.*

This volume consists of lectures delivered during the last two years at the Middlesex Hospital, of which the author is the Senior Assistant-Physician. The lectures were delivered apparently at occasional intervals, and therefore there is a certain degree of disconnection and redundant explanation, for which Dr. Greenhow duly apologises in the preface, but which in no wise detracts from their value as clinical lectures.

Taking the subject of gout first, as that is put first in the title, so assured does the author feel of an intimate association between bronchitis and gout, that he makes a sub-division of gouty bronchitis, to which he devotes two most interesting lectures. He traces the co-existence of the two diseases not only in individuals, but in families. He has remarked also habitual alternations of gout and bronchitis in persons subject to both diseases, and also similar relations between psoriasis, eczema, gravel, stone, albuminuria, gout, and bronchitis.

We have for years publicly taught that there are many relations and analogies between diseases which are constantly ignored, and we therefore welcome so able an observer as Dr. Headlam Greenhow among those who see clinically the very things we have believed that we too have detected. Our author treats such cases, when acute, by colchicum, iodide of potassium, &c., combined with squill and henbane; and we can endorse his recommendation. In these days of scepticism as to remedies, it is also refreshing to find the hold that colchicum has upon a careful physician. Dr. Greenhow sees its use in the acute paroxysms of gout, but he does not believe with its enemies that it increases their frequency, nor does he think it really lowers the patient. Moreover, he credits it with the power of lessening the tendency to gout, provided it be given regularly for a considerable time, of course in small quantities. We have met observant men who had equal faith in it.

We have found several other practical points in this book which completely bear out our own experience—an extensive one in these diseases—and we have therefore much pleasure in calling to it the attention of practical men. The relations between bronchitis and heart disease are more generally understood, so that we have confined our observations to "gouty bronchitis." We would not, however, have it thought that we consider the other portions of the volume less carefully worked out. Dr. Greenhow does not claim to have exhausted the subject of chronic bronchitis. That would be impossible to accomplish in a handy little volume of 220 pages; but he certainly has set forth the intimate connections of that disease with certain general and local conditions in so clear and patient a manner as to deserve the commendation due to an industrious contributor of clinical records.

There are in this work no less than forty-six carefully condensed cases, which illustrate and enforce the opinions put forth, and are, in fact, the groundwork of the treatise.

A Feigned Tumour of the Jaw.—Emamun, a Mussulmani, aged fifteen, was brought to me on November 20th by her parents. They stated that upwards of a year before they had observed a small tumour near the angle of the lower jaw on the left side. It continued to increase slowly; native practitioners failed to give relief; and at last, despairing of a cure, they had brought her to have it removed by operation. There was a tumour on the left side of the face, rounded, of the size of a tea-cup. The skin slid easily over it, and its most prominent part was dusky red, and apparently on the point of ulcerating. The tumour was firm, of a bony consistence, and seemed equally connected with both jaws. The lower jaw was fixed, the mouth nearly closed, and the girl complained of great pain. In spite of the suffering she had undergone, she had not lost flesh, and the right cheek was plump and rounded. On separating the lips, to inspect as far as possible the interior of the mouth, I observed the ends of two flat bands of a black colour which hung from the tumour into the mouth. On inspecting these somewhat minutely (which was a matter of some difficulty, as she was perpetually starting back, and complaining of great pain) I noticed certain lines which seemed to me to indicate either that the bands were pieces of cloth inserted into a cavity in the tumour, or that cloth of some sort had been recently placed in contact with them, so as to leave its impression. I asked the parents if any cloth had been introduced into the mouth; but they asserted that such was not the case, and the girl corroborated their statement. I now seized the band with forceps, and, using a little force, succeeded in removing it; the girl shrieking loudly, and endeavouring to seize my hand. The band was simply a piece of cloth. On examining the mouth I saw what was undoubtedly a second piece of cloth, which I also removed, and thus I went on removing piece after piece till every vestige of the tumour disappeared. The girl looked foolish and sulky. The parents seemed stupified, and could not at once realise that their daughter's illness was pure deception. They brought her to me again on the following day. There was not the slightest trace of disease. The teeth were sound, the jaws well formed. The right cheek was, as I have said before, plump and round; the left was thin, and hung flaccid and void of expression. The centre of the cheek, which formed the most prominent part of the tumour was now shrivelled up, like the skin of a withered apple. The tumour was composed of twenty-three pieces of cloth, weighing, when washed and dried, 4 ounces.—Dr. Macleod Cameron in *Indian Medical Gazette*.

WEDNESDAY, JUNE 16, 1869.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE coming election of Councillors is exciting a more widespread interest than usual, and as principles of the highest importance to the profession are therein concerned, we have no hesitation in devoting more than an ordinary share of our space to the subject. We cannot undertake to print all the letters we receive endorsing our own views, and have preferred to insert the letters of candidates themselves that have been sent us in reply to our challenge to all to boldly state their principles. Other candidates have sent their manifestoes elsewhere, and others again preserve silence. We once more urge upon every Fellow of the College his duty to himself and his profession, to discard all private feeling in the matter, and vote only for men whose views he can support. The retiring Councillors who offer themselves for re-election appeal naturally to the past as their guarantees for the future. No criterion could be more satisfactory, and we doubt not that the Fellows will judge them impartially.

Mr. Solly's reply to Mr. Morris is firm and dignified, and when we remember that re-election to him virtually means promotion to the Presidency, we cannot withhold our respect for the attitude he assumes. Happily for him he says, "I have always been a reformer," without which assertion he would most certainly have been sacrificed. With it we may heartily wish him success, though we should have been better pleased had he pronounced in favour of the election of a representative in the General Council by the Members and Fellows.

The next letter we have received is by Mr. Henry Lee, of St. George's Hospital, and to this we desire to direct the attention of our readers generally, and particularly to those who have votes. It is a statement of principles of the highest importance, and deserves attentive consideration. Mr. Henry Lee is the Senior Fellow *by examination* amongst the candidates—he is Surgeon to St. George's Hospital, and to the Lock Hospital; he was formerly Surgeon to King's College Hospital—he therefore combines many influences, and has great probability of success. His writings, including his Jacksonian Prize Essay and his Clinical Observations—some of which have adorned our pages during the last two years—place him in the front rank of metropolitan surgeons, and must greatly assist him. Again, as we stated last week, Mr. Lee fully sympathises with the Provincial Fellows, and would gladly assist them in obtaining their fair share of influence in the College. This we might have expected from him as an ex-President of the Association once called Provincial, now styled British. We are further able to state that Mr. Lee will support the extension of the franchise for the election of a representative in the General Medical Council, and in this respect, like all other genuine Liberals, has arrived at the conclusion that the scheme of representation proposed by Dr. Prosser James is the one that ought to be adopted. This one question has now become the touchstone of progress. Those who will not support so simple and just a plan for giving the profession a voice in the Council, will soon find themselves left in the cold shade; and as this applies to every corporation in the three kingdoms, we have no doubt it will soon become the one question put to all candidates for office.

It is very satisfactory to notice further the general willingness exhibited to abolish all unnecessary restrictions, and throw the various offices of the College open to all who may be considered worthy by their co-electors. These reforms, with the reconstruction of the Court of Examiners, the admission of reporters to all the debates, and the right to meet in their own College, are the points which have made great progress, and on which Fellows and Members have quite made up their minds.

We have reserved till last the most important letter on this subject—that of Dr. Hearne, of Southampton, which is, in fact, a reply to a request to become a candidate. This letter has been sent us for publication, although the author is not actually in the field, his supporters intending to bring him forward next year. We print it because it contains a valuable programme, and because, during the next twelve months, the Fellows will have time to think over it; while at such a crisis as the present, its interest will be increased ten-fold. It will be seen at a glance that Dr. Hearne is far more liberal in his views than any of the candidates who have addressed us, and this letter, under the present circumstances, is ample proof of his desire to promote in every way the welfare of the profession. It sets before all future candidates a measure by which they will be judged, and is in itself a point by which to calculate progress.

Those who have not yet taken interest enough in the subject to have become alive to their rights and those of their brethren, would be fulfilling a duty in mastering the contents of Dr. Hearne's letter.

◆

PROCEEDINGS OF THE DUBLIN OBSTETRICAL SOCIETY.

CONTINUATION OF THE DISCUSSION ON PUERPERAL FEVER, JUNE 5TH.

DR. CHARLES FREDERICK MOORE said he would not occupy the society with any remarks on puerperal fever, as the subject had already been treated with so much ability by so many eminent physicians, except in relation to its apparent connexion with the habits of, and conditions of the dwellings, of the community.

He based his deductions on an extended experience of disease, not only in Dublin, but also in London, and in tropical countries.

Differing from Dr. Evory Kennedy, he regarded hospitals for what are called zymotic diseases as effecting an arrest of, and not the dissemination of, those diseases; and in corroboration of his position, he quoted a work published "On the Diseases of Dublin," by Dr. Martin Tuonny sixty years ago. Dr. Moore also quoted the testimony of his colleagues in Dublin, which also proves the rapid spread of infectious diseases if allowed to exist in the unsuitable and ill-ventilated tenements of the masses in our large cities and towns, and gave his experience in relation to the fatality of epidemic cholera in some eastern cities, where the sanitary condition of the people was extremely bad.

He referred to the evidence of Drs. Beatty, Stokes, Barnes, and others, as to the comparatively frequent occurrence of metria in private practice—that is, amongst persons in good circumstances.

Metria exists frequently in rural districts, and in small towns where no lying-in hospitals exist; the absence of such institutions by no means insuring exemption from the disorder, as might be inferred from hearing Dr. Evory Kennedy. The gentleman just named has no grounds for pleading ignorance on the subject of puerperal fever, as he now does, in reference to the knowledge possessed by the profession on the subject, in the seven years of his own Mastership of the Dublin Lying-in Hospital, inasmuch as Dr. Robert Lee's able paper on the subject, in all its relations to hospitals, &c., had been in existence in the "Cyclopædia of Practical Medicine" a year before Dr. Kennedy entered upon his duties.

Dr. Moore argues that it is not in lying-in hospitals the predisposition to the disease is formed, but rather in the laxity of fibre and debility, which tend so greatly to cause hæmorrhage and other severe accidents in labour, and which but too frequently end in puerperal fever, if the epidemic constitution be present at the time; and he believes that this receptivity is originated in the mentally depressed and otherwise unhealthy room-keepers of large towns.

In confirmation of this opinion, he gave some details of cases in his own practice and observation; he also dwelt upon the relationship between scarlatina and puerperal fever, quoting the occurrence of eleven deaths by the latter disease at Maidenhead in October and November, 1865, during which period sixty-six births were recorded in the same locality. Scarlet fever was very prevalent there at the time; these cases seem propagated by certified midwives, and there was no hospital in the vicinity. Dr. Moore mentioned his experience of the injurious effects of scavenger's yards, depôts of manure, pigs, &c., and the anxiety now being evinced by the working classes to have all such removed from town, as being a great cause of disease in Dublin.

He instanced the danger to pregnant women, whose children have been carried away by scarlet fever, and urged the great necessity of separating the early cases of scarlet fever and other contagious diseases, by their removal to hospital, from healthy persons, especially pregnant females; arguing that such means, coupled with the promotion of the health and vigour of all women about to become mothers, whether intending to enter lying-in hospitals or remain at home, constituted the most sure preventative of puerperal fevers or other illness.

He read a letter from Mr. Sandham Symes, an eminent architect, shewing the impractibility of attempting to conduct the duty now performed in the Dublin Lying-in Hospital in detached cottages in the Rotunda Gardens.

In conclusion, he pressed upon the Society the importance of sanitary measures for the diminution of metria, especially if it was true that the disease was increasing of late years. If such was the case, however, it resembled in that respect diarrhœa, dysentery, diphtheria, and allied diseases.

◆

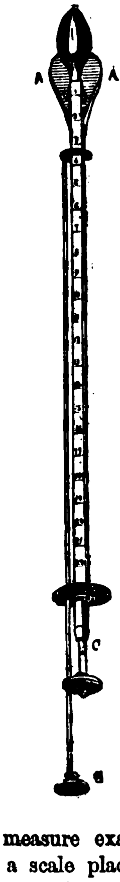
Notes on Current Topics.

A New Rectotome.

At the sitting of the Academy of Medicine of Paris, on the 21st of April, Dr. Tillaux, of the Hôpital St. Antoine, presented a rectotome, constructed, at his suggestion, by Messrs. Robert and Collin. By the aid of the instrument Dr. Tillaux proposes :—

1. To measure exactly the length of the constriction by the help of the slide B., which is moved with a graduated screw nut.

2. To make incisions through the entire length of the constriction without ever touching the healthy parts. The blades A A being blunt at their greatest diameter, like as in Maissoneuve's urethrotome.



3. To graduate and measure exactly the depth of the incisions by means of a scale placed on the screw D to which the blades are attached, and to be able to bring them to bear quickly upon several points of the circumference of the constriction.

New Pharyngo-laryngoscopic Apparatus.

M. Galante has presented to the Paris Academy a new Pharyngo-laryngoscopic apparatus, which he had constructed on the designs of M. Ch. Fauvel.

This instrument is intended to remedy the following objections to the laryngoscopes now in use :—

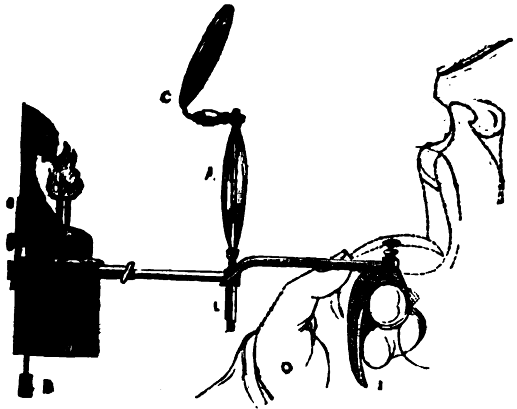
Firstly,—The impossibility of examining the patient when lying down.

Secondly,—The difficulty of procuring a convenient lamp.

Thirdly,—The time lost in adjusting the lamp.

The new laryngoscope is composed—1. Of a tongue clasp, with which the tongue is drawn out and fixed by the thumb of the left hand ; 2. A biconvex lens surmounted with a plain mirror, capable of varying in its angle of inclination ; and 3. A lamp for burning mineral spirit, which in a very small size gives enough light to see in the mirror all the parts of the growths, and, if necessary, to make applications to them.

The left hand of the operator supports the apparatus, and keeps the tongue depressed, while the right applies the laryngeal mirror, which is lightly illuminated by the attached lens. The plain mirror, inclined at a proper angle enables the patient to see the image of his own larynx.



This apparatus has been tried by its designer, and at the Hôpital of Gros Caillou, in the service of Dr. Lieberman.

Royal College of Physicians of London.

The annual conversazione of the London College of Physicians was held on the 9th, with its usual success. Fellows and Members of the College assembled in great force, and the sister College and scientific societies were well represented amongst the distinguished guests. An interesting exhibition of scientific instruments, &c., greatly amused the audience. Some of the most curious were the new direct spectroscopes, of pocket size and moderate price, and the numerous microscopic specimens. Some photographs illustrating recent solar discoveries were ably explained by Mr. Norman Lockyer, who was attended by a numerous audience. We add some other items :—

Expansion of Palladium by the absorption of Hydrogen . Shown by the Master of the Mint.
Sir Wm. Thompson's Bifilar Quadrant Electrometer.
Marey's Cardiograph . . . . Dr. Sibson.
Photographs illustrating recent Solar Discoveries, shown by means of the Electric Lamp. J. N. Lockyer, Esq.
Microscopic Slide, containing 400 classified Diatoms ; Inductorium, containing 24 miles of Secondary Wire, giving 16-inch sparks, and other Experiments ; Table Polariscope, showing the Axis of Crystals ; Pocket Spectroscope. Mr. Ladd.
The Ova of Bitharzia Capensis . Dr. John Harley.
Dr. Guy's Common-place Book. Messrs. De la Rue & Co.
Works of Art from the Private Collection of John Henderson, Esq.
Crimes of Insane Convicts ; Illustrative Diagrams. Dr. Guy.
Two large Nicol Prisms, mounted as a Polariscope. W. Spottiswoode, Esq.
Stetho-sphygmograph . . . Dr. Hawksley.
Saccharometer arranged to show the action of Magnetism on Light . . . Dr. Dupré.
Dr. Richardson's Ether-Spray Apparatus ; Siegle's Steam Spray Inhalers (various) ; Gunker's Anæsthetic Compendium for local and general Anæsthesia ; Couper's Chloroform Inhaler, especially devised for operations on the Eye ; and other objects . Messrs. Krohne & Sesemann.
A new large Electric Lamp and other Instruments. Mr. Browning.
Micro-Insects, with Drawings and Preparations ; Beckley's self-registering Rain Guage, in action ; Delicate Assay Balance, turn at 10,000th of a grain when loaded with 30 grains ; a new Clinical Thermometer, Microscopes, &c. Mr. Baker.
Powerful Medical Coil Machine, with Primary and Secondary Currents, in action, the Optic Axes of Uniaxial and Biaxial Crystals in Polarized Light ; Microscopes showing Argulus foliaceus, Halodactylus, Foraminifera (Atlantic), Palate of Limpet, &c., &c. ; Photographic Transparencies . . . . . Mr. James How.
Microscopes, including the new Tank Microscope, with novelties in Microscopic accessories. Mr. Ross.
Microscopes ; the new Panoramic Stereoscope and others ; Graphoscopes ; the Phosphorescent Butterfly ; Photographic Prints and Enlargements in Carbon, &c., &c. Messrs. Murray & Heath.
Album of Photographic Portraits ; Album of Views of the Camp at Wimbledon ; Ivory Miniatures, &c. . . . . . Messrs. Moira & Haigh.
Table Polariscope ; Specimens illustrating the Auditory Apparatus in Fishes . . Mr. C. Stewart.
The Swiney Prize Cup awarded to Dr. Guy, 1869.
Impressions from the Great Seal of England ; Impressions from the Great Seal of Scotland ; Impressions from the Great Seal of H.R.H. the Prince of Wales as Hereditary Steward of Scotland ; a frame of Medals by the late Benjamin Wyon, chief engraver of Her Majesty's Seals ; a frame of Medals by J. S. and A. B. Wyon, chief engravers of Her Majesty's Seals. Messrs. J. S. & A. B. Wyon.
Microscopes showing Circulation in the Vallisneria, Volvox Globator, Circulation of the Blood in the Branchia of the Newt, &c. Messrs. Powell & Lealand.
Dissections of the House Fly . B. T. Lowne, Esq.
Graduation of Spirit Thermometers, &c. . Mr. Ackland.
Double Wall Ice Water Pitcher, &c. Wenham Lake Ice Company.
Maxwell's Wheel of Life ; Working Model of a Steamer . . . . Elliott Brothers.
Painted Casts of Salmon and Trout ; Series of Whitebait, &c. . . . Frank Buckland.

The Election of the Council of the Royal College of Surgeons in Ireland.

The annual election, which took place last Monday week, was one of the closest and most exciting contests which the College has of late years seen. By the resignation of Mr. Wilmot a vacancy was created, and it was sought for with great ardour by Sir William Wilde, Mr. Edward Hamilton, Dr. Quinan, Mr. Kirkpatrick, and many other candidates whose chances of election ranked second to those of the candidates we have named. A large contingent of the Provincial Fellows came to town for the purpose of supporting one or other candidate, and the assembly of the College was, therefore, the largest which has come together for many years. The result of the election showed that the vigorous efforts of candidates were fully justified by the closeness of the contest. Of the outgoing Council, all the members were re-elected with the exception of Mr. Butcher, who was replaced by Dr. Quinan, Mr. Wilmot's being won by Dr. Hamilton, and Mr. Porter, the outgoing President, taking the Councillorship vacated by Mr. Walsh, who was chosen Vice-President.

One hundred and thirty-seven Fellows voted, and out of that large number only a single vote separated the two highest unsuccessful candidates and the two lowest successful competitors. We append the numbers for these gentlemen as declared by the President to the assembled College :—

Kirkpatrick	65
Wilde	69
Butcher	70

These candidates were unsuccessful.

Labatt and Quinan, a tie	72

Both elected.

The list of Council for the ensuing year stands as follows :—

President.—Rawdon Macnamara.

Vice-President.—Albert Walsh.

Secretary of the College.—William Colles.

Council.

William Hargrave.
Robert Adams.
James Barker.
William Colles.
Hans Irvine.
Hamilton Labatt.
Benjamin McDowel.
Edward Ledwich.
George H. Porter.
William Jameson.
Alexander Carte.
James H. Wharton.
George W. Hatchell.
Edward D. Mapother.
William A. Elliott.
Archibald H. Jacob.
John Morgan.
Edward Hamilton.
Edward J. Quinan.

Medical Qualifications in America.

THE *California Medicial Gazette* enters, in its last number, into a very vigorous protest against the sale of medical diplomas by *soi disant* Colleges and Universities in America, and appends the following list of licensing bodies and the number of persons who graduated in them :—

University of Pennsylvania . . .	130
Jefferson Medical College, Phila. . .	126
Massachusetts Medical College, Boston. .	58
College of Phys. and Sur. N.Y. . .	98
University Medical College, N.Y. . .	82
Bellevue Hosp. Med. College, N.Y. . .	124
Medical College of Ohio . . .	71
Miami Medical College, Cin. . . .	48
Cincinnati College of Medicine . . .	28
Buffalo Medical College . . .	34
Med. College of State of S. Carolina . .	14
Rush Medical College, Chicago . .	108
University of Louisville . . .	70
Med. Dep. Univ., Nashville . . .	17

Proceeding to comment on this list the *California Medical Gazette* says :—

"It would be interesting to the educated people of the United States, to know how many of the above 1,008 *Graduates of Medicine*, are what their title thould imply —educated gentlemen. How many are ignorant of the language in which medicines are written. How many whose knowledge of the English language is far below the requirements of our ordinary artisans. How many, in seeking a location to practice, will endeavour to secure one by such productions as the following, (which we received when about to leave a practice in the East), "Dear Doctor : I have just *herd* that you think of *leving* L——; you should *put* a good medical-man in your place. I would not go there in *opisition* to you, but wish you would introduce me if you *leve*."

So long as our Medical Colleges continue the present system of selling Medical Diplomas by the wholesale, so long will there be *Graduates of Medicine* who will depend upon cunning and knavery instead of professional skill—who will placard their names upon fences and rocks as the originators, discoverers, or authors of one or other potent mixture, one who is at all acquainted with the American system of medical education, knows that the possessor of an American Medical Diploma, *may be a scholar and a gentleman, or may be an ignorant knave.*

Says the *Medical and Surgical Reporter*, Philadelphia :—

> "Let us go into any of our first-class medical schools, the University, or the Jefferson of our own city, for instance. What do we find ? Perhaps more than one-half the young aspirants are ignorant of the language in which medicines are written ; besides many have a very meagre English education.
>
> "How can a profession be what it should, when any one can leave his cobbler's bench, quit his plow, or throw down his pick, because he conceives he can make money easier and faster by attending two courses of lectures in some college, and gull the people in practising the divine art of 'curing.'
>
> "So it appears to-day that there is such a spirit of rivalry in our schools—not so much which will turn out the best, but who will have the most graduates.
>
> "We are less sanguine about the efficacy of the reform in Ohio, when diplomas can be bought in this city for the price of a pair of boots. The apathy of medical faculties, and medical societies, will only be broken when they see year by year the public growing more and more disgusted with the ignorance and petty jealousies that now prevent the usefulness of our art to so great an extent."

The present system of medical education is the mother of Quackery, and those who possess a diploma from the same university, should not mock each other with that old taunt "I'm holier than thou." But under the present system of granting diplomas, medical graduates cannot form a united body.

Cholera in India.

CHOLERA is raging at Baroda ; and all intercourse between the city and the camp has been prohibited. The natives have hung strings of cocoanuts and leaves across the streets, believing that these will prevent the spread of the epidemic.

The disease has also broken out amongst the troops at Kamptree and Mhow.

The East India Railway has supplied every station master on their lines from Calcutta to Delhi, with cholera pills accompanied by short directions for the treatment of the disease. These medicines are intended not only for the benefit of their own servants, but also for passengers or any one who may apply for them. We may also mention that, if any case of cholera should occur among passengers, the carriage in which it has occurred is not again used until it has been thoroughly fumigated and washed or painted.

The Economy of Ventilation.

THE financial gain which may result from an outlay on fresh air, is very forcibly illustrated by a recent communication of General Morin to the Academy of Sciences, Paris.

General Morin communicated some curious facts resulting from the good ventilation of a large cloth factory at Orival near Lisieux. The looms are set up in a large hall measuring 61 metres by 33, but only three metres and a third in height. Each weaver has a space of five square metres and a third allotted to him, and the net capacity of the hall is about 6,000 cubic metres, thus allowing each person only 15. The factory is not warmed in winter. The great number of hands, the necessity of keeping the cloth on the loom in a sufficient state of moisture, the emanations of the gas burners, and want of regular ventilation, rendered the place so pestiferous that the number of hands on the sick list was generally between 30 and 40. Moreover, the work was often interrupted, because of the necessity of allowing the workmen to go out now and then, in order to breathe a little fresh air. They had lost all their appetite, and were consequently weak and slow at their work. The master of the establishment, M. Fournet, at length resolved last year to lay out a sum of 15,000f. for the purpose of introducing a good system of ventilation. The tall chimney of the engine-room was so arranged as to draw off the vitiated air, and orifices for the introduction of new were opened in the ceiling, with contrivances for regulating the quantity. In this way a permanent supply of about 14,000 cubic metres of fresh air per hour was obtained, and the results observed in the course of the ten months the system has been in operation are really astounding. Instead of the ten or twelve men per day obliged to leave off work on account of illness, the sick-list is now reduced to three or four a day, so that there is a gain of nearly 2,400 days a year that were previously lost both to the establishment and the workmen, who, in the aggregate, thereby profit to the amount of about 5,000f. per annum, both in wages and saving in medicines.

Mortality in India.

FROM a comparative statement of the mortality in the North-West Provinces of India, during the month of March 1868 and March 1869, published in the *Government Gazette* N. W. P., we learn that the death-rate was alarmingly high in that month this year as compared with 1868. The total number of deaths in the North-West Provinces in March last year was 23,527, while in the same month this year the death-rate has risen to 35,770, or a percentage of deaths to the population of ·12, as compared with ·7 last year. Of the total deaths, there were 1,572 from small-pox in 1868, and 16,067 this year; from cholera there were 797 deaths in 1868 and 1,283 in March last; from fever, 14,560 in 1868 and 11,892 this year; while from other diseases the numbers were nearly equal, 6,598 in 1868 and 6,528 in March last.

Effect of the Suez Canal on Climate.

IF we are to believe M. Rayet the climate of the Isthmus of Suez will undergo a transformation in consequence of the arrival of the sea in Lake Timsah and in the basin of the Bitter Lakes, and the creation of two immense sheets of water in a region where there existed nothing but marsh land occasionally inundated by the Nile.

This modification of climate has already become observable. According to the evidence of persons, who had resided on the spot as old *employés* of the Suez Company, the rains are much more frequent than they were five or six years since. *Apropos* of this report M. Buys-Ballot has addressed to the Academy of Sciences of Paris the conclusions of a work published some time since, in which he has shown that the drying of the sea at Harleim has modified the climatic condition of the country. The result of numerous investigations is, that since the drying of these 19,000 hectares the temperature has risen half a degree in summer, and has fallen half a degree in winter.

Heart Disease and the Turkish Bath.

ANOTHER death has taken place in the Turkish bath at Cork, and it has again raised the question as to how far it is secure or judicious for cardiac patients to undergo the violent variations of temperature which the bath involves. It appeared from the evidence that for the previous week the deceased's appetite had somewhat fallen away and he was not in strong health, though he did not complain. He went to the bath between seven and eight o'clock, was there about three-quarters of an hour, there being other persons in the same room (the sudatorium, or intermediate apartment) at the time. Deceased was on a couch when it was noticed that he breathed heavily, and that he was in a fainting state. Assistance was called and the deceased was removed at once to the outer or cooling room, and restoratives were applied. Dr. Shinkwin was sent for and came immediately, but the deceased had expired before his arrival. In the doctor's opinion (without having made a *post-mortem* examination) the deceased was a man of weak heart and had died from syncope. In reply to the Coroner, Dr. Shinkwin gave it as his opinion that the Turkish Bath was not fit for a person in deceased's condition—with a weak heart. Dr. Barter gave it as his opinion that the bath was beneficial for persons with weak hearts, and said he had several patients in that condition at his establishment at Blarney who took the bath twice a day with manifest advantage. The jury returned a verdict to the following effect:—"That death was caused, as they believed, by syncope, his illness lasting about an hour; and that every attention was paid to the deceased while at the bath."

It was obviously not the function of the jury to declare whether or not persons suffering from heart disease might safely take the bath, but it is nevertheless a question which must be answered by those who say that they may. Without pledging ourselves to a verdict, we must say that the feeling of the profession is greatly against the use of the bath by such persons, and all our present knowledge on the subject is against subjecting them to the danger.

It is, indeed, a great responsibility for those who advise the use of the bath, and it would be well if they could place before the profession some of the arguments which they consider justify them in giving the advice.

The Dublin Poisoning Case.

THE distrust which is created in the public mind is not the least important result of a misfortune such as the accidental poisoning of Mr. Guinness last week, and the feeling is widely expressed that such an occurrence should be, if not impossible, at least in the highest degree improbable.

We recapitulate the facts. Mr. Guinness had been taking a tonic mixture with carbonate of ammonia, and it appears that he remarked that his medicine had not the usual appearance. He refrained from taking it, and went back to the establishment from whence it had come for the purpose of having it changed. He took the medicine afterwards, and died within twenty minutes from the effects of cyanide of potassium, with which it had been compounded in mistake.

It is hard to suppose that the business of a large establishment, such as Messrs. Hamilton, Oldham, and Long can be transacted from year's end to year's end without a single error, and if the public were satisfied that every precaution against mistake was taken we feel convinced that they would pass no hasty judgment on the general management of the establishment in which the error might occur, but, if the newspaper reports be correct, there were circumstances in the case of Mr. Guinness to call for special note. It was sworn in evidence that the stock bottles of the Grafton street house were sent to Sackville street to be replenished, which was done by the storekeeper, who, it appears, was "apparently a boy of 17 years of age," and who admitted that he had filled the carbonate of ammonia bottles from a jar which had no label. If this be true, without doubt the verdict of censure passed by the jury was justified, for it is utterly reprehensible that duties of such vital importance should be confided to any but a staid, experienced, and careful man.

Cyanide of potassium, though it superficially resembles carbonate of ammonia, is distinguishable from it by the merest glance. The poison is in white opaque slabs, without smell, the tonic is in crystalline lumps, with a powerful ammoniacal odour. It would seem to be difficult to fail to distinguish between them if care were exercised, and until the apparent neglect be explained the verdict of the jury must bear the colour of being a just one.

Female Medical Education.

THE profession will be interested to learn how female medical education has fared since last year, and for their information we quote some of the facts and figures set forth in the annual report presented to the Female Medical Society last week.

"There have been twelve entries of new students. Two more of the senior students have passed the preliminary examination in Arts at Apothecaries' Hall. The total number of ladies who have entered as students during the five years is eighty-one; of these forty-three were single, twenty-two married and sixteen widowed. Some of these ladies have attended the lectures merely as a means of intellectual culture. Several were relatives of clergymen, seventeen were relatives of medical men, ten were midwives previously in practice, two were hospital matrons, three were superior nurses, one an artist, four wives, widows, or daughters of chemists, one was prepared to act as medical missionary to India in connection with the Society for the Propagation of the Gospel; a considerable number were or would have been governesses, and some had been previously of no occupation.

"The receipts for students' fees during the last session have not quite equalled the disbursement in lecturers' fees."

Our readers have from time to time been put *au courant* with the progress of the courtship of the Female Medical Society, and the British Lying in Hospital, and with the circumstances under which Dr Eastlake was extruded from the physiciancy of the latter institution, and the pugilistic encounter which formed the last scene of the drama.

The committee put their version of the proceedings in the following terms, which of course our readers will accept *quantum valeat*.

In the last report the committee announced that a co-operative alliance had been effected between the British Lying-in Hospital and the Female Medical Society, on the basis, that the Society's friends would help in the support of management of the Hospital, while its instructed students would attend to its patients gratuitously within the Hospital and half a mile radius therefrom; on the other hand, the Hospital arrangements for teaching practical midwifery were to be raised to a level with the theoretical and scientific teaching at the College. This arrangement was in operation for twelve months.

In consequence of a series of proceedings amounting to a conspiracy which no parliamentary language would describe, and in the course of which the most malignant calumnies were invented and circulated against Dr. Edmunds and other supporters of the Female Medical Society, the Committee was obliged to terminate the alliance abruptly on April 22, 1869, by passing the following resolution—

"That the Committee of the Female Medical Society, in view of the various false statements which were made in reference to the College at the late meeting held in the Freemason's Tavern, feel it right in the interests of their students, at once to terminate the alliance between the Institution, and request their Honorary Secretary to notify this resolution to the Board of Management of the British Lying-in Hospital."

St. George's Hospital.

THIS great charity will no doubt be much aided by the late public meeting and the powerful advocacy of the *Times*. None is more deserving. We are happy to see the first fruits of this appeal, in a donation of one thousand shillings, which the donor promises to convert into guineas by sending £1,000, provided £45,000 are raised by the 15th of July. Surely, within a radius of a mile, there are more than forty-five persons who can well afford out of their abundance to be equally generous. It will be a standing reproach to the wealth of the West end of the Metropolis, if the challenge thus made is not responded to.

Mr. Morant Baker takes the Lectureship on Physiology at St. Bartholomew's Hospital.

Liebig is to have the Albert Medal of the Society of Arts.

Mr. Nunneley is to preside at the College of Surgeon's dinner.

The annual dinner of the Metropolitan Free Hospital takes place to-morrow.

H.R.H. **Prince Arthur** will be present at University College Hospital dinner, 23rd June.

The German Hospital Bazaar produced more than £3,000.

A **committee** is about to assemble for the purpose of inquiring into the causes and effects of the sickness at present prevailing in Bangalore, where cases of small-pox, diphtheria and typhoid fever are rife.

It has been ascertained by experiments that the Cinchona plant may be as successfully cultivated on the hill slopes of British Burmah as at Darjeeling and on the Neilgherries.

Professor Pietro Cipriani, of Italian celebrity, who has been dangerously ill with an enormous anthrax on the back of his neck, is, we learn with pleasure, much better, and has retired to the country to recruit his health.

The Cattle Plague is making dreadful ravages in Austria. The herds in Gallicia are decimated by the disease, which has been introduced by animals imported from Russia. The plague has been unfortunately extending its limits far and wide, and has reached Hungary, where the rearing and fattening of stock is carried on on a great scale.

Her Majesty's Consul at Jeddah has reported that, though the concourse of pilgrims at Mecca this year has greatly exceeded last year's numbers, their health has been in all respects good, and the proceedings have terminated satisfactorily.

We regret to learn from the *Pioneer* that cholera has re-appeared in H.M.'s 58th Regiment, at Allahabad, both in the wing occupying the Chatham Lines, and in that which lately returned to the New Barracks. The *Englishman* remarks that "the matter deserves the more attention as there is no epidemic in the city, and the men employed in the railway works are healthy."

"**We** only a short time back," writes the *Lucknow Times*, "announced the appearance of cholera in H.M.'s 1-11th Regiment, at Fyzabad, and now we regret to have to record its presence in the ranks of the Rifles at Seetapore, and in such a serious type as to have caused great alarm to the military authorities. We sincerely trust every exertion will be made to check the spreading of this dreadful disease."

By the will of the late Mr. T. Brown, of the firm of Longmans and Co., the well-known medical and scientific publishers, whose personalty was proved under £140,000, Christ's Hospital becomes possessed of £10,000. St. George's Hospital, Royal Free, St. Bartholomew's, St. Mary's and the Cancer Hospitals, each £500, free of legacy duty.

The crew of her Majesty's screw sloop Camelon are said to be suffering from epidemic small-pox. The men have been landed at Panama, whence they have proceed to Morro Island during the disinfection of their ship.

With the sanction of the Secretary of State for India, it has been notified that leave to the extent of eighteen months taken in consequence of wounds received in action, or of sickness contracted on field service, shall be allowed to count as service towards pension in the case of officers of the British Army who entered the Indian Staff Corps on or soon after their first formation, though such leave may have been taken before their admission to the Staff Corps, but subsequent to the publication of G. G. O. No. 1,113 of 1st September, 1857. The leave will be allowed to count as service in the same way and on the same conditions only as it is allowed to reckon in the case of officers of the Indian Army.

◆

SCOTLAND.

DEATH OF BRUCE BARCLAY, M.D.

Our fellow-citizens of all grades and shades of opinion will, we feel assured, cordially unite with us in tendering the venerable Principal of the University our sincerest sympathy in the heavy affliction he has just sustained in the loss of his eldest son. On Tuesday forenoon, after an illness of only a few weeks, resulting from a cold caught, it is stated, in New York, Dr. Bruce Barclay died in his father's residence within the College. He had been for several years professionally engaged in the Chinese Seas, but his health giving way to some extent he returned home. Preferring sea life to settlement on shore, he engaged with Messrs. Handyside and Henderson to act as medical officer on board of one of their Transatlantic Line, and in this capacity has been for several years usefully employed. Our readers will remember that he was one of the saved in the boat of Capt. Munro when the Hibernia was lost; and on the appointment of Mr. Munro to the command of the new steam-ship India, Dr. Barclay accompanied his friend as surgeon in the two first voyages of that steamer to New York. Dr. Barclay was a gentleman of varied accomplishments—of frank and agreeable manners, and was held in great regard by all with whom, professionally or otherwise, he came in contact. —*Citizen*.

THE SCOTTISH REGISTRAR-GENERAL'S MONTHLY RETURN.

The monthly return of the births, deaths, and marriages registered in the eight principal towns of Scotland, with the causes of death at four periods of life, for May 1869, was issued last week:—

During the month of May 1869, there were registered in Scotland the births of 3,297 children, of whom 1,685 were males and 1,612 females. Of these, 2,999 were legitimate and 298 illegitimate; being in the proportion of one illegitimate in every eleven births, or nine per cent. of the births illegitimate.

In Leith, 2·2 per cent. of the births were illegitimate; in Greenock, 3·2.; in Paisley, 3·3; in Glasgow, 8·8; in Perth, 9·3; in Edinburgh, 9·5; in Aberdeen, 10·5; and in Dundee, 14·3 per cent. During the month 456 marriages were registered in the eight towns. Increase of population being allowed for, this number is twelve in excess of the May average of the previous ten years. The deaths of 2,662 persons were registered in the eight towns during May, of whom 1,334 were males and 1,328 females. This is the greatest number registered in any month of May since the Act came into operation; and allowance being made for increase of population, it is 329 deaths above the average of the month for the last ten years. Of the 2,662 deaths registered, 1,224, or 46 per cent. were of children under five years of age. In Perth, 19 per cent. of the persons who died were under five years of age; in Aberdeen, 26; in Dundee, 41; in Edinburgh, 43; in Paisley, 47; in Greenock, 48; in Glasgow, 49; and in Leith, 58 per cent. The zymotic (epidemic and contagious) class of diseases proved fatal to 653 persons, thus constituting 24 per cent. of the mortality in the eight towns. The rate was slightly exceeded in Glasgow from the prevalence of measles and fever, and greatly in Leith from that of measles. Fevers caused 164 deaths, constituting 6·1 per cent. of the mortality. Of these 164 deaths, 127 were attributed to typhus, 32 to enteric, 1 to relapsing, 2 to simple continued, and 2 to infantile remittent fever. The next most fatal of the epidemics was measles, which caused 138 deaths, or 5·2 per cent, of the mortality. In Leith, 18·3 per cent. of the deaths were from that cause. Hooping-Cough caused 122 deaths, scarlatina 108, diarrhœa 36, croup 29, diphtheria 13, small-pox 6, metria 4, dysentery 8, and cholera 2. To apoplexy were ascribed 52 deaths, to paralysis 48, to diseases of the heart 80, to hydrocephalus 77, and to premature birth debility 119. The deaths from inflammatory affections of the respiratory organs (not including consumption, hooping-cough, or croup) amounted to 535, or 20 per cent. of the whole mortality. Those from consumption alone numbered 391, or 15 per cent. of the mortality of the eight towns. 56 deaths were from violent causes, 3 of which were suicides, and 2 murders. A boy, 5 years of age, was poisoned by eating a decayed turnip. 4 deaths were caused by intemperance, and 3 by delirium tremens. 3 males and 5 females had passed their 90th year, the eldest being a widow of a currier, and aged 96 years.

Mr. Symes' health is said to be improving, and the *Lancet* of last Saturday contained a communication from him, dated June 1st.

The Edinburgh Infirmary Bill will not be proceeded with this year.

On leaving Ayr to enter into practice at Glasgow, Dr. Burns was entertained at a dinner, and presented with a handsome tea and coffee service.

Correspondence.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MR. EDWIN HEARNE ON THE COMING ELECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the name of the Provincial Fellows and Members of the Royal College of Surgeons of England, I most heartily thank you for your spirited, almost single-handed, defence of their hitherto much neglected interests; and I have an additional pleasure in doing so, because, in suggesting the instrumentality for accomplishing an important object—that of protecting the rights of the hard worked surgeons of England and Wales—you have in no degree infringed the legitimate claims of any other class.

Taking as a basis the population of London and their surgical requirements, the representation of general practitioners in the College of Surgeons should be in about the proportion of one London Councillor to six provincial; whilst the actual representation is one provincial to eight London surgeons. Now, provided that the character of our surgical legislation were in any degree satisfactory, I would refrain from inquiring whether our legislators resided in the provinces or in the metropolis; but unfortunately our legislation can only be regarded by unprejudiced thinkers as unsatisfactory in the extreme, for although confessions of faith have been plentiful enough since the now distant period when many of us took an active part, and made considerable sacrifices, in aiding to break down routine by securing the return to the Council of the College of Sir Wm. Fergusson, where has been the actual gain? Next to *nil*. Therefore, I contend with you that our system requires a complete revision. It is at present little other than deception from beginning to end.

Unnecessary difficulties—formalities, obstructions, and expenses—have to be contended with even in barely nominating a member of the Council, and, what is worse, a strictly honest candidate can scarcely subject himself to rigid criticism in reference to the declaration required of him in order to obtain a Councillor's seat; for instance, the candidate is required to make the statement "that he is in the *bonâ fide practice* of a surgeon." Now, a considerable proportion of the practice done by Liston, Sir B. Brodie, and Sir A. Cooper, was other than surgical; and it is well known by the profession that even less than at the periods referred to do our well educated surgeons confine their attention, and actual engagements, to the "*bonâ fide* practice of surgery!"

Too many of our so-called heads of the profession have been ever ready to swallow everything required of them in order to secure posts of trust and honour, but they have generally enumerated their broad principles so *indefinitely* that when afterwards taunted with tergiversation and apostasy, they have been able to excuse themselves with the plea that we, their constituents, ever misunderstood their intentions. Such men now occupy, temporarily, seats at the Council Board to the enormous detriment of our best interests. Mistakes having been thus unfortunately made, let us hope that the Fellows are prepared to guard against like disasters in the future by requiring from every member of our profession, who aspires to the honour of filling a seat in the Council of the Royal College of Surgeons of England, such a well-defined confession of the minimum of reforms he is prepared to advocate with all the energy he can command, that there shall be never more a misunderstanding on that question. But it may be well to summarise briefly what, in the opinion of many independent Fellows of the College, should be *the smallest measure of reform* expected of all candidates for our suffrages.

We believe that the thorough efficiency of examinations is essential to the welfare both of the public and the profession, and that every proposition calculated to secure that object should be strenuously supported.

Election by seniority, election of the examiners by the Council from the Council itself, the assignment of several different subjects to the same examiners, indefensible in argument and injurious in practice, are most serious obstacles to the improvement of examinations; therefore, all examinerships should be thrown open to competition, separate examiners should be appointed for each subject, examiners should hold office for a limited period, and Councillors should be disqualified for acting as examiners so long as they continue in office.

Vested expectations could be satisfied by allowing the present members of the Council to be elected to examinerships on the condition that their election should be followed by immediate retirement from the Council.

The fellows of the English College of Surgeons have less control over the executive than those of any other medical corporation; and regarding this as a hindrance to progress, the number of retiring Councillors (annually) might be fairly increased from *three* to *six*.

The right of voting for the representation of the College in the Medical Council should be conferred at once on all *members* and *fellows of the College*.

The clause in the Charter which requires that *fellows* of the College should have a standing of *fourteen*, and *members* of *twenty*, years before they become eligible for a seat in the Council, should be repealed with the least possible delay.

The fellows and members should not only be admitted, but in every possible way encouraged, to attend the debates of the Council, and thus obtain the opportunity of informing themselves how each Councillor had voted and fulfilled his trust.

The provincial fellows of the College are virtually fined for the exercise of their voting privileges. Regarding this as unfair, and as destructive of an interest in the affairs of the College which ought to be encouraged rather than repressed, the use of voting papers at all elections should be permitted, just as they are used at the Universities in the election of their representatives in Parliament.

The retrospective legislation of 1843 should be so modified as to place on an equality all the members of the College, who were legally equal prior to the granting of that obnoxious Charter; for it is never too late to remedy an unquestionable injustice.

In regard to subjects of a more general character: the establishment of a simple qualification in all the departments of professional practice in place of the numerous qualifications, varying in value and extent, which now exist in the United Kingdom, is a question of paramount importance; but to attain this object two things are at least necessary—first, to arm the Medical Council with absolute authority over the medical examinations; and secondly, to make the Council thoroughly representative of all classes of interests in the medical profession.

In conclusion, permit me to add that I shall continue ever ready, at every available opportunity, to aid the cause of progress, in whatever aspect presented, to the extent of my limited power.

Believe me, dear Sir,

Yours faithfully,

EDWIN HEARNE, M.B. Lond., F.R.C.S. Eng.

Southampton, June 5, 1869.

MR. SOLLY'S CANDIDATURE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you do me the favour to publish the enclosed correspondence.

I am sir,

Yours obediently,

SAMUEL SOLLY.

6 Savile row, June 7th, 1869.

DEAR SIR,—Is it your intention, as a returning member of the Council of the Royal College of Surgeons, to seek re-election in July next, and if so, are you prepared to support the following reforms in the College, viz:—

1st.—The right of reporters to be at the meetings of the Council.

2nd.—The removal of the remaining objectionable restrictions which prevent fellows being members of the Council.

3rd.—The power for fellows to summon by requisition a meeting of fellows and members at the College, for the purpose of discussing matters of public policy in connection with the institution.

4th.—The election of a representative in the "General Council" by the fellows and members.

5th.—The selection of Members of the Court of Examiners from amongst the fellows and members generally, and not exclusively from the Council.

Your reply, which is awaited with a considerable degree of anxiety, will be made public for the information of the fellows and members generally.

I remain,

Dear Sir,

Yours respectfully,

(Signed) EDWIN MORRIS.

Spalding, May 26th, 1869.

DEAR SIR,—In reply to yours of yesterday, I must at once decline pledging myself, if re-elected on the Council of the College of Surgeons to support any particular measures, however much I may agree with the spirit of them.

If my general conduct as a surgeon, if what I have done for the advancement of anatomy, physiology, and the practice of surgery, coupled with the fact that I have always been a reformer will not secure my re-election, I must submit to the blow.

Nevertheless, I do feel very confident that the great body of fellows will act justly, and that I must only ask every fellow who thinks that I am deserving of the honour of re-election, to attend the meeting on the 1st of July.

Believe me to remain,

Yours truly,

SAMUEL SOLLY.

Vice-President of the College.

6 Savile row, May 27th, 1869.

MR. ERICHSEN'S CANDIDATURE.

Mr. Pollock presents his compliments to the Editor of the MEDICAL PRESS AND CIRCULAR, and will feel obliged by the publication of the enclosed correspondence.

DEAR SIR,—Mr. Erichsen will stand for election into the Council of the College of Surgeons on 1st July, his friends are anxious both on public grounds and from personal regard, that he should be elected.

His seniority among the Fellows, and professional position, would give him a just expectation of being elected were not exertions being made to secure the election of other candidates, and Mr. Erichsen may thus be passed by if his friends do not support him.

With regard to his political opinions, I am sure I need not inform you that Mr. Erichsen is anxious to open the management of the College to all the Fellows, to remodel the Court of Examiners, and to introduce voting by proxy.

Mr. Erichsen will put a full statement of his views into the Medical Journals.* I shall be very glad if you can be present at the election on 1st July at two p.m.

Very faithfully yours,

(Signed) BERKELEY HILL.

To Geo. D. Pollock, Esq.

14, Weymouth street, London, W., June, 1869.

DEAR SIR,—I beg to acknowledge the receipt of your letter, in which you ask me to be present at the College of Surgeons on the 1st July, that I may support Mr. Erichsen, one of the candidates of the Council.

Though personally unacquainted with you, your letter is of so much importance, that I think it right in the interests of the Council and of the Profession to reply to it. And I trust you will consider all I say in reference to its contents as arising simply from a sincere wish to uphold our professional status.

I greatly deplore the step you have taken; that you consider it requisite and right to canvass the Fellows of the College on behalf of Mr. Erichsen.

Mr. Erichsen is well known to the profession. If his character and position are not of sufficient worth to insure his election, without the aid of canvassers seeking to seat him there, he should not sit in the Council. If his character and position are not as I take them to be, the steps you have had recourse to are derogatory to his cause. He surely wants not your certificate of character to place him there. Then, it were better your letter had been left unwritten.

I look upon it as lamentable that any surgeon of his position should be compelled to submit to a condition, such as your letter would indicate it necessary to insure his election to the Council. The sooner it is put an end to the better; and it is with some hope that canvassing may be for ever denounced and stopped, that I have taken advantage of your letter to put forward my views on the subject—views, which I am satisfied are highly entertained by the leading surgeons of the day. I think the whole proceeding wrong, unprofessional and degrading.

---

* We had not received this statement at the time of going to press, —ED. M. P. and C.

Besides, I may observe, that in your writing to ask for my vote, you have entirely overlooked the fact that I am quite as able to judge as yourself, whether Mr. Erichsen is the right man to take his seat in the Council. I have known him professionally longer than you can have done; and I cannot help thinking that you are quite wrong in supposing one of Mr. Erischen's position in the profession requires the aid of your public solicitation of votes to secure his election.

I beg in conclusion to say that it is my intention to send the correspondence to the Medical Journals for publication.

I am, dear sir,
Yours faithfully,
To Berkeley Hill, Esq. GEORGE POLLOCK.
36, Grosvenor street, W., 7th June, 1869.

MR. HENRY LEE'S CANDIDATURE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In olden times, when two distinct companies of surgeons existed, one company called the Barbers of London, and the other the Surgeons of London, it was very fit and proper that his Majesty should will, ordain, constitute and declare, give and grant certain privileges to particular individual members of those companies.

It was at that time His Majesty's further will and pleasure that the individuals whom he had named should elect, choose, and appoint twenty-one persons to be the Court of *Assistants* of the same College. Of these Assistants, ten were to be appointed Examiners. His Majesty further willed that the Masters, Governors and Assistants should in July of each year choose out of the Examiners one person to be Principal Master, and should choose the requisite number out of their own body to be Examiners of the said College; and also choose out of the members of the College certain persons to supply any deficiency there might be in the Court of Assistants.

The Examiners soon became the controllers of the College, and instead of being Assistants they became the real Governors. It was they who determined who should be admitted into the Council, and they naturally took care to admit those only who would conform to their principles. Nothing could work in a more vicious circle than things then did. The Examiners elected the Council, the Council elected the Examiners; a Councillor might then, and may now, give the casting vote in his own favour as an Examiner. The Council, practically under the control of the Board of Examiners, now had the exclusive appropriation of large sums of money. These sums were derived almost entirely from junior members of the profession, and yet they were allowed no voice either in the appropriation of these funds, or in the management of the College.

Circumstances having so far changed from the time when our charters of incorporation were granted, a change was called for in the government of the College.

Whenever any society or corporation shows that it has the elements of self-government no length of time can elapse before it attains its freedom. The College of Surgeons has shown that it has that power and has obtained the right to exercise it. Much has been accomplished but more remains to be done. We are in a transition state. By far the greater number of our body as yet have no voice in the management of its affairs. if they prove themselves (as I doubt not for a moment that they will) capable of discussing and voting upon principle, independent of personal or private interests, they must ere long have their share in the management of the affairs of our College. I should be glad even now to see every subject of interest submitted, at periodical meetings, to the discussion of the Fellows and Members of the College; and whenever such a subject could be placed in a definite form, I think that the country Fellows should be allowed to vote upon it by proxy.

The privilege of voting has also its responsibilities; any abuse of these presents a direct hindrance to self-government. This subject has been brought vividly before my mind in the mode of election of Councillors of the College.

It appears to me evident that a gentleman who seeks the honour of a seat in the Council, and those who support him should have the interests of the Profession alone in view. If either directly or indirectly they add to the burdens, already great, of that profession, they so far do an injury to their professional brethren. Now, those who have instituted the practice of canvassing at election for the Council have evidently done this. They have instituted a very troublesome and distasteful ordeal, which they call upon all future candidates for a seat in the Council to go through. I wish, as far as I am able, to put it to the profession whether this shall be continued.

In former years, we have seen active young Fellows freely discussing the characters of their seniors; and canvassing within the walls of the College itself for some particular person, in opposition to others, quite independent of any principle; and now we have a junior Fellow openly requesting, even those who do not know him, to vote for one of his colleagues in preference to another. It would be idle to think that any Fellow of the College must not see that what he does for one may be against another. Such services must be paid either in malt or in meal, or through some more refined medium. They can have nothing to do with the interests of the profession. Indeed, any one who has time to spend either upon a personal canvass, or upon repaying in kind, those who canvass for him has, necessarily, less time to spend upon his own legitimate work or upon the affairs of the College.

It may be said that canvassing is allowed in other constituencies, and, therefore, it is proper in ours. The cases are not parallel; other candidates came before people with different views and interests. We are a scientific society and have common objects in view. The interest of our profession is, or ought to be, one. Any person who breaks up that interest, or who unnecessarily excites divisions, is doing a real injury to the profession. Any one who might seek to obtain an office in the College of Physicians by canvassing, would, by that act, be disqualified from holding the office; and it hardly becomes the Fellows of the College of Surgeons to assume a less dignified position.

Practically, the evil results of the system of canvassing are but too apparent. We have seen members of the Council, rather than engage in what they considered an unprofessional and a degrading contest, resign their seats; some of the most distinguished Fellows of the College have declined to be placed in nomination under the present system; and some, after they have been put in nomination, have declined to canvass, or to allow others to canvass for them; and if all the members of the Council had been true to the dignified position which they hold, canvassing, with its many vexations, heartburnings, and consequent and subsequent bitter reminiscences, would have been discountenanced long ago. There are men who do not seek a seat in the Council for any private advantage of their own; who would, if need be, forego, and who have foregone, that honour, rather than purchase it at the expense of what they might think any unfair advantage; and there are now in the ranks of our profession, according to the words of the old song, Fellows "forty good as they."

The future of the College is now fairly in the hands of the Fellows. The increase of the franchise will naturally depend upon the way in which it is used. If Fellows vote in accordance with some principle independent of any private consideration, they lay the foundation of a good government for themselves and their successors. If, on the contrary, each one were to vote in accordance with some private end, it would be evident that we have not within ourselves the elements of good government. It would, under such circumstances, only increase the confusion of an election, to extend the power of voting to greater numbers.

Something similar may be said with regard to candidates. A candidate should represent certain principles, but, if a candidate depend for support upon the private solicitation of his friends, he can represent no principle. He will be called upon, by each class of his supporters, to vote in a different way; and these supporters themselves may, probably, after a few years, when they find themselves placed in different circumstances, alter their opinions.

I trust that the Fellows will show in future that they have within themselves the power of self-government, and that they will exercise that power for the good of the profession.

This will be the surest, most legitimate, and most powerful mode of enfranchising their professional brethren.

I am, &c.,
9 Savile Row, June 7, 1869. HENRY LEE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It has long been a puzzle to medical investigators to discover of what peculiar changes the blood is the subject in the numerous diseases, of which some alteration in the vital fluid is admittedly the cause. That the blood does undergo some very profound change in such a disease as small-pox or scarlatina, or any of the other exanthems, is granted, I believe, by all who have given any attention to the subject, because, on no other supposition can a satisfactory, or nearly satisfactory explanation of the various phenomena attendant on these diseases be given.

In speaking of *changes* in the blood, I must not be understood as referring to those grosser changes, such as differences in the relative amount of red and white globules, in the proportions of globules to serum, of serum to salts, &c., which occurring as they do in so many diseases, have been ably investigated, and with very important results, by a host of modern scientific physicians. The changes to which I allude are of a more subtle character, and should, I believe, be designated as "molecular;" changes which have hitherto eluded the researches of the ablest microscopists and chemists, changes which have never been *directly* observed, but which, from the observation of symptoms to which they are supposed to give origin, are admitted to have taken place. To make my meaning clear, take the case of syphilis. Here is a disease contracted by infection, and at first of a limited and simply local character, after a time, however, the blood, as we presume, becomes vitiated by absorption from the local disease, and this deterioration of the quality of the blood may be manifested by characteristic disease of many of the tissues of the body. Now theorists will tell us that the disease, which at first was a local one, became general by reason of a kind of fermentation set up in the blood, by which the specific virus of the disease was multiplied, and that to such a degree, as to poison the whole current of the circulation, in fact, they say that, just as the presence of a minute quantity of a *ferment*, under certain conditions, in a solution of a ternary compound of feeble stability is sufficient to induce the decomposition, and alter the character of the whole solution, so the small quantity of virus absorbed from the local disease affects the entire blood. But, let us see how far we can investigate the changes in the two cases. In the former we can determine exactly the changes produced, and almost step by step, we can measure, for instance, in the case of a solution of sugar into which has been introduced a little yeast, how much carbon dioxide has been given off, and how much alcohol, water, and yeast remain, but inoculate a man with syphilis, and when the "fermentation" has probably reached the stage of completion, draw an ounce or so of blood from a vein, examine it microscopically, and by reagents, and what changes in its composition will you observe? In the case of an otherwise healthy man, probably none whatever the blood is apparently as healthy as any blood could be. Nevertheless, we consider it, and probably with justice, diseased. In like manner, examine by any, or all of the *usual* modes of investigation, the blood of a person who has had small-pox. Do you observe any change? None. Yet it is generally agreed that the blood has undergone a profound change, of such a character, that the recurrence of the disease in after-life is prohibited.

Now, the foregoing observations are intended to demonstrate, the undoubted necessity that exists for the employment of a more refined method of analysis than any which has hitherto been in use by medical observers.

The very extraordinary and beautiful results arrived at by Kirchhoff, Bunsen, Mr. Crookes, and other eminent chemists, suggest to my mind the feasibility of employing spectrum analysis, as a means of determining the nature of those molecular changes which the blood probably undergoes in several disease processes, or at least of demonstrating that some such alterations do occur. The analysis might be more a relative than an absolute one, that is to say, the spectrum of the blood of an average healthy man being determined, we might compare with it the spectra of specimens of blood taken from the subjects of disease and mayhap discover some constant peculiarities in the latter which might furnish an unerring basis for diagnosis.

If such a suggestion has not been previously put forward, I hope the forgoing remarks may be the means of inducing some intelligent medical observer, who really loves his profession, and has time and resources at his command, to prosecute those enquiries and perhaps to illumine with a flood of (dispersed) light those minute changes hitherto veiled in impenetrable obscurity. For the present, I will leave the subject, but, were it not that it would be trespassing too freely on your columns, it would be easy to indicate the immense benefit which would accrue to various branches of medical science, by even a limited success of such an enquiry.

J. R. McMAHON MURPHY, A.B.,

◆

THE DEBATE AT THE DUBLIN OBSTETRICAL SOCIETY.

WE are requested to publish the following letters:—

1 Upper Merrion street, June 11, 1868.

DEAR DR. KIDD,—Three weeks have elapsed, and no proof of the adjourned debates on my paper on Zymotic Disease has reached me since Dr. Denham's.

I am therefore left unsupplied with the strictures that have been made at the last three meetings, upon which I am to frame my reply.

Pray, what is the reason of this?

In order to prevent the professional public, interested in this discussion, ascribing the further delay, that must now necessarily occur, to any hesitation on my part in preparing and furnishing my rejoinder, I think it due to them, as well as to myself, to send a copy of this note to the MEDICAL PRESS AND CIRCULAR for insertion,

And remain,
Yours very faithfully,
EVORY KENNEDY.

17 Merrion square East, June 11, 1869.

MY DEAR SIR,—In reply to your letter of this date, in which you ask why you have not yet been furnished with the reports of the latter portions of the debate at the Obstetrical Society on your paper on Zymotic Diseases, I beg to say that, as quickly as the reports reached me, I placed them in the printer's hands, and directed him to use all possible expedition in getting them printed, but the only one that has yet reached me is Dr. Beatty's, a copy of which I send you herewith.

I also got the first proofs of Dr. Sawyer's and Dr. H. Kennedy's papers yesterday, and have sent them to the authors for correction; these I shall send to you the moment they are ready.

At the last meeting of the Society it was resolved to allow you to name the next night of meeting, and when I send you the reports I shall ask you to let me know for what evening I shall call a meeting to hear your reply.

I am, yours truly,
GEORGE H. KIDD.

To E. Kennedy, Esq., M.D.

Medical Gleanings.

PENETRATING WOUND OF ABDOMEN.—HERNIA OF A PORTION OF THE SPLEEN.—RECOVERY.

IN connection with some remarks upon the functions of the spleen, Dr. G. Bouteiller communicates to the *Mouvement Medical* (No. 24, 1868) the following case: On July 13, 1867, he was called at three o'clock in the morning, to render professional service to a young man who had ripped open his belly with a knife. He had eaten nothing since twelve o'clock the previous morning, but had indulged in copious libations during the day. At eleven o'clock at night he repaired in a state of insanity, to the house of a lady, in whose company he found her brother. He then, in a fit of jealousy, cut himself with the knife. (The instrument is not described.) His relatives, shortly after informed of the accident, took him home in a carriage, and sent for Dr. Bouteiller. The surgeon found a transverse wound, a centimetre and a half in length, situated 2½ cent. to the left of the median line of the trunk, and 3 cent. below a horizontal line passing across the navel. In the morning, Dr. Picard was called in consultation, and they diagnosed a hernia of the inferior extremity of the spleen, about 4 cent. in length, strangulated in the centre of the wound. A ligature was passed around the protuded portion of spleen, and cold emollient applications were made to the abdomen. Vomiting had taken place, but contained no traces of blood. Retention of urine supervened, requiring the use of the catheter. July 14 and 15.—Some pains in the belly, especially in the vicinity of the wound; complete repose. Fomentations all day. Soup. July 17.—The ligature came away. Simple dressing. The patient was well by the 23rd. During these ten days, there was scarcely any fever, except perhaps during the first two days. The patient was examined May 1st, 1868. There was a linear cicatrix of a little over 1 cent. in length. The health is perfect, and the patient attends to his affairs as well as before the accident. He has not a very great appetite, and is conscious of rumblings in the region of the stomach after indulging in a hearty meal. What is remarkable in this wound, remarks Dr. B., is the hernia of the spleen, through a narrow wound, situated near to the middle line. Besides, this young man had not eaten since morning, and the accident occurred at 11 o'clock at night. It is not probable, therefore, that his stomach was distended. But it must be remembered that the wound was made by the right hand, and consequently directed obliquely toward the left side; and in addition the motion of the carriage tended to increase any disposition to protrusion,

ALCOHOL IN LARGE DOSES IN POISONING BY MUSHROOMS.

M. **Poulet**, in a communication to the Académie des Sciences, affirms that alcohol in large doses is a veritable antidote to the poisonous mushrooms of the genus *amanite*; and he believes it equally valuable in the poisoning by other species of mushroom. The author adds that ebullition in water impregnated with salt or vinegar, is insufficient to render the poisonous varieties inoffensive, and that the *agaric bulbeux* in particular always retains a great portion of its toxic principal.—*Gaz. Hebd.*, 1864, No 41.

THE INTRODUCTION OF THE CLAMP IN OVARIOTOMY.

Mr. T. **Spencer Wells**, writes as follows to the editor of the *Boston Med. and Surg. Journ.*, in reply to a letter from Dr. Parks, inquiring who was entitled to the honour of having inventing the clamp used in his operations in ovariotomy:—"The credit of the introduction is due to Mr. Hutchinson, Surgeon to the London Hospital. He first used one in 1858. It was simply the common calliper of carpenters, which he used and left applied, handles and all. Then the handles were made moveable, so that they could be taken off as soon as the clamp was fixed. Then I made the blades parallel, and did without handles. But I afterwards returned towards the original form of clamp, altering the joint and the form of the opposing surface of the clamp until I arrived at that which I now use. You may see it figured in Druitt's Vade Mecum, ninth edition, 1865, page 541. I have now (Jan. 25, 1869), completed three hundred cases. Of the

1st	100	cases,	64	recovered	and	34	died.
2nd	100	„	72	„	„	28	„
3nd	100	„	77	„	„	23	„
Total	300	“	213	“	“	85	“

A general mortality of 28 per cent., but it is very encouraging to note that the mortality has been steadily diminishing with increasing experience." Since October last he has completed the operation of ovariotomy in 36 cases. Of the 36 women, 31 recovered and five died; and it is a remarkable fact that in *every case* in which the pedicle was long enough for him to use the clamp the patient recovered.

OSSEOUS REGENERATION OF STERNUM.

Dr. **Enrico Bottini** communicates to the *Annali Universali di Medicina* the particulars of the case of a soldier, æt. 30, wounded in the superior region of the sternum during the Italian campaign of 1866. The ball lodged, producing caries, necessitating an operation for its removal, which exposed the pleural sac, the osseous walls of the sternum having been gradually absorbed, and a prompt recovery ensued, and new osseous tissue was formed analogous, in resistance to the touch, to the rest of the sternum.

ADULTERATION OF MILK.

Edwin M. Snow, M.D., of Providence, Rhode Island, states, in a "Communication on the Adulteration of Milk," that the average specific gravity of milk from any dairy should not be lower than 10·30. In Providence the milk-dealers impoverish thin milk by removing the cream and adding water. Most of the samples examined by him gave an excessively alkaline reaction, while pure, fresh milk should be slightly alkaline. This can be easily accounted for from the fact that bicarbonate of soda is frequently added to raise the specific gravity. He believes it were better, both for the producer and the consumer, if a small quantity of the bicarbonate, say a teaspoonful to the gallon were added immediately after cooling. This would neutralize a small quantity of acid first formed and prevent the rapid souring of the whole mass.

CASE OF APHASIA. BY G. W. H. KEMPER, M.D. MUNCIE, IND.

On January 3rd, I was called to see, in consultation with Drs. Jump and Kerr, Mr. Thomas Stanford, residing near New Burlington, in this county. Mr. S., at the time of his death, was seventy-four years old. His life had been characterized by extreme vigour of body and mind. For several years he was a member of our State legislature, and at various times has held minor county offices. During the latter part of last December, he noticed that he had some trouble about taking the proper length of steps in walking. Some times he would, contrary to his will, step too far, and at other times not far enough. He noticed this irregularity and spoke of it to his family, but nothing serious was anticipated, until Tuesday, December 29th, when he sat down to breakfast and commenced saying grace, but kept repeating the same word for some little time. Finally, his wife spoke to him and asked what was the matter. He replied, nothing, and exclaimed "how singular," and then proceeded to eat. During all this day, his memory of words would fail him, and he found much difficulty in making known his wants. Desiring a younger son to start to school, he said, "Go to—to—to—," and seemed puzzled that he could not finish the sentence. Some one said, "To school, father?" and he replied yes. On Wednesday morning, having some business to transact with a neighbour, he attempted to write a note, but kept writing the same word. He tried for half an hour, but was compelled to give it up, although an excellent penman. At this period, Dr Jump was called to see him, and found his condition as follows:—No pain in any locality, pulse 100, full and regular, tongue furred, pupils unchanged, temperature normal, appetite good as usual, no paralysis or even numbness. Dr. Jump prescribed a mercurial cathartic, to be followed with oil or a saline cathartic in four hours, if the bowels were not moved, a warm pediluvium with mustard, restricted diet, and potass. iod. in five grain doses three times a day. Dr. Kerr, a son-in-law, who lived some distance, came on Friday and remained with him until his death. We saw him, in consultation, at twelve A.M., on Sunday, January 3rd. His condition was similar to what it had been since Wednesday. He seemed cheerful and lively, and desirous of conversing, but forgot so many words that it was impossible, frequently, to understand him. He would smile at his inability to call words, and seemed much perplexed. Pointing to Dr. Kerr, I asked him if he knew him. He replied yes. What is his name? He smiled confusedly, and said "It's—oh—it's—oh—." I named over several fictitious names, but he would reply no. I then said Kerr. He replied, "That is right." I was shown some of his writing, in which he attempted his own name as follows: "Thos. Thom. Stans." He remained in about the same condition until January 4th, at ten A.M., when he was seized with a convulsive fit, lasting about a minute and a half, and immediately expired. No *post-mortem* was made.—*Western Journ. of Med.*

POISONING BY CHLORODYNE.

It has been remarked that the cases in which Belladonna has been used as a remedy in Opium poisoning have generally been very far from conclusive. The same may perhaps be said of the following, but it is not without interest, especially since observations of the kind are not very numerous. It occured in my practice about two years ago, and the notes were taken at the time. An old woman, upwards of eighty years of age, swallowed a quantity of Chlorodyne, equal to about three fluid drachms. The exact time was not known, but when seen at 4 p.m. she was sick and vomited. She continued quite conscious till about 5 p.m., and after that time she lay in a state of stupor, snoring very loudly at first

I saw her a little after 8 p.m. She was then quite unconscious; limbs quite flaccid; jaw dropped; skin warm and perspiring; pulse full and slow; breathing very slow and interrupted—three or four gasps and then a complete stoppage, sometimes for as long as two minutes. The symptoms were markedly those of Morphia poisoning, the pupils being contracted to the size of a small pin-head. I injected one-twelfth of a grain of Atropine in solution subcutaneously. About a pint of water was introduced into the stomach, and drawn off again by means of the stomach pump. The fluid had a faint smell of Chloroform, and was slightly brown in colour. About half a pint of strong tea was then poured down through the tube and left in. Hot bottles were applied to the feet, between the thighs, and to the region of the heart. Friction to the legs was used, and an enema with Turpentine given, which was retained. In about twenty minutes after the Atropine was given the pupils began to dilate, and she showed the first sign of consciousness by closing her teeth on the tube of the stomach pump. Her appearance on the whole improved, the colour of the face becoming more natural, and the intervals between the respirations shorter. The pulse varied a good deal, but was generally about 80 or 85. I remained till about eleven o'clock, and on leaving gave orders to continue the rubbing aud the warm applications. I saw her again at 1 a.m. Her breathing was then almost natural. She moved her lower jaw, and when a few drops of wine were poured into her mouth she made an effort to swallow, and even moved her shoulders a little. The pulse, however, was weaker, and the extremities beginning to be cold. She gradually sank, and died about 1.40 p.m. The Chlorodyne was made according to the ordinary published formula, containing four grains of Muriate of Morphia to the ounce, so that she probably took about a grain and a half. How much may have been vomited I have no means of knowing. The improvement in her condition must be ascribed to the Atropine, as it was quite noticeable before the tea was introduced into the stomach. The pupils dilated rapidly, and after two hours contracted a little again. I am inclined to think that recovery would have taken place if the patient had been younger, or if she had been seen and treated sooner. The improvement, even in such desperate circumstances would encourage me to make use of the same remedy in another similar case. In order to test the effects of Morphia and Atropine, when given simultaneously, I tried an experiment on my own person by injecting subcutaneously a solution containing one quarter of a grain of the Morphia and one twenty-fourth of a grain of Atropine. At the time of making the experiment I was in good health, pulse 60. In fifteen minutes the pulse rose to 76, in twenty minutes to 88, and in half an hour to 104. The pupils at that time were very slightly dilated, and there was considerable dryness of the throat and mouth. I felt slightly giddy, but with a slight effort could walk steadily. On the whole, the sensations were not unpleasant. About an hour after the injection I went to sleep, but could not have slept very profoundly, as I awoke about four hours after, when a slight knock was made on the door. When I rose I had a good deal of difficulty in walking steadily especially when turning a corner. Mouth and throat were dry, speech somewhat indistinct; and vision slightly impaired. At that time, however, I felt neither sickness nor headache. These came on two or three hours after, though not very severely, and I did not during the day feel so much languor as on a previous occasion, when I used Morphia alone. Perhaps the dose of Atropine was large in proportion to that of the Morphia but certainly the symptoms occasioned by it were most marked. The narcotic influence of the Morphia certainly was not heightened. As regards the amount of Atropine that may with safety be injected hypodermically, there is a considerable difference of opinion. Dr. Garrod says the dose should be from one two-hundred and fiftieth of a grain upwards. Trousseau, in his Clinical Lectures, speaks of one-tenth, or even one-fifth, of a grain not being excessive; and again, Dr. Nussbaum, of Munich, in the section on Anæsthetics in Pitha and Billroth's "Handbuch der Chirurgie," now in course of publication, gives it as his experience that one-eighth of a grain may produce dangerous symptoms; but that he has often given one-sixteenth without any bad effects. I once injected one-sixteenth of grain in a case of neuralgia but the symptoms, though not alarming, were so disagreeable, that I would scarcely use the same amount again until I saw the effects produced by a smaller dose.

INVERSION OF THE UTERUS.

James Blake, M.D., Professor of Obstetrics and Diseases of Women and Children, Toland Medical College, reports a case of inversion of the uterus, in the *Pacific Medical Journal.* He says the child was born two hours before the arrival of the physician, the woman going on comfortably but the placenta had not been delivered. In attempting to deliver the placenta, the uterus was inverted. The placenta which was adhering to the inverted uterus was removed. It was followed by a great deal of flooding. Unsuccessful attempts were made to reduce the uterus. After five or six hours another physician was called in, and an attempt was again made at reduction, but owing to the prostration of the patient, had to be discontinued, as manipulation of the uterus increased the hæmorrhage. After twenty-four hours, the patient having partially rallied, a persistent attempt to replace the uterus was made under the influence of chloroform but failed. On the 29th of September (two days after the child was delivered), Dr. Blake was sent for, but could not be found, and another physician returned with the messenger. Kept the woman three hours under the influence of chloroform but failed to reduce the inverted uterus. Dr. Blake having been sent for, advised the friends, as the patient was comfortable, and no hæmorrhage, to wait until the third week after labour, when the process of involution is the most rapid. He accordingly visited the patient on the 22nd of Oct., gave her chloroform, and in thirty minutes, by Dr. Emmet's method, reduced the uterus. Dr Blake thinks that from the facility with which he reduced the uterus, that his course of treatment, viz.: in waiting until three weeks after labor, was the proper course to pursue in such cases.

Dr. A. K. Reynolds, St. Louis, reports a case of inversion of the uterus, in the *Humboldt Med. Archives.* which he reduced after four and a half years' duration:—"On the 28th of May, in the presence of Dr. DeFoe (in charge) and Dr. G. G. Lyon, of Alton, by request of the former, I attempted the reduction of the inversion, but after a patient and careful manipulation for one hour, a greater length of time than generally deemed advisable, it was found necessary to abandon the attempt for that day, the rigidity of the cervix being too great to admit of reduction without injury to the parts. Upon consultation, it was then decided to introduce an elastic air-bag, for the purpose of supporting the tumour, distending the vagina, and relaxing the rigid contraction of the cervix. The bag was inflated by means of a large syringe, and was allowed to remain twenty-four hours at a time, the parts being washed out, and the secretions removed each morning, before its re-introduction, by injections of warm water. Morphiæ acetas was ordered to allay irritability, and although the effort at reduction was, as stated continued for an hour, it was followed by neither pain, fever, or inflammatory action. On May 31st, Drs. DeFoe and Lyons again present, it was found that the air-bag had been of great benefit, both in supporting the tumour and distending and relaxing the parts, the extreme rigidity of the os and cervix having in a great measure disappeared. By request, as before, I made a second attempt at reduction, which, in thirty minutes was completely successful. After reducing the fundus almost within the cervix by manipulation the operation was completed by means of an instrument made as follows. A piece of wood was turned like a small top, with the larger end concave. To the smaller end of this was screwed an iron wire, three-sixteenths of an inch in diameter, having a suitable wooden handle, and the larger end was covered with a thickness of cotton batting, and this again with oiled silk. When finished the instrument was of a suitable size to pass easily through the os and cervix, and receiving the fundus in its cup shaped cavity or depression, could follow it up, where the hand could no longer be used to advantage. August 15.—The patient is now in perfect health; says she never felt better in her life. There has been no return of the displacement, and the cervix is normal in appearance. The cure is perfect, and seemingly, there is now nothing to prevent her bearing children again. The only medication to which she was subjected was the use of morphia, as already stated, and subsequently, being anæmic from previous loss of blood, tinct. ferri. chlor. gr. 30, ter die, was prescribed by Dr. DeFoe, and continued for some time.

THE PONS VAROLLI THE NERVOUS CENTRE OF GENERAL CONVULSIONS.

H. Nothnagel (*Virchow's Archives*) arrives at the following conclusions with regard to the *nervous centre of general convulsions*, which are derived from actual experiments. The centre of general convulsions is situated in the substance of the pons. Its lower boundary is corresponding to a section at the height of the inferior border of the pons. The faculty to perform the function of a centre of spasms is to be denied to the substance of the medulla oblongata. Finally, he endeavours to prove that the spasms are produced by way of reflex. In some instances the section of the medulla oblongata had been made below the pons, the animals remaining absolutely quiet. Again; the convulsions occurred if the section had left a portion of the pons connected with the medulla oblongata, showing the centre of action to be situated outside of the medulla. At last the anatomical condition of the region of spasms is confirmatory to the view of reflex action. The region nearly corresponds to the situation of the grey nuclei and root-fibres of the sensitive cranial nerves. While the nuclei and roots of the motor cranial nerves are near the raphe, those of the sensitive nerves are more lateral. The root fibres of the portio major trigemini, in particular, descend, according to Schroeder van der Kolk, through the whole length of the medulla. This anatomical condition, it must be conceded, is no direct proof of a reflex action, but it renders it admissable and plausible. From all this it seems that the convulsions following the injury of a defined region on the floor of the fourth ventricle are to be explained as spasms induced by reflex action.

ECTROPIUM INTESTINORUM.

A MOTHER, twenty-one years of age, was delivered of a male child, in which the following state of things existed:—From an opening two inches in length at the umbilical region, ¼ inch to the right of the umbilicus, and parallel to the linea alba, bulged out the greater portion of the intestines. Their coats were hypertrophied, and the abdominal walls were to such an extent contracted as to allow only the admission of the small finger on both sides of the orifice. The rigidity of the abdominal wall did not allow of any stretching. It was an eight-months child, passed its natural secretions, fæces and urine. In the morning it vomited bile, and in the afternoon nursed at its mother's breast; its pulse was regular, as was also its respiration. The portions out were made up by the duodenum, jejunum, and ileum of the small intestines, and the colon and a portion of the rectum of the large intestines. The child died the day after its birth having lived exactly twenty-one and a half hours.—Geo. Fredigke, in *Chicago Medical Examiner*.

DILATATION OF THE OS-UTERI AND PERINEUM DURING LABOUR.

DR. G. KILNER (*Chicago Med. Journ.*), in a communication upon this subject, recommends, when other medicaments have failed the use of lobelin. He praises its efficacy, and recommends that a suppository be made of lobelin, gr. v., to cacao butter, ʒ j., and introduced into the rectum immediately upon the subsidence of a pain, and also anointing the os with the same. He states that fifteen or twenty minutes' retention of the suppository is generally sufficient to produce complete restoration of the os and perineum.

GOITRE CRETINISM.

M. GARRIGON, consulting physician to the Mineral Springs, of Aix, asserts these endemics are due to the existence of magnesia, and more especially to the silicate of that earth, in the soil, which modifies all organisms, both vegetable and animal. His doctrine is based upon extensive observations made in the districts of the Pyrenees where these maladies are endemic, and are coincident with such geological constitution.

HYPODERMIC INJECTIONS OF MORPHIA IN LABOUR.

Dr. E. KORMAN, Leipzig (*Am. Journ. Obstetrics*), considers hypodermic injections of the sulphate of morphia superior to any anæsthetic during labour. He injects very slowly one-eighth to three-fifths of a grain in the thigh. The indication for the injection are: Primiparæ, narrow pelvis, spasmodic contractions, and painful complications generally.

MOVEABLE BODIES IN THE BLOOD.

DR. K. BETTELHEIM found in the blood of a patient suffering from hæmorrhagic variola, a rather large quantity of small bodies, punctiform, partly rodlike, bustling about like vibrions partly between the money-rolls, like arranged blood-corpuscles. The same bodies were found in two cases of typhus exanthematicus, one of echinococcus hepatis, one of intermittens, one of chlorosis, hysteria, syphilis, scarlatina, pneumonia, etc. They were also found, but in not so great a number, in the blood of a considerable number of healthy persons, who had been examined with the greatest caution; altogether, Dr. Bettelheim finds blood, in which these bodies are missing, more often than when they are present. He therefore thinks that their pathological importance should not be over valued.

He observed the following three kinds:

1. Such bodies, which magnified 630 times, steadily appear as punctiform dark bodies, moving about rather briskly in to and fro waving excursions.

2. Very small bodies, just perceptible when magnified 1,400 to 1,500 times, moving about vigorously.

3. Larger, distinct redlike structures, of the size of half the diameter of a blood-corpuscle or a little smaller; they have a tumescence at the end, which appears as if it were separated from the rest of the little rods by being unstringed. Their motion is plain but slower. It seems, that besides their motion in toto, a wave-like motion goes on in themselves.

FISH AS AN ARTICLE OF FOOD.

PROFESSOR Agassiz, in his address before the Committee of the Legislature of Massachusetts, on the propagation and preservation of fishes, says, as reported in the *Boston Journal*: The fish enters largely into the requisitions of the human system. It is a kind of food which refreshes the system, especially after intellectual fatigue. There is no other article of food that supplies the waste of the head so thoroughly as fish diet: and the evidence of it is in the fact, that all the inhabitants of the sea-shores the world over are the brighter population of the country. Fish contains phosphorus to a large extent, a chemical element which the brain requires for growth and health. He would not say that an exclusive use of fish would make a blockhead a wise man, but that the brain should not be wanting in one of its essential elements."

TONKA BEAN IN PERTUSSIS.

IT having been suggested that the tonka bean would be useful in pertussis, as it contained a large percentage of coumarin, the active principle of clover-tops, trifolium melilotis, recommended for that disease, to test its qualities it was given to a child three years old, with encouraging results. Subsequently it was given in four other cases, two of which were of a grave type. The oldest—a girl five years old—was a great sufferer, the paroxysms being frequent and exceeding severe, and disturbing her sleep frequently during the night. She began with five drops of the fluid extract every three hours, increased to eight after the third dose. Relief was soon felt, and the paroxysms gradually subsiding she soon slept all night, and her cough now seems more like that of an ordinary cold. In the tonka bean I think we have a means of saving many lives, besides giving relief to all who suffer from the disease.—JOHN COOPER, M.D., *in the Med. and Surg. Reporter*.

ON THE ANTAGONISM OF YELLOW FEVER AND CATARRH.

WM. H. FORD, M.D. (*N. O. Journal of Medicine*), in an article upon this subject, gives the following as the conclusions at which he has arrived: 1st. That epidemics of yellow fever and of catarrh *never* co-exist. 2nd. That break-bone fever may occur in a summer, neither generally catarrhal or generally miasmatic, and that the disease affects principally the origin and decline of the yellow fever, when it occurs in a miasmatic season, and the *acme* of the season when it qualifies a catarrhal epidemic. 3rd. That when catarrh occurs during the prevalence of yellow fever, the catarrh is "sporadic," and that catarrh is mostly absent during yellow fever seasons. 4th. That when yellow fever occurs during the prevalence of catarrh, the yellow fever is "sporadic," and that yellow fever is mostly absent during catarrhal seasons. 5th. That catarrh prevails almost exclusively during the origin and decline of yellow fever. 6th. That the yellow fever, when it appears during a catarrhal season, affects the most miasmatic part of the season, viz., the end of September and the beginning of October. 7th. That from the recorded history of the only visitation of Asiatic cholera to our city (New Orleans), as an epidemic, this disease undeniably shows a miasmatic origin, by exhibiting relations to catarrh precisely similar to those which obtain between yellow fever and catarrh. We therefore conclude generally that from a consideration of forty-two years, yellow fever is directly antagonistic to catarrhal diseases.

HYPODERMIC MEDICATION.

S. F. STARLEY, M.D., in closing a paper upon this subject, gives the following important testimony to the efficiency of this treatment: "I have used quinine hypodermically some hundreds of times, and with the exception of two or three cases of abscess which gave little trouble, and the case of sloughing of a small portion of integument, have seen no ill result follow its use. But on the other hand, its effects, when administered in this way, have been so prompt and so permanent, that several persons to whom I have given it, now refuse to take the remedy by the mouth at all, and when quinine is prescribed, they insist upon having it injected under the skin."

IDIOPATHIC PRIAPISM.

J. R. Smith, M.D., has reported it the *N. O. Journal of Medicine*, a case of persistent priapism, occurring in a patient about twenty-five years old. He had had gonorrhœa seven years before, but was not left with stricture, and had not had connection for nearly two weeks previous to the priapism. In spite of most active treatment applied most assiduously, the priapism continued for about ten days. At the end of this time he was sent to a different part of the country, and the "disease gradually, and almost imperceptibly gave way."

DEATHS BY POISON.

In the five years 1863-67, the number of persons who met with violent deaths by poison in England and Wales was 2,097. In 1,620 cases the description of poison is recorded thus:—By arsenic, 83; mercury, 58; opium, 114; morphia, 32; laudanum and syrup of poppies, 426; strychnia, 41; prussic acid and cyanide of potassium, 151; essential oil of almonds, 31; oxalic acid, 66; sulphuric acid, 58; nitric acid, 16; muriatic acid, 5; carbolic acid, 5; salts of lead, 242; improper medicine, 17; overdose of medicine, 52; Godfrey's cordial, 56; improper food, 33; aconite, 6; belladonna, 6; alcohol, 35; ammonia, 8; hartshorn, 3; chlorodyne, 4; vermin killer, 20; turpentine, 3; phosphorus, 15; sulphate of copper, 3; colchicum, 3; disinfecting fluid, 3; nitrate of potash, 3; chloride of zinc, 8; spirits of salt, 8; cantharides, 2; fungi, 6; mussels, 8.

◆

THE DUBLIN HOSPITALS.

We understand that the subject of the grants and modes of election in the Dublin Hospital, will be under discussion in the Statistical Society of Ireland on Tuesday evening next, and that members of the committees and of the medical staff of these institutions, will be freely admissible, and will be allowed to take part in the proceedings.

◆

NOTICES TO CORRESPONDENTS.

If all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

Enquirer.—Reply next week.

Dr. Martin's letter shall appear shortly.

Dr. McDowell.—As soon as possible.

Mr. Donovan.—The letter is in hand.

Mr. Macalister's paper was duly received.

A Country Practitioner.—On Herpes in our next number.

Dr. Thos. Dervis's Case of Extra-Uterine Fœtation shall be published.

Dr. Waring-Curran is thanked. The paper on Hydrocephalus will appear shortly.

The file of the *Indian Medical Gazette* is received with thanks, and our journal will be sent from this date.

The remaining portions of Dr. Palfrey's fifth Lecture "On Fibrous Tumours of the Uterus," is unavoidably held over till our next.

Dr. Ewing Whittle, Liverpool.—Your letter headed "A Daniel come to Judgment," in reply to Dr. Drysdale's published in our last, is unavoidably held over for want of space.

Dr. J. Woods Beck.—Your note upon "Silver an unoxidizable Metal," has been handed to our Analysts. We are always open to correction, and shall be happy in our next to give space *to*, or notice *of*, your letter, dissenting from the statement made on this subject in our Analytical Reports.

Our Analytical Department. Cocoas.—Through press of other matter, we are compelled to hold over our final Report and Summary until our next. We regret being obliged at the last moment, to postpone this Summary, which has now been in type several days, but, for the above reason, we are reluctantly forced to do so, notwithstanding the interest which has been generally created by the analyses of the past weeks.

Mr. H. Eschwege.—Your letter, with reply thereto, shall appear with the final Report on Cocoa in our next. *Ad Interim*, Van Houten's Cocoa, for which you are the sole agent in Great Britain, will be again submitted to analytical and microscopical tests. Should we find our first Reports—which were very carefully done—incorrect in any particular, we shall be but too happy to give you our verdict for the superiority you claim. The fact of Dr. Hassall having given you such a *flaming testimonial*, will not weigh one *iota* for, or against you in these Reports.

NAPOLEON I.—A SANITARIAN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It is to be hoped that the *dicta* of the *Lancet* on strictly professional subjects are more reliable than its utterances on matters of general interest. To judge by the remarkable instance of the latter, which appeared in its columns on Saturday last, under the heading of "Napoleon I., A Sanitarian," it would seem that certain superannuated opinions of the age of Fox and Holland, when Napoleon's good fortune and success were yet unbroken, still linger among the traditions of the *Lancet* proprietary staff.

Without supposing the existence of such traditions, it would be impossible to account for the profound admiration with which the editor of that journal has been seized, on discovering, in the "correspondence of the Emperor Napoleon," into which it would appear he has been dipping, a document ordering that the system of sewage conservancy which, at that time, was universal in France, as it previously was, and has since remained, should be put in force in some new town that he was projecting in Elba. From this slender and most common-place *datum*, we are told not only to infer that the first Napoleon was a "sanatarian," but, with all we now know of his pusilanimity and dastardly meanness in adversity, to believe that the "force of character and genius of this great soldier and monarch sustained him under difficulties and misfortunes unparallelled."

There is something truly humiliating in this wonderful display of ignorance, which the average schoolboy of any modern European country (pupils of the *Lycées impériaux* excepted), would at once detect; for it proves how deep is the impression that can be made on the minds of men by unprincipled egotism, unscrupulous rapacity, and unblushing mendacity.

The editor of the *Lancet*, in my humble opinion, might, with great advantage to himself and his readers, substitute for the recreation of his leisure hours, a recent work which has made some noise in the world, and is entitled *Histoire de Napoléon I., par* P. Laufrey, for the sophisticated correspondence issued by the present Imperial Governor of France.

Yours obediently,
A Non-Medical Outsider.

London, June 9th, 1869.

APPOINTMENTS.

Baker, H. F., L.S.A., Midwifery Assistant at St. Bartholomew's Hospital.

Batt, C. D., M.B., House-Surgeon to the General Infirmary, Sheffield, vice C. J. H. Smith, M.R.C.S.E., resigned.

Bell, J. A., M.R.C.S., late House-Surgeon, Resident Accoucheur to St. Thomas's Hospital.

Caton, R., M.B., Assistant-Physician to the Liverpool Children's Infirmary.

Douglass, G., M.D., Medical Officer to the Gateshead Dispensary, vice Wm., Jollie, M.D., deceased.

Hardyman, C.E., M.R.C.S., L.S.A., House-Surgeon to St. Thomas's Hospital.

Jukes, A. M.R.C.S.E., House-Physician at St. Bartholomew's Hospital, vice P. J. Hensley, M.B.

Lowther, R, M.B., C.M., M.R.C.S.E., Resident House-Surgeon to the Infirmary, Lancaster, vice Wm. Armistead, M.B., resigned.

Macnamara, R., L.K.Q.C.P.I., President of the Royal College of Surgeons, Ireland, in succession to G. H. Porter, M.D.

Pollard, F., L.R.C.P., M.R.C.S., House-Surgeon to St. Thomas's Hospital.

Roberts, F. T., M.B., B.Sc., Demonstrator of Anatomy at University College, London.

Ross, J. A., L.R.C.S.I., Resident Medical Officer to the North Staffordshire Infirmary, Stoke-upon-Trent.

Smallman, R. S., M.B., House-Surgeon and Secretary to the Hartlepool Hospital, vice J. Rawlings, M.R.C.S.E., resigned.

Squarey, C. E., M.B., M.R.C.P.L., Resident Medical Officer to University College Hospital, Assistant-Physician to the Hospital for Women, Soho square.

BY ROYAL LETTERS PATENT.

Dr. HASSALL'S FLOUR OF MEAT.

Universally Approved by the Medical Faculty,

FOR THE IMMEDIATE PREPARATION OF BEEF TEA,

CONTAINS THE WHOLE OF THE CONSTITUENTS OF THE MEAT,

Including Fibrin, Albumen, and Gelatine; is more nourishing than many times its weight of Raw Meat; requires no mastication, and is easy of digestion.

INVALUABLE for use in the Army, Navy, and Merchant Service, to Travellers, Tourists, and Sportsmen, and it is of vital importance to all Hospitals and Asylums in which the Sick are congregated, and to Invalids generally, especially those suffering from Dyspepsia and Debility arising from Defective Assimilation and Nutrition. The BEEF TEA made with the FLOUR OF BEEF IS FULLY EIGHT TIMES STRONGER AND MORE NOURISHING THAN BEEF TEA MADE IN THE ORDINARY MANNER, and far more nutritious than the Beef Tea (so called) prepared with LIEBIG'S EXTRACT, which does NOT contain Fibrin, Albumen, Gelatine, or Fat—the very principles which give the body its size, weight, and strength.

"Impossible to over-estimate the importance of the Concentrated Flour of Meat."—*The Lancet.*

"The Committee has every reason to believe that this is a preparation of considerable value."—*Society of Arts.*

FLOUR OF BEEF FOR BEEF TEA, packages, 2s. and 4s.

John Bell and Co., Oxford street; Savory, Moore, and Co., Bond street: Fortnum, Mason, and Co, Piccadilly; and all Druggists and Italian Warehousemen; and Wholesale of

CROSSE & BLACKWELL, SOHO SQUARE, LONDON.

*** *This will be found a most delicious relish as a Sandwich, or spread on Toast or Biscuit. Mix a portion with the Butter before spreading.*

Lecture.

ON FIBROUS TUMOURS OF THE UTERUS.

By James Palfrey, M.D., M.R.C.P.,

Assistant Obstetric Physician to, and Lecturer on Clinical Obstetricy at the London Hospital; formerly Obstetric Physician to the Farringdon Lying-in Charity, and to the Metropolitan Free Hospital, and to the Surrey Dispensary, &c., &c.

LECTURE V.—Part II.

In this way you will be able to conduct your patient for a very considerable period until the increase in the size of the growth, or the peculiarity of its position become the cause of constant pain of a wearing character, which pain, as I have shown you, may be constant or paroxysmal in its appearance. At this time you must begin to employ sedatives for the relief of this suffering, or your patient will get worn out and exhausted. At first a quarter of a grain of acetate of morphia combined with a couple of grains of ext. of henbane or conium, administered at bedtime, will be sufficient to ensure a sound and refreshing sleep, and very often enable your patient to get tolerably well through the day; or, if she complain of pain then you may, at intervals after food, give a dose (♏vj to ♏xx.) of the tincture of Indian hemp, always adopting the precaution of combining this preparation of the drug with some form of mucilage, to prevent the precipitation of the resin of the hemp. Sooner or later, however, you will be compelled to increase the quantity as also the frequency with which each dose of the sedative is administered. I cannot tell you definitely as to the quantity you are to give. You must be guided solely by the condition of each case and by the amount of pain present in each individual example of the disease. Some of these cases of fibroid will get on for years with but a moderate quantity of morphia; on the other hand, you have seen among our patients women who have gradually arrived at six, eight, or ten grains of morphia every night, and large doses of Battley's Solution in the daytime. Again, it is true that hæmorrhage is not a very frequent symptom of interstitial growths, yet now and again you will meet with exceptions to this rule, and the same remark applies to leucorrhœa; but as I shall be obliged to speak at some length of the treatment of these troublesome conditions further on, I will leave all I have to say until that occasion. The only other point, then, that occurs to me to touch upon concerning these interstitial fibroids is the painful vaginal and rectal tenesmus which often causes so much distress to the patients. You will find the former invariably relieved by a warm bath, which, in the absence of any hæmorrhage, is always a valuable aid to treatment; this bath to be succeeded by rest for several hours in the recumbent position, and follow this by the use of the elastic belt I have already spoken of. For the rectal congestion and tenesmus I know of no more certain remedy than a free *saline purge*; and in my own practice, as you know, I employ the mist. mag. cum mag. sulph. I will simply on this point add a word of caution: be exceedingly careful to avoid the use of drastic aperients in these cases. I have more than once seen a smart attack of bleeding follow rapidly on a dose of colocynth and aloes; hence never prescribe these drugs in cases of fibrous growths.

We come now to speak to you of the treatment of submucous, or the third variety of fibrous tumours. You will remember that in describing them I told you that this form of tumour is developed immediately beneath the mucous membrane lining the cavity of the uterus; that they project into that cavity; and that, as their name implies, their covering is simply an extension of the lining membrane of the organ. Now I remind you of these points because you will presently see that they are surgically of great practical importance. I am able to assure you that the form of disease, the treatment of which we are now entering upon, is capable of the most decided, and, with ordinary care, the most effectually radical treatment. At starting, however, I find myself called upon to speak of some operative procedures that have in this and other countries been adopted only to enlist from you their complete condemnation. In the year 1840, M. Velpeau, and, a little time afterwards, M. Ammusat, suggested that these hard sub-mucous tumours of the womb should be removed by an operation, which is termed enucleation; their example has been followed by several operators in this country. It consists first of an opening being made into and through the os uteri internum, sometimes by incision, at other times (as in the case related by Sir James Simpson) by the potassa fusa, or, as in Dr. C. West's case, by the removal of one or other uterine lip; the hand is then partially or wholly introduced into the cavity of the womb, and the tumour is "shelled out" from its uterine envelope. You will, even from this brief description, readily understand, I feel sure, that the operation is one attended with great danger, that it is long in its performance and the statistics of all the operations for the removal of these growths by enucleation go to prove that the chances of the patient who undergoes the operation escaping destruction, either immediately by shock, or a few days later by uterine inflammation, or later still by pyæmia, are very small indeed. Twice I have operated in this way in cases that appeared peculiarly favourable for its performance. The first case occurred to me in 1859, in the person of a widow, æt. thirty-six, who had for years been suffering from the hæmorrhage and other symptoms caused by the presence of a sub-mucous fibroid, the size of an orange, in the posterior wall of the uterus. This woman was exceedingly anxious, before a second time entering into the married state, to be rid of her tumour. From the moment I began to introduce three fingers into the os uteri, previously dilated by sponge tents, until I brought out two-thirds of the growth, one hour and sixteen minutes elapsed. The patient died, to all appearances, of pure shock, two hours and ten minutes after being removed to bed. I operated on the second case in February 1861. The patient was forty years of age; the growth was much larger than in the former case. I had previously opened up the cervix to a large extent, and I succeeded in getting away, partly by shelling, partly by the scissors, more than a third of this large tumour. I was compelled somewhat abruptly to finish the operation, in consequence of the gentleman who was administering chloroform assuring me that the patient was getting exhausted. Being placed in bed, she rallied under the free use of brandy and other diffusible stimulants; but she died four days subsequently, with all the symptoms of active uterine and pelvic inflammation. The impression made upon my mind by the disastrous termination of the two cases quoted above, together with the results of the recorded cases of others, have induced me to refrain from ever again attempting this (to my mind) dangerous and hazardous proceeding. Should you wish to become more intimately acquainted with the steps of the operation, I can refer you to the works of Sir J. Simpson, "Obstetric Memoirs," vol. i. p. 118; Dr. West, "Diseases of Women," 3rd edition, p. 305; and to a very able article on the "Surgical Treatment of Fibrous Tumours of the Uterus," by my colleague, Mr. Jonathan Hutchinson, in the fourth vol. of Holmes' System of Surgery.. I can only for myself say that I know of no circumstance that should induce me again to attempt to perform this, almost certainly, fatal operation, and the more so, seeing that I shall immediately have to describe to you a surgical proceeding very far less dangerous in its performance, and in my own experience infinitely more satisfactory to the physician and beneficial to the patient in its results.

Dismissing, then, this operation of enucleation, we come to the symptoms of sub-mucous growths, and, following the plan adopted in our second lecture, we must speak first of the treatment of hæmorrhage, for you will find that symptom, as a rule, to be the earliest, and very often for a long time, constitutes the only, indication afforded us of the presence of a tumour of this kind. At first it appears in the form of a prolonged and profuse menstrual period, the discharge being mixed with clots of greater or less size, the bleeding in each case being ushered in with severe cramp-like pains. After the lapse of time, which varies, as I have before pointed out to you, according to the age of the patient, the size, position, and character of the growth, hæmorrhage between the periods appears. Now, whatever may be the cause of this dangerous symptom later on in the progress of these cases, the impression on my mind is very clear and distinct that in the earlier stages of the development of these sub-mucous growths the hæmorrhage is caused in this way. As soon as the growth has attained the size of a pigeon's egg, the parenchyma of the uterus, as well as the lining membrane, undergo extensive changes, the blood vessels enlarge, first within the uterine wall, subsequently those of the mucous membrane, which soon becomes tumefied and hyperæmic, in fact a true congestion of the uterus results. Now, add to this the displacement, more or less complete, which we so constantly find resulting from the presence of these tumours, and you have, to my mind, a satisfactory explanation of this early hæmorrhage; and if you will examine carefully for yourselves, you will soon, I believe, be satisfied that the cause is the one I have just stated. Now, to go a step further, if you believe this, how very simple the management of this form of hæmorrhage becomes! Recall to your minds the treatment you see us so constantly suggest in the numerous cases of bleeding arising from uterine congestion that come before us. It consists first in absolute rest. Have I not shown you that in the most active form of this bleeding it is frequently sufficient to put the patient to bed, to cover her lightly, and in a few hours the hæmorrhage of itself ceases? and this plan is still more likely to be of advantage, if you, some twenty or thirty hours before the menstrual period is due, freely purge your patient with a saline aperient. As the growth increases in size, however, the hæmorrhage becomes more troublesome, and then you will be called upon, in addition to the rest, to employ some other means; and I repeat that I know of no method more successful than the application of leeches to the vaginal portion of the uterus; four or six, is the number I usually suggest, and if you find the bleeding continue profuse and the patient getting exhausted, I advise you at once to employ the leeches; do not allow the bleeding to wear itself out, it will cease, I assure you, within a very short time, usually an hour or two, of the dilated and engorged bloodvessels of the uterus being relieved of some of their contents, and this leeching you may safely repeat from time to time as long as any tenderness continues to be present. Here let me ask you to make yourselves acquainted with the very simple steps that form the procedure of leeching the neck of the uterus. I shall not detain you now by describing it. It is constantly done in the obstetric ward, and with equal frequency among the out-patients. Those of you who will practise in the country will especially find it desirable to be acquainted with these apparently small details, for you will be unable there to command the services of our nurses, who so admirably assist us in this respect in London. Returning, then, to this subject of hæmorrhage, I must tell you that very often you will not be called to these cases of sub-mucous fibroids until the patients are already seriously reduced and exhausted by repeated and persistent bleedings. You must in these cases abstain from local depletion. Still you have at your command a means of staying the bleeding, which you will find in the highest degree serviceable. 'I mean the cervical plug; the method of its employment is simply this, expose the os uteri with a Sim's speculum, steady the cervix with the small hook so familiar to you all, upon the point of a long steel rod carry up to the os a narrow strip of lint, six or seven inches long, the end of which has been previously dipped in a saturated solution of the perchloride of iron, very gently and slowly, little by little insert this into the cervical canal. To me it has proved invaluable in those cases in which the local abstraction of blood has been inadmissible. You may leave the plug in its position in the cervix for thirty hours, or even longer, and upon its removal, which is effected by withdrawing the vulval end of the lint (absolute rest, I hardly need remind you being at the same time maintained), I have been accustomed to order the tepid vaginal douche, previously adding ʒj. or ʒiss. of tannin to the water to be used. I have never seen any ill effects result from the use of the plug, such as distension of the cavity and fallopian tubes, or peritonitis, accidents mentioned by Dr. Barnes and M. Bernutz as likely to occur.

Now, I must say a few words upon the class of remedies which are known by the name of uterine hæmostatics; and it is in the form of hæmorrhage I have just mentioned that these drugs will be found of most service, although they are in my opinion of but little use in checking or staying a bleeding from the uterus so long as the patient maintains the horizontal position. In fact, I must tell you that all your efforts to be of service to these patients will be fruitless, unless you can command their entire confidence, and your success in every case will be exactly proportionate to the extent to which your patient is willing to suit her own wishes, tastes, opinions, and desires, to your conscientious efforts to cure her of her malady, or alleviate her sufferings. Many drugs have obtained the reputation of being uterine styptics. Some deservedly so when administered under favourable conditions, others are in my judgment valueless, Among the former class I may name ergot of rye, gallic acid, matico, digitalis, turpentine, cinnamon, Indian hemp, opium, perchloride of mercury, &c. In the second class those that I have invariably found to be powerless to restrain bleeding from the womb, I place acetate of lead, oxide of silver, arsenic (and all forms of iron when administered during a bleeding), sulphuric acid, alum. The most useful of these, and the combination I believe most effective, is, ergot, gallic acid, and opium. The formula I order in most cases is as follows:

℞ Acidi gallici gr. x.
Aquæ ferventis ʒiv. ♏ fiat.
Solutio et postea adde—
Extracti ergotæ: Liq. ℥j.
Liquoris opii, sedativ. Battleyii ♏ x.
Syr. aurantii ʒss.
Aquæ cinnamomi ad ʒj. ♏ fiat haustus.

This I continue to administer at intervals of two, three, or four hours, until the bleeding has entirely ceased; at times the ergot disagrees, causes vomiting or severe headache, in those cases I have tried, not unfrequently with marked benefit, the iced water enemata, and at other times, when the growth has been of considerable size, a bladder of ice kept for several hours in the supra pubic region. Again I carried out in several of these cases the plan advocated by Drs. Savage and Routh, of injecting the tincture of iodine into the uterine cavity, having previously dilated the cervix by sponge tents; the effect in each case was decided but transitory, the bleeding returning in a couple of months or less. Lastly, here I must tell you, that in well-selected cases the perchloride of mercury has appeared to have a remarkable power of checking the bleeding caused by these sub-mucous growths. These varied and various plans of treating the hæmorrhage will each in turn assist you, but, without doubt, sooner or later the hæmorrhage will return. Metorrhagia will be added to the prolonged menstruation, or they will at last run one into the other, and then the question will force itself upon you, Is there nothing left but to abandon these cases to their fate? I am glad to tell you the answer is at once clear, and I believe conclusive. You can not only arrest the bleeding, but you can, by interfering with and destroying the nutrition and integrity of these sub-mucous fibroids, produce a slow destruction of their substance. The history of the operation I am about to describe, and very earnestly to urge upon your adoption, is singular. Quite independently of each other, Mr. Baker Brown, Dr. McClintock, and M. Nélaton of Paris, after repeated trials, came to the conclusion that a bold and free incision of the os uteri is very generally followed by a marked decrease in the hæmorrhage that attends these growths. Mr. Brown added another step to his procedure, he removed by cutting or gouging a part of the growth, this latter portion of the operation being performed at an interval of twenty-one or thirty days after the incision of the cervix. Still more recently this gentleman has abandoned any interference with the growth in those cases where the tumour is of small or moderate size; in this, however, I cannot agree with him, for, in every instance in which I left these cases with a simple incision of the neck, the bleeding has returned at an interval varying from sixteen months to two and a quarter years. I do not, however, attempt now, as I did in my earlier operations, to remove any portion of the growth, but I make a jagged and ragged opening in it, in a way presently to be described; subsequently keeping this opening patent by strips of lint applied from day to day. If you desire simply to arrest the violence of the hæmorrhage doubtless for a considerable time, the bilateral incision of the os uteri will effect this; but I believe after a time, *as the growth increases*, the cause of the hæmorrhage again returns, and your patient is much in the same condition as before. Various explanations having been given to account for the success of these operations, more especially upon the rationale of the incision of the cervix, which, as I have stated, is sufficient of itself to arrest the bleeding, in these cases, at any rate for some time, I should occupy a very considerable portion of your time if I were to attempt to place before you even an outline of the views of the various obstetricians who have endeavoured to explain the *modus operandi* of this proceeding. I shall in this case, as before, content myself by referring you to the several works of the authors I have referred to. You will remember, when speaking of hæmorrhage as a symptom, I said that my own opinion as to its precise cause was still unsettled, and that I could not definitely lay down to you the cause of the great bleeding that takes place in these cases. The same remark will apply to the point we are now considering, although I have a strong impression that in the cases of the larger growths the bleeding arises from two sources: 1st, from the engorged blood-vessels of the investing membrane of the tumour; and, 2ndly, from the dilated blood-vessels of the turgid and congested cervix, which, being subject to constant and considerable pressure by the tumour from above, the circulation through that portion of the organ is retarded and impeded, intense venous engorgement results, and from time to time an attempt is made to relieve this state by the pouring out of large quantities of blood from the mucous surface of the cervical canal. Whatever the real explanation may be, the fact remains, that the free incision of the os and cervix is followed in nearly every instance by a cessation of the profuse bleeding. I need hardly tell you that, like every new proceeding introduced for the cure of a malady hitherto supposed to be beyond the reach of medicine or surgery, this operation has met in the obstetric world with many warm supporters, and with not a few equally sincere opponents. There have been operators who have resorted to the incision and gouging in nearly every case of fibrous disease, without regard to its position, size, or relations to the uterus; they have, in fact, regarded the operation as the *omnium curum* of fibroids. These attempts have not unnaturally been followed by severe disappointment to the operators, and injury—and in some instances even death—to the patients; while, on the other hand, there are still living teachers of the obstetric art in this town who perseveringly maintain that an occasional saline rhubarb powder, the daily administration of some few doses of hyoscyamus and sumbul, combined with the use of an elaborate abdominal support, embrace the whole resources at our command for the cure of these formidable cases. Gentlemen, as is always the case, the path of safety lies in the middle of these extremes. A careful selection of the cases, mostly of the sub-mucous form of the disease, and those cases again which are uncomplicated with any organic disease of other organs, the careful preparation of the patient previous to the performance of the operation, the removal as far as possible of congestion of the uterus by rest, leeching and the other means I have mentioned, a regulation of the digestive organs and the intestinal canal by suitable medicines, constitute the precautions which, if observed, render this operation in my opinion and in my experience one of the most valuable, most effective, and most successful in the whole range of obstetric surgery. In my sixth and last lecture I propose to conclude this subject by describing the operation to you as I now usually perform it, and then say something on the subject of polypi.

GLEANINGS IN TOXICOLOGY.

No. VI.

By Charles Meymott Tidy, M.B., M.S.,
Joint Lecturer on Chemistry at the London Hospital.

There is no test for strychnia so remarkably delicate, so absolutely certain, and so little liable to mistake, as its physiological effects on frogs. A solution where the colour tests may fail to give us satisfactory, or indeed any results, will produce, when injected under the skin of a frog, characteristic symptoms which are perfectly unmistakable. Dr. Marshall Hall, to whom we are indebted in the first instance for the test, recommends that the solution be merely applied to the skin; but there can be no question, I think, that the injection of the solution under the skin of the back, or into the abdominal cavity, will yield more marked effects in a far shorter time. Dr. Harley even asserts that on injecting 1-18,000th of a grain of the alkaloid into the lungs of a very small frog, tetanic convulsions occurred in nine and a half minutes, and death in two hours.

The following may be regarded as the ordinary course of symptoms. The frog, first of all after administration, remains for a short time perfectly quiet, and then succeeds a slight difficulty of breathing; which, after a varying time, dependent partly on the dose, considerably increases, the animal gasping as if for life; a slight tremor then becomes visible over the entire body, and this is particularly marked in the hinder legs. The animal will sometimes remain at perfect rest for a short interval, at other times it will give several energetic and convulsive leaps; and now follows the characteristic tetanic convulsions. Occasionally on their first appearance the animal will make a strange shriek, as if of pain, at the same time turning over and over from side to side. But this shriek, described by some as always occurring, may certainly be wanting; the spasms are not continuous, but may instantly be produced by touching the frog, or, indeed, by merely knocking the table with the finger. The pupils dilate during the spasms, but contract during the intervals. Very frequently the action assumes the form of "emprosthotonos," which, according to Dr. Harley, is more common in the frog than "opisthotonos," the reverse of this being the case in man.

The following are the details of some experiments on frogs, which I copy word for word from my note-book.

1. Injected 1-2,000th of a grain of strychnia under the skin of the back of a small frog. In thirty-six minutes it was slightly convulsed. In forty-eight minutes convulsions were very strong; could not walk. Recovered.

2. The same effects noted when injecting the same quantity into peritoneum; convulsions occurred in about twenty-five minutes. Recovered.

3. Injected 1-4,000th of a grain under the skin of the back; convulsed on touch in about forty-eight minutes.

4. The same effect and in about the same time, when injected into the peritoneum.

5. Put a frog and a toad into 500 grains of water, containing 1-2000th of a grain of strychnia. No effect.

6. Put into the mouth of the frog (a large one) a drop of a solution containing 1-2,000th of a grain. No effect.

7. After twenty-four minutes, put 1-500th of a grain into his mouth; went off into a strong convulsion twenty-two and a half minutes afterwards, turned over on his back, and was convulsed for some hours. Recovered.

8. Gave toad by mouth 1-1,000th of a grain in two drops of water. It had a fit produced by touch in one hour and twenty-six minutes. Recovered.

9. Gave a toad 1-400th of a grain by mouth; convulsions came on after 34 minutes. Recovered.

10. Gave a very large frog 1-300th of a grain by mouth; was convulsed on touching him about four minutes after it had taken it; danced on top of its toes, then laid on its side panting. Went off again and again upon repeating the touch. Recovered.

11. Gave 1-2,000th of a grain to a very small frog by mouth. Had convulsions on touch thirty-six minutes afterwards.

12. Gave a very large toad 1-2000th of a grain by peritoneal opening; convulsions occurred in thirty minutes.

13. After three hours injected another 1-2000th of a grain into peritoneum. Died in forty-eight hours.

14. Gave 1-2,000th of a grain to a toad by mouth. Spasm in three hours.

15. Gave 1-1,000th to toad by injection under skin of back; convulsions in two and a half minutes.

16. Gave 1-2,000th to frog by injection under skin of back; convulsions in forty-five minutes.

17. Carefully injected 1-5,000th of a grain under skin of back of a very small frog. Convulsions in thirty-eight minutes.

18. Repeated experiment in another very small frog with 1-8,000th of a grain; a decided convulsive tremor occurred in about forty minutes.

And now a few words upon the action of strychnia on the body. Although a poison which seemingly acts so energetically on nerves, its direct application to a nerve will produce no effect on that nerve, nor can a nerve convey the poison into the system; for no poison can destroy life until it has, in some way or another, entered the blood, nor have the lymphatics even any power to carry the poison. And, moreover, it is not the nerves which are the actual seat of the disease. It is the spinal cord, and that only; the nerves merely acting as the telegraph wires to convey the effects of the disease from the spinal cord to the extreme limits of the body. All these facts are capable of direct proof by actual experiment. And thus, to sum it all up in Dr. Harley's words, to whom we are indebted for many valuable experiments on this subject, "the vessels convey the poison to the spinal cord, the spinal column becomes supercharged like a Leyden jar, and the nerves are the wires which distribute the shocks."

The exact mode in which strychnia destroys life may be regarded as yet as an unproved problem. It may be, as some have supposed, by *suffocation*, from the action of the respiratory muscles being interfered with from spasmodic action; or from a closure of the glottis from the same cause, inducing *asphyxia;* or, lastly, purely from *exhaustion*. To discuss these points, however, would lead me beyond the limit I have proposed to myself in these gleanings.

One other question suggests itself. How long after death is it possible to detect strychnia? A most important question, as those who follow the evidence given in toxicological cases will bear witness, and a question, moreover, which has received very different answers. My own firm conviction is that strychnia is not decomposed by contact with putrefying or decomposing animal or vegetable matter, or with substances in a state of active fermentation. Indeed, of so permanent a nature is it, that the blood, the secretion from the skin, and the urine, will all more or less yield traces of the poison in patients who are taking it in merely medicinal doses.

And now for an experiment which I believe will place beyond a doubt this point to which I am referring. At the time of the memorable trial of Palmer for poisoning Cook (1856), Dr. Letheby put half a grain of strychnia in a bottle with a dog's stomach and what appears to be pieces of human liver. This bottle had been entirely forgotten until one day when clearing out some old bottles I happened to come across it. With some difficulty we made out the label. On that Dr. Letheby referred to his notes, and found a memorandum as follows:—

"May 4th, 1856, put 0·5 gr. of strychnia in wide-mouth bottle with dog's stomach, &c."

Clearly, then, this bottle had stood by above twelve years. I at once made an analysis, to see whether I could detect the strychnia; and although I only operated on a quarter of the contents of the bottle, and which contained consequently not much more than 1-10th of a grain of strychnia, I had no difficulty, following the process proposed by Mr. Rodgers, in making out its presence by the characteristic colour tests. And this after it had stood for this long period in contact with decomposing animal tissues. Indeed, it seems (providentially, I think) that it is an organic compound that resists most means of decomposition; and, to use Mr. Rodgers's own words, "Putrefaction, so far from interfering with the separation of the strychnine, greatly facilitates it." Mr. Rodgers has found it twelve months after interment. If, then, there is the slightest reliance to be placed in experiment, this truth is certain, that strychnine in contact with dead or living matters is left untouched—undecomposed; and not merely so, but after having been mixed for months with strong mineral acids, it is left with all its properties as they originally existed. And if we fail in detecting it, if a considerable time has elapsed between death and its administration, it is not that it has been decomposed, but simply that it has been completely eliminated from the system. It is this absolute certainty that renders chemical science such a mighty aid to legal investigations, and so invaluable as a means not merely of convicting the guilty but of clearing the innocent; for if strychnia causes death, only provided that sufficient time has not elapsed for it to be entirely eliminated, it is in the body, and the toxicologist should find it, no matter whether the examination is made immediately after death, or whether years have elapsed between the fatal result and the analysis.

And here these gleanings must close, to be resumed, if possible, at some future time.

◆

CASES IN COUNTRY PRACTICE.

EXCISION OF CHRONICALLY ENLARGED TONSILS.

By Thomas Hayes, M.D. Edin., M.R.C.S. Eng.

When I was a student excision of the tonsils was so seriously dwelt on by my instructors, and so anxiously talked about by my fellow-students, that, I believe, the effect was to produce a profound impression on every medical tyro that it would be better for the reputation of the majority of practitioners to allow the tonsils to remain for ever enlarged, rather than have recourse to the knife or guillotine for their extirpation. I believe their removal by excision is still looked upon by many country surgeons as a complete *bête noir*, and, having the fear of the internal carotid or ascending pharyngeal arteries before their eyes, few venture beyond caustic, tincture of iodine, and constitutional treatment, which, from the small effects produced and the annoyance of repeated applications, will be often pronounced "almost as bad as the disease." I must also admit that my personal experience as a pupil was far from convincing me that removal of the tonsils by excision was quite a simple procedure. I have seen both knife and guillotine wielded by highly skilled hands, and such struggling, such choking, such apparent agony of a patient held by five or six students; and the result—a few bits of torn tonsil—neither satisfactory nor encouraging.

In publishing a few cases out of many, some of which I trust are not devoid of interest, I have no desire to claim originality in the mode of procedure. My principal object is to inspire more confidence in my country brethren, and to show them that excision of the tonsils is safe and easy in practice, and that it will give more speedy and permanent relief to the patient than all the remedies in the Pharmacopœia.

Enlarged or hypertrophied tonsils, besides being in themselves a morbid growth, give rise to local and sympathetic irritation, a constant tickling of, and inclination to clear, the throat, irritation of the larynx, pain in the head and ears, and also to grave constitutional effects by interfering with the arterialisation of the blood, by obstructing respiration by their increased size, or by vitiating the current of air on its passage to the lungs (and persons so affected generally breathe through the mouth). Enlarged tonsils also interfere with deglutition and the digestive functions, add to these some physical defects in hearing and articulation, and we have a short summary of the different causes which demand, in addition to the anxiety and urgent entreaties of the patient, a speedy, safe, effectual, and, as far as may be attempted, complete removal of the tonsils.

I have, during the past ten years, removed the tonsils from several patients in the most simple manner, a long artery forceps supplying the place of the volsellum. I find that with the artery forceps you can take hold quite gently of the tonsil and bring it sufficiently forward to slip it off without producing any sense of choking or causing the patient to struggle. I scarcely ever require an assistant to hold the patient. I depress the tongue with the finger only while seizing the tonsil; I do not as a rule have the patient held, and have found no reason to do so; if very young I direct a person to keep a steady watch on the hands and head to prevent a sudden starting. I find that "self-reliance," and the fact that the patients feel themselves "free and unfettered," is a grand point gained in preventing spasm and struggling.

I first seize the tonsil very lightly with the forceps, not including much of its substance; then cut with a probe-pointed bistoury, generally from below upwards, but sometimes—as when the tonsils are more enlarged near the tongue than towards the soft palate—from above downwards, directing the edge of the knife when completing the operation towards the mesial line, to avoid injuring the tongue or soft palate, removing rather an oval portion than a section or plane, so that in the contraction which follows the isthmus would regain its natural shape. I endeavour to educate my patients to be calm, steady, and to avoid catching at me; and I find they are more frightened at the prospect of the operation than with the thing itself. I never cover a part of the blade with lint; I do not think it necessary, but I keep the point of the knife quite close to the back of the tonsil, so that, if necessary, it might be withdrawn as rapidly as possible. When removing the right tonsil I place the patient on a low chair or on the floor; then, standing to the right and a little behind, I throw back the patient's head, and pass my left hand over the left side of the face, seize the tonsil and remove it, using the knife with the right hand.

This last position of the patient and operator is similar to that usually adopted in extracting the posterior molars of the upper jaw. I find it much more easy and less awkward to proceed in this manner than to cross the hands, especially where any clumsiness or want of steadiness might mar the operation.

Mrs. L., æt. twenty, married, of very healthy appearance, consulted me for "lumps in the throat" of some duration, from which she felt a great deal of uneasiness, soreness, pain on swallowing, and a constant "hawking" or wish to clear the throat of some thick mucus. She expressed a special wish that the "lumps" should, if possible, be removed by operation, rather than have recourse to medical treatment. I found the tonsils enlarged, conical, hard, and prominent, somewhat larger than a horse-chestnut at the base. I had neither volsellum nor guillotine at hand. I thought I could take hold of them with a long artery forceps, which I found on trial admirably realised my expectations. I took hold of the tonsil with the forceps, pulled gently towards the middle line, and slipped it off with the bistoury on a level with the arches of the palate; there was no struggling, no hæmorrhage—a slight oozing only. I deferred removing the second until I ascertained the result. I did not lose sight of the risks, dangers, and gloomy consequences that might ensue. All went on well, there was no inflammation, the part healed rapidly, and the patient was highly pleased. My experience being thus far satisfactory, I removed the second a week after without the least hesitation. No after consequences ensued; no after treatment was found necessary. It is now eight years since the operation was performed. She enjoyed uninterrupted good health during the time until three months ago, when she consulted me for an attack of articular rheumatism. She has had three children since I removed the tonsils. I mention this in compliance with a wish expressed by that gifted professor, Dr. Mapother (I believe at a meeting of the Surgical Society), for information regarding the antaphrodisiac effect which was said to result from removal or disintegration of the tonsils. I have no doubt the distinguished physiologist does not require to be convinced by statistics that this old opinion is anything more than a silly exploded medical superstition.

Miss O'R., æt. thirty, unmarried, has been suffering from "sore throat" for a few years; is very subject to catch colds; has some pain and difficulty or rather uneasiness in swallowing. Tonsils in a state of chronic enlargement; removed them with artery forceps and bistoury at one sitting. Parts healed rapidly without further treatment; eight years since operation; no uneasiness of throat nor further enlargement since operation; is now married, and has one child.

Annie McC., æt. seven, a beautifully fair, plump, and healthy looking little girl, was brought to me to the dispensary by her mother, who stated that she had a "horrid choking in the throat at night when she went to sleep," and that the mother was quite afraid her little girl would not live till morning; that this troublesome state had continued for some time, but was growing much worse lately; and that she was also subject to starting in her sleep. On looking into the throat I found both tonsils enormously enlarged in every direction, filling up the whole isthmus, and feeling pretty hard. There was no difficulty of breathing, no cough; nothing, in fact, appeared to be wrong until the throat was examined. The tumours had all the appearance of slow growth, there was no vascularity, no softness, no acute sensibility in them. I intended treating them locally and constitutionally with nit. argent. tinct. iodine externally, and the administration of cod-liver oil, hg. c. cret., and syrup of iodide of iron; and was giving directions accordingly, when the mother beggingly entreated me to do something for her immediately, "for God's sake," or that she would not stay in the house with her child at night. I was very reluctant to interfere with the knife in so young a child, but the entreaties of the mother compelled me to do something. I found no difficulty in seizing the tonsils, for, notwithstanding the youth of the patient, she was very manageable, and only required to have the head gently held. I could not venture to remove the whole tonsils (I mean on level with the arches of the palate); I contented myself with removing a portion of both; made a gap in the blocked up isthmus. There was no bleeding, no subsequent swelling or inflammation. I removed another portion of each a week later, repeating the process at regular intervals until both were cut on a level with the arches of the palate. This little patient has continued healthy since a period of three years.

Bridget McM., æt. eight, a thin, rather pale, freckled, sandy-haired little girl, was brought to my dispensary by her mother, who stated that for some time she was growing very delicate, and that she complained of her throat being sore; but what alarmed her most was the disagreeable and troublesome way in which she breathed when she went to sleep, and the "choking" noise she made. I found the tonsils enlarged in every direction, being clearly perceptible externally at the angles of the jaws; the isthmus fauceum was nearly filled up; the surface of the tonsils was broad and somewhat lobulated. I removed a portion of each then, and repeated the operation a few times until they were reduced to a small size, and ceased to be troublesome. No after consequences of any kind ensued. I then gave remedies to improve the general health. It is now more than three years since I operated, and she has enjoyed complete immunity from the tonsils, and her general health has continued good.

Master B., æt. fifteen, is delicately formed, though enjoying pretty good health from his infancy; has enlarged tonsils for a long time; has some thickness and indistinctness of speech, and slight dulness of hearing. I attended him in scarlatina about six months before removing the tonsils; being previously hypertrophied, they increased so much in size during the scarlatinal illness that the throat was entirely blocked up. Although there was very little ulceration, they pressed closely against each other, so softly, however, that I could pass a mop, charged with solution of nitrate of silver; he became comatose during the attack, which I attributed to the effect the tonsils exercised on the respiration in his then state. In a family of ten attacked with scarlatina at the same time, he was the only one who showed comatose symptoms, and he had no other complications than those stated to account for it. He made a good recovery, with tonsils, however, much more enlarged than previously. After a little time I removed them, to his great relief.

Miss O'S., æt. twenty, a strong, healthy young girl, came some distance to have "lumps in the throat" cut out, as she suffered much annoyance from them. I found both tonsils chronically enlarged, and removed them at one sitting, without having her held or causing her to resist or struggle in the slightest degree. The parts healed rapidly; no inflammation; no subsequent inconvenience from the tonsils.

I may here remark that I have seen very little loss of blood after removing the tonsils, and that little ceases soon after operation. The blood vessels, if not obliterated or compressed by the growing mass, at least do not seem to increase and multiply in the same ratio as the hypertrophied glands.

I could add many more cases, successfully and satisfactorily treated in the same simple manner, without any untoward circumstance occurring, but I believe those given will be found quite sufficient to demonstrate the success of the means employed. I believe there is no remedy for tonsils so sharp, short, and decisive as the knife, and none more likely to produce results so pleasing to the patient and the surgeon.

◆

THE INFLUENCE OF CONSTITUTION IN SYPHILITIC DISEASE.

By B. Kelly, M.D., L.K.Q.C.P.I.

Since the syphilitic virus, when applied to an abraded surface, is followed by effects very different in appearance and gravity, some being well marked in their specific character, while some are entirely negative, in other words, giving rise to no local or general phenomena whatever, we may reasonably infer that the fault lies not so much in the quality and nature of the poison as in the physical condition or diathesis of the individual subjected to its action. We have no hesitation or fear, as far as tainting the system in general is concerned, to inoculate with matter taken from a Hunterian or other chancre a person who has already been the victim, or is yet suffering under the influence of constitutional syphilis. All we need apprehend in either case is the gravity of the local lesion, which is sometimes very serious, giving rise, as it occasionally does, to phagedenic, serpigenous, and gangrenous ulcers. This remarkable disparity in effects naturally suggests the question: "Is the syphilitic virus in all primary sores one and the same?" I believe it is; but I would add this qualification to my article of faith, that it is always identical only in the very early stage, before it has become adulterated, and its specific quality vitiated and changed by being mixed with the products of the local inflammation, which accompanies its development.

The matter of a Hunterian chancre, previous to the induration, is perfectly similar to that of the soft phagedenic and serpigenous varieties, if examined, or experimented with in its recent state; but if tried at an advanced period, we find it as inert upon the living tissue as the pus of an ordinary furuncle. The reason of this is obvious. In the indurated infecting sore the virus is soon absorbed into the system; and the matter which appears, when the induration is fully established, results from the inflammatory process which necessarily attends every breach of continuity, however minute. We see, on the contrary, that the matter of the other forms mentioned maintains indefinitely its specific character, the virus, instead of undergoing general absorption, remaining stationary, and acting as a corrosive irritant upon the tissue in contact with it, and imparting to the *detritus* which ensues most, if not all, its poisonous properties.

A grave error, I think, is sometimes made by calling chronic syphilitic ulcers of a tertiary or quaternary kind with hardened edges, "indurated sores," as such a nomenclature is liable to lead to a confusion of ideas in many minds, the term "induration" naturally conveying the notion of a primary Hunterian chancre. The mere fact of their sometimes affecting the genitals and neighbouring parts should not make us lose sight of their true constitutional character. Another important reason why we should have a correct appreciation of the nature of such sores is, that the treatment best adapted to one form is either inadequate or injurious to the other, and *vice versâ*. The autoinoculation with the matter of these chronic ulcers, I may add, will always give negative results, and hence another source of fallacy into which we are so liable to fall.

The matter of a suppurating bubo, it is well known, is not always the same as regards its specificity and virulence; the bubo depending upon the direct absorption of syphilitic matter from a primary sore; a soft chancre, for instance, always yields a liquid highly infectious; whereas the adenitis produced by a Hunterian or infecting sore, whenever it suppurates (which very rarely happens), gives rise to a purulent discharge entirely analogous to that of an ordinary abscess, being absolutely devoid of all specific and virulent properties. The difference in both cases consists in this, that suppuration in the first example is inevitable and essential, the virus being conducted from the primary sore along the interior of the lymphatic vessels leading to the inguinal glands, which thus become effectually inoculated; whereas it is purely accidental in the other, the glands being sympathetically affected, take on suppuration through the agency of external causes. This is proved from the fact that constitutional or specific adenitis located in other regions of the body little exposed to irritation—those of the neck, for instance—rarely or never suppurates.

These peculiar phenomena, readily accounted for and perfectly simple in other respects, lose much of their historic, if not pathological, interest when we turn to another stage of the disease, and note as well the variety of the constitutional symptoms, as the order in which they make their appearance.

We see, for instance, that rupia, acne, roseola, ecthyma, lepra, psoriasis, &c., follow an infecting chancre, when left to the resources of nature; but very rarely (as far, at least, as I have observed) do any two of them present themselves simultaneously in the same subject, unless we except the *maculæ* which are not unfrequently their concomitants. Here again the question recurs: "Does this difference in the external characters of the secondary symptoms depend upon some subtle and mysterious quality of the infecting virus?" I think there cannot be the slightest reasonable doubt that each variety is the evidence of a modification which the poison has undergone during its period of incubation in the system, which modification is itself the result of the peculiarity of individual constitutions. We find almost invariably, that rupia, impetigo, and ecthyma appear in persons of strumous and cachectic habits; that lichen, acne, and roseola single out the healthy and robust; while the squamous syphilides usually show their partiality for individuals of an intermediate class. We might, indeed, *à priori*, and independently of observation, infer that such should be the case. This view, moreover, would seem more probable than that which attributes the diversity of the eruptions to an organic and fundamental difference in the virus from which they severally spring. Do we not see, for instance, that the vaccine lymph, when taken from the same vesicle and applied to children of different constitutions, is followed by different effects? In the healthy it usually runs its course without any serious local or constitutional symptoms; while in scrofulous and delicate subjects, we not unfrequently find that abscesses, diphtheritic inflammation, eczema, and glandular enlargements supervene upon its successful insertion. Mothers invariably attribute all these untoward accidents to the operation of bad matter; and designing practitioners and knavish charlatans are not slow in turning the foolish prejudice to their own account. It would be quite as reasonable, and certainly more honest, to refer rupia and ecthyma, for instance, to *bad syphilitic virus*, rather than to any modifying action impressed upon it while pervading the systems of persons presenting these eruptions.

Inoculation of variola, as well as vaccination, fails in producing its ordinary effects in certain constitutions, and owing to certain diatheses, malignant pustule and anthrax, as observed by Ricord, frequently remain local affections for similar reasons, and are capable of being cured by topical applications. Are we, then, to be surprised that syphilis frequently and necessarily fails to reduce the general system under the sway of its ruthless dominion, and is forced, so to speak, to exhaust its malignity upon circumscribed and barren ground?

Other facts of a kindred order to those mentioned would seem to justify the opinion that the syphilitic virus is identical in its original essence, and that whatever anomalies it presents to the contrary depend upon extrinsic circumstances.

It is noticed that in the monkey, for instance, notwithstanding the facility with which he is inoculated with matter taken from a chancre during the stage of specific progress, the animal seems to enjoy an entire immunity from the common consequences of constitutional infection, secondary or tertiary symptoms never having been known to follow the operation. This, doubtless, is due to the greater plasticity of the blood in the inferior animals, and the habit they have of licking their sores. In the monkey we also see that the artificial chancre invariably tends to cicatrize by a healthy and rapid granulation, thereby ensuring the complete expulsion of every molecule of virus, until the animal is at length entirely freed from the unnatural infection. In man the susceptibility of falling a prey to its virulent power is infinitely greater, modified, however, as I have intimated, by individual constitution and idiosyncrasy.

A good example of this peculiar modification is shown by the manner in which a simple chancre is aggravated by the depraved habits of the debauchee and confirmed drunkard. Ricord has called such sores *œnophagedenic*. The same author asserts that the pultaceous, the serpigenous, the diphtheritic, and other varieties of the corroding chancre are the result of hygienic circumstances, and that they depend, in a great measure, for their virulence and obstinacy upon the diathesis of the patient, be it scrofulous, scorbutic, or cancerous. It is thus we find that the matter taken from the same pustule, the same impure fountain, will produce, when transferred by inoculation, a soft non-infecting sore in one subject, a Hunterian chancre in another, whereas it may fail to develope anything more serious than an insignificant chancroid vesicle in a third.

The different effects shown in these instances cannot certainly be attributed to a difference in the nature of the infecting virus, since it is furnished from the same source.

A strange peculiarity of the manifestation of syphilis in the human subject is occasionally shown by the manner in which the secondary and tertiary symptoms appear as regards priority.

When the disease is abandoned to nature, secondaries generally follow the Hunterian sore, and are regularly succeeded by tertiary accidents. This may be appropriately styled the stereotyped order of their apparition. In exceptional cases, however, this order is reversed, and then we have tertiaries preceding the secondaries, which may appear, or may not, according as the disease is actively treated, or simply left to the resources of nature. This anomaly is fraught with considerable perplexity to the practitioner, and inconvenience, if not danger, to the patient, as the former may not always be able to decide whether tertiaries or secondaries, as the case may be, had already existed, and the latter may be subjected to inadequate, or improper medication, and be dismissed as cured before the system is fully cleared of the infection and guaranteed against a subsequent relapse. According to Ricord, this anomaly is due to treatment. "More powerful," he says, "against secondary than tertiary accidents," mercury sometimes prevents the manifestation of the first, and permits that of the others. Thus, after a chancre has been treated by mercury, the first constitutional manifestation may consist of an exostosis, and appear to certain persons, who cannot count except upon their fingers, a secondary accident of a tertiary form, as though it were merely this character which decided its nature. In the same manner, and under the same influences of treatment, secondary accidents may be manifested after the tertiary. . . . . But all this, he continues, "so far from being disorder, is only an effect of art, and demonstrates its power."

It is to be regretted that the caustic sarcasm of the great specialist is not well supported by logical reasoning. For, if all this, as he would have us believe, were merely an effect of art, it would be infinitely more common, as an accident, than it really is. How much more probable is the hypothesis that the reversal of the usual order of symptoms depends rather upon idiosyncrasy, or individual constitution; and that the mercurial treatment, far from being a determining cause, is merely a coincidence? This view, indeed, of the subject seems to be corroborated by observations upon the effects of mercury in the treatment of primary syphilis. The great majority of cases do well under the judicious employment of the medicine, both secondaries and tertiaries being prevented by its use. In a few exceptional instances, however, it fails to check the development of either, and even aggravates their character.

I remember distinctly a case in point, the history of which may serve as a good illustration, and throw some light upon this obscure subject.

A patient presented herself some three years ago with well-marked tertiary symptoms, in the form of periostitis, ulcerated throat, and ozæna. She was immediately put under a course of iodide of potassium, and improved very perceptibly up to a certain period, when suddenly, and without my being able to account for the extraordinary change, all her symptoms became greatly aggravated. I changed the treatment by substituting mercury. This only made matters entirely worse. I then prescribed the chlorate of potash, which more than satisfied my most sanguine expectations. The ulceration of the throat and nares rapidly healed; and the patient was dismissed under the impression that no further trouble was to be apprehended. She returned, however, after an interval of a few weeks, presenting as well-marked an eruption of syphilitic roseola as ever came under my notice. This form of the disease was treated by the bichloride of mercury, and with the most satisfactory results, the patient being quickly relieved of her nocturnal pains, and (what she deemed of far greater importance) her obnoxious eruption. This case is, I consider, of much interest in a double point of view; as showing the curious anomaly of secondaries succeeding tertiary symptoms after their complete disappearance, and (as it was with good reason supposed) their radical cure; and again as demonstrating the utter failure of mercury and iodide of potassium in the treatment of the tertiary symptoms, as they manifested themselves in this particular instance; whereas the subsequent secondaries yielded readily (as indeed they generally do) to small doses of the former agent. The patient, I may add, was of a very robust constitution, and strongly disposed to obesity.

The order in which the secondary symptoms usually appear is remarkable, both as showing the influence of constitution in determining the form of the eruptions, and also as fixing the different, yet definite, epochs of their manifestation. On first thought, one would be inclined to suppose that the more cachectic the constitution, the more precocious would be the development of the secondary symptoms. This, however, unfortunately for the hypothesis, is not the case. There is, perhaps, but one single exception to the truth of this fact, and that is furnished by the mucous papule, which is generally formed towards the end of the second week following an impure intercourse, either upon the site of the primitive sore, or in other regions of the body. The subjects in whom this accident occurs are usually persons of a lax, lymphatic constitution; and hence we find that roseola and erythema, acne and lichen, are among the foremost fruits of the syphilitic infection; while ecthyma and rupia tardily follow in the distance—the latter scarcely ever making its appearance before the second or third year. The squamous and vesicular eruptions, as lepra, psoriasis, ptyriasis, eczema, &c., occupy an intermediate place in a chronological point of view. It would seem, indeed, to possess all the force and truth of an axiom, that the more depraved and altered the constitution, the more protracted will be the first manifestation of the secondary symptoms. Hence their total absence in individuals who have already been the victims of the syphilitic taint, and their great rarity in the immediate descendants of syphilized parents.

Another fact of some importance to mention is, that ulceration of the skin does not take place in the exanthematous and squamous syphilides, while it is not at all uncommon in the pustular and tubercular varieties.

Although secondaries of the exanthematous and papular types are the earliest to make their appearance, they are by no means the most frequent, the squamous and vesicular forms far exceeding them in this respect. This may be due to the circumstance, that inasmuch as mediocre constitutions out-number the very good and the very bad, the eruptions which generally affect those of the former class must necessarily predominate; and hence the comparatively great rarity of erythema and roseola, ecthyma and rupia, as seen in persons ranked in the two extremes of health.

◆

At Southwark Police Court, James Dalton, 40, described as a labourer, was charged (last Wednesday) before Mr Partridge, sitting Magistrate, with the wilful murder of Henry Johnson, thirty-two years of age, at No. 1, Henry street, Kent street, by beatin him on the head with a poker. Mr. Richard Clement Lucas, assistant house surgeon at Guy's Hospital, was examined, and explained that the reason why the deceased had not been admitted to the hospital as an in-patient was that his injuries were not considered serious enough to make it necessary to do so. He had made a *post-mortem* examination, and believed the cause of death to be blood poisoning, brought on by advanced disease of the kidneys. Mr. Partridge asked if the injuries were not the immediate cause of death. Mr. Lucas, after some hesitation, said they might, but he should not like to be positive about that. The diseased state of his kidneys was sufficient to account for the blood poisoning, from which disease he died. Dr. Hart said he had been a medical practitioner for fifteen years, and he had heard all the evidence. He had heard deceased had a disease in his kidneys in an advanced state, which produced blood poisoning, and that generally terminated fatally. He thought that the injuries inflicted were likely to have accelerated his death. The prisoner was committed to Newgate for trial.

Our Analytical Department.

COCOA.

REPORT ON THE QUALITY AT PRESENT SUPPLIED TO THE BRITISH MARKET.

(Continued from page 475.)

TABULAR SYNOPSIS OF THE MOST IMPORTANT COCOAS, &c., AS SUPPLIED TO THE CONSUMER.

No. of Sample.	Name.	Maker.	Price to Consumer.	Ash.	Fatty Matter.	Starch, other than Cocoa Starch.	Sugar.	Cocoa.
			Per pound.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
			s d					
2	"Finest Roasted Cocoa Nibs"	Messrs. J. and S. Fry, London	1 6	3	49	None	None	All cocoa
4	"Cadbury's Cocoa Essence"	Messrs. Cadbury Brothers, Birmingham	2 8	6	26	None	None	All cocoa
6	"Epps' Prepared Cocoa"	Messrs. James Epps and Co., London	1 8	1·25	28	10½	33½	56
7	"Cadbury's Chocolate du Mexique"	Messrs. Cadbury Brothers, Birmingham	2 0			None	50	50
8	"Van Houten's Pure Soluble Cocoa"	H. Eschwege, London (Consignee)	3 6	9	30	None	None	All cocoa
9	"Cacao en Poudre"	M. Menier, Paris	2 6	5	48·5	None	None	All cocoa
10	"Dunn and Hewett's Iceland Moss Cocoa"	Messrs. Dunn and Hewett, London	1 4	2	23·5	20	32	48
14	"Caraccatina"	" " "	2 0	3	40	None	None	All cocoa
15	"Pure Granulated Cocoa"	Messrs. Handford and Davies, London	1 2	5	42	None	None	All cocoa
16	"Barry and Co.'s Prepared Cocoa"	Finsbury Steam Mills, London	1 0	3	25	13	35	52
17	"Collier and Sons' Original Patent Commercial Cocoa"	Messrs. Collier and Son, London	0 8	8	17	42	24	24
18	"Maizena Cocoa"	Messrs. Dunn and Hewett, London	1 0	2	17	33	33	34
19	"Maravilla Cocoa"	Messrs. Taylor Brothers, London	1 6	2·25	27	12	34	54
20	"National Cocoa"	Messrs. J. and S. Fry and Sons, London	1 0	2	20	22	38	40
21	"Improved Pearl Cocoa"	Messrs. Taylor Brothers, London	1 6	2	17	24½	42½	34
23	"Improved Homœopathic Cocoa"	Messrs. J. and S. Fry and Sons, London	1 4	2	25	25	25	50
24	"Caraccas Cocoa"	" " " "	1 4	2	27	14	32	54
25	"Fry's Iceland Moss"	" " " "	1 4	3·25	23	20	34	46
26	"Chocolat-Menier"	M. Menier, Noisiel, Paris	1 8	1	20	None	60	40
27	"Chocolatine" (*Coloured Wrapper*)	Messrs. A. Loewenthal, Breslau and London	5 0	6	30	None	None	All cocoa
28	"Chocolatine" (*White Wrapper*)	" " "	5 0	5	31	None	None	All cocoa
29	"Gatti's Chocolate"			2	20	10	50	40
30	"Vanilla Chocolate"	Messrs. J. and S. Fry and Sons, London				None	50	50

In the above calculation, we have allowed the manufacturer double the percentage of cocoa as being present for the cocoa butter found. The prices in the cases of Samples 4, 8, 20, 27, and 28 are taken from the cover of the packet, Messrs. Dunn and Hewett's and Messrs. J. and S. Fry and Sons' preparations from their published lists; the remainder were prices paid for them at respectable shops.

Before concluding, we think it necessary to take a retrospective view of the present supply of cocoa, presuming that the analyses include samples from all the manufacturers of importance.

Certain of these manufacturers claim, with a little show of reasoning, that the addition of starch and sugar is not an adulteration, if not put in in undue proportions. This point has already been partially considered. We maintain that, in spite of the custom of the trade, this is an adulteration unless specified on the cover of the package, as in Sample 18; and that, under any circumstance, it is a great mistake. A large amount of cocoa is now consumed medicinally—that is to say, because the consumers are *recommended to take it* by their medical attendant, they therefore persevere in its use irrespective of taste, on the same principle as they would take cod-liver oil.

The increase in the consumption would be quadrupled if, instead of a "soup," as Mr. Johnson appropriately terms it,* they could get a thin and refreshing infusion of the cocoa bean. The fact that the insoluble part of the bean is always suspended through the beverage is a point that will always militate more or less against cocoa with the public; but when we supplement this by a thick decoction of starch, we have evidently made a false move. Some years since the ground or made-up cocoas were almost entirely used. The consumption of the nibs is at present greatly on the increase. The addition of sugar to cocoa is simply absurd, except, of course, when made in the form of confections for eating, and was originally introduced to make a large profit, and is now evidently maintained by respectable houses, so as to enable them to compete with other manufacturers. We maintain that every respectable house should label such mixtures definitely as regards their contents, and should make a leading article which should be simply pure cocoa, with the amount of fat reduced. Such a cocoa will, with skimmed milk, make an excellent nutritious beverage, and the consumer can add *sugar to suit his own taste* at the rate of 4d. to 6d. per pound, without paying at the rate of 1s. to 1s. 6d. In concluding, we will say a few words upon the general quality. On looking at the reports of the outrageous adulterations that were carried on some years since in this trade, we see that the manufacture of this article must have wonderfully improved. The presence of brick-dust, ochre, Spanish brown, suet, and inferior or rotten cocoa are (with some few exceptions) things of the past; but most of the cocoas sold are extensively mixed with starch and sugar. Indeed, the great objection to the cocoas now sold is the exorbitant price that the consumer is called upon to pay, the finest Trinidad cocoa being priced on the wholesale lists at 1s. 1½d. per pound. In the whole thirty-two samples examined, only one was found to be mixed with mineral matter—*i.e.*, Collier's original patent commercial cocoa.

Of the thirty-two samples, nineteen may be said to be quite pure. Of these, nine are cocoas—viz., Messrs. A. Loewenthal's two specimens, "Cadbury's Cocoa Essence," "Van Houten's Pure Soluble Cocoa," Dunn and Hewett's

---

* Chemistry of Common Life, Vol. I., p. 219.

"Caraccatina," Dunn and Hewett's Maizena Cocoa, Cacao Fabrique de Chocolat-Menier, Handford and Davies' Pure Granulated Cocoa, Messrs. Fry and Sons' Cocoa Nibs.

The five first are concentrated cocoas, or cocoas in which the fat has been reduced—a most desirable form; but Messrs. A. Loewenthal's cocoas are too expensive to become popular with the general public. Messrs. Handford and Davies' preparation is granulated to a most desirable size, and is moreover moderate in price. Of the chocolates, those examined from the houses of Messrs. J. and S. Fry, London and Bristol, M. Menier, Paris, and Messrs. Cadbury Brothers, Birmingham, are pure*—that is to say, consist only of sugar and cocoa. It must be remembered, however, that many of these manufacturers send out an immense number of articles made up in different forms, and it is for this reason that we have been so particular about the name or heading of each article examined.

◆

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your answer to my letter of the 5th instant, in yesterday's publication, admits that Van Houten's cocoa is comparatively cheaper than the *adulterated* cocoas, but leaves the controversy exactly where it was relative to other *pure* cocoas at present in the market.

I have to say, however, that your reading of the advertisement is perfectly correct, for not only do I claim that Van Houten's is the *best*, but that it is the *cheapest*, cocoa in the market; and as you seem, at any rate as regards its cheapness, to have formed a different opinion, and one which you have published, I believe I am fully justified in insisting on seeing your adverse remark either corrected or conclusively proved to be right.

I am, Sir, yours faithfully,
H. ESCHWEGE.

6 and 7, Coleman street, London:
June 10, 1869.

⁂ A relative comparison of similar cocoas with Van Houten's did not in our opinion warrant the rather wholesale statement that was put forward by Mr. Eschwege, of its being the cheapest in the market; a statement that would be impossible to substantiate, without a perfect knowledge of every cocoa in the market. We have since examined Van Houten's cocoa against the first similar one in our list, Messrs. Cadbury Brothers' Cocoa-Essence. Both examinations were from fresh samples procured for the purpose.

VAN HOUTEN'S SOLUBLE COCOA.

Fat present	30·5 per cent.
Moisture	3·5 „
Insoluble matter in cold water (including cocoa-starch) . .	45·25 „

CADBURY'S COCOA-ESSENCE.

Fat present	29·5 per cent.
Moisture	0·5 „
Insoluble matter in cold water .	44·0 „

Price per pound in 4oz. packages, 4s.; price per pound in 3oz. packages, 2s. 8d.; price per pound in 1oz. packages, 3s. 6d.

The above speaks for itself, and requires hardly any comment on our part. Taking into consideration the extra amount of moisture present in Cadbury's Cocoa, these preparations may be considered as almost identical in composition. Mr. Eschwege has informed us, in a letter dated June 14th, 1869, that he supplies charities and public institutions at 2s. 3d. per pound; but had we taken this price into consideration, there would have been some foundation for Mr. Eschwege's claim. All our calculations were based upon the published prices.

Again, although the concentrated cocoas may be more desirable preparations, there are some authorities who would prefer cocoa in its integrity; compared to such preparations, an extra manufacturing process for the extraction of the fat must entail extra cost; and it becomes evident that, *cœteris paribus*, such cocoas cannot be the cheapest in the market. If it were not out of respect for the excellent quality of Van Houten's preparation, we should have declined to enter into this controversy.

◆

"IS SILVER AN OXIDIZABLE METAL?"

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I see under the head of "Our Analytical Department," at page 455 of your issue of 2nd June inst., the following: "Now, if we take any moderately oxidizable metal, such as lead, *silver*, &c., and rub its surface with a little cotton-wool and oil, we shall find that the wool is covered with a black substance, simply because the metal is covered with an extremely minute film of *oxide*, which is mechanically rubbed off by the wool. Platinum, or gold, or unoxidizable metals do not give this result." Now, sir, *silver* is an *unoxidizable metal* under any temperature, and yet it does give "this result" when rubbed with greasy cotton-wool, particularly after exposure to the air of one of the manufacturing districts of England. What is this "*black substance*" rubbed off silver under these circumstances? Not a "minute film of oxide," but sometimes (as anyone like myself, having a weakness for silver-headed sticks, knows very well) a pretty thick film of "sulphuret," or "sulphide," as it is now called, of silver. Silver has been kept fused, in a glass-house furnace, constantly for weeks, without a particle of oxide being found, although freely exposed to the air all that time. The *Chemistry* of your "*Analytical Department*" should be above suspicion.

I remain, Sir, yours truly,
JOHN WOODS BECK, M.D.

⁂ DR. J. BECK's objections amount simply to a quibble outside the merits or objects of the report, in which "oxidizable" is used in the sense of atmospheric tarnishing, and "oxidized silver" has become a conventional term used by art workers in this very metal to specify tarnished silver. No one who has seen the action of nitric acid upon silver would object to the expression "moderately oxidizable metal" applied to that substance from a chemical point of view. J. W. Beck is right in attributing the tarnishing of silver in towns *mainly* to sulphur, but is wrong in the remainder of his statements. There is not the slightest analogy between "silver fused in a glass-house furnace" and silver subjected at ordinary temperatures to the influence of a moist atmosphere.

Again, sulphide of silver, at the temperature of a glass-house furnace, would be slowly but perfectly decomposed (rapidly in the presence of hydrogen), and, on the other side, it is said on good authority that silver loses from oxide being found in the process of cupellation.

Again, silver reduced from the chloride, and cleaned by boiling with cyanide of potassium, will in a few days give the black stains on rubbing with cotton-wool and oil; although kept under a vessel containing air chemically free from sulphur, alloyed silver gives this reaction more decidedly.

---

* The sugar in the interior of Messrs. Cadbury's chocolate creams is glucose, or fruit sugar; it is not the ordinary cane sugar.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 23, 1869.

THE trade instincts of the *Lancet* have once more induced it to overstep the limits of ordinary decency, and exhibit to the outer world the completeness with which its power is prostituted. Touch some men's pockets, and you find the only souls they have, and so it seems to be with the presiding genus at Bedford street. The last little conspiracy was so patent that we thought it well to let it pass, but again and again our purblind contemporary returns to the charge until silence must once more be broken. Time after time has the *Lancet* issued threats against medical authors who dared to advertise their works in the *Times.* Many honest men and true have long felt that a certain kind of publicity is not only unnecessary for medical works, but that it appeals to the public as distinguished from the profession, and we have, as individuals, refused to advertise our own books in the *Times* on this account. We have not, however, attempted to impose on others our views; still less have we attacked individuals for any practice we follow, as the *Lancet* has lately done. That journal has so long addicted itself to libel those who differ from it, that no wonder, even in this instance, it has maligned by name a gentleman far superior in social and professional position to any of its weekly scribes.

In its Number of May 29, it signalled out Dr. Fuller, of St. George's Hospital, as one who had disregarded its warnings; and in its last number (June 19) impudently assumes that he is now terrified into submission. "We are happy to note," says the writer, "that our last extreme measure has produced the desired effect."

Now, on this point we wish to put a question which we defy our contemporary to answer. Was not its editor told in the public streets a few days before the appearance of the attack on Dr. Fuller, that his order for advertising was on the point of expiring? If so, it were indeed easy to make believe in the efficacy of its rebuke. But there is a much more serious side to this question; and, as our contemporary will not let it rest, we shall not shrink from examining it. Is not the whole agitation a mere trade trick? The *Lancet* prates of professional honour, and drags it in the dust. Conscious of its waning influence, it vents its spite on all who do not help to fill its coffers. It sees men advertise in the *Times,* and it longs for the money to be spent in its own columns. Advertise in the *Lancet* and all is well, though your book may not sell; try the *Times,* and it is unprofessional; and the *Lancet,* in its jealousy for its profits, will pillory you. Nor is this the worst feature of the conspiracy. The *Lancet* has laid itself open to the simple retort, *tu quoque.* While assuming a pharisaical purity, it is guilty of all it imputes to those customers who have left it for an opposition shop. Well might Dr. Fuller and the other offenders exclaim, "First cast the beam out of thine own eye;" well may any one thus attacked say to the assailant, "First wash your own hands, for, see, there's dirt upon them." This we proceed to show for the benefit of all who despise hypocrisy. On the very same day on which the *Lancet* denounced Dr. Fuller for advertising his book in the *Times,* there appeared in the miscellaneous column of that newspaper the following announcements :—

MR. BRODHURST on DISTORTIONS of the TRUNK and NECK.—See the LANCET of this day (Saturday), May 29. Price 7d.; stamped 8d.

MR. BICKERSTETH on the ANTISEPTIC TREATMENT of WOUNDS.—See the LANCET of this day (Saturday), May 29. Price 7d.; stamped 8d.

DR. PAYNE on DRUG ACTION.—See the LANCET of this day (Saturday), May 29. Price 7d.; stamped 8d.

THE DISTRICT PAUPER SCHOOL at HANWELL. See the LANCET of this day (Saturday), May 29. Price 7d.; stamped 8d.

VACCINATION direct from the HEIFER.—See the LANCET of this day (Saturday), May 29. Price 7d.; stamped 8d.

THE METROPOLITAN CATTLE-MARKET.—See the LANCET of this day (Saturday), May 29. Price 7d.; stamped 8d.

ON the PRODUCTION of FALSETTO NOTES—Influence of Weather on Health—Soldiers' Night Duty—Gratitude—A Contemptuous Judge—Wealthy Hospital Patients, &c.—See the LANCET of this day (Saturday), May 29. Price 7d.; stamped 8d.

THE LANCET of this day (Saturday), May 29, contains:—Original Articles, a Mirror of the Practice of Medicine and Surgery in the London Hospitals, Reports of the Meetings of the Medical Societies, Reviews, Leading Articles, Annotations and Correspondence on Current Medical Topics. Price 7d.; stamped 8d. Office, 423, Strand; and of all booksellers and news agents.

We felt strongly at the time that such conduct as this ought to be exposed, and hoped some other hand than ours would vindicate justice. Yet, as no one else will do so, and as the *Lancet* has again returned to the charge, we will no longer withhold our protest; and we call upon all who love justice, as well as upon all who have expressed their condemnation in so many recent professional assemblies, to repudiate a morality which attempts to injure a medical man for doing what the *Lancet* has done week after week for so many years. No grosser attempt to force cash into its own till has ever been made by any paper. Look at the last number, and what do we find? The would-be regulator of medical advertisements heaps upon authors fresh scandalous charges, the foundations for which we challenge it to produce, and then proceeds to lay down four rules, as to advertising medical works in non-medical journals. Unfortunately, these rules have never been observed by those who thus lay them down.

We extract them for the edification of those who would like to know the drift of them :—

> "1st. No work should be advertised with the author's name and titles placed before the title of the book itself.
>
> "2nd. No review or opinion of the value of the work or the treatment recommended should be appended to the advertisement.
>
> "3rd. The work should be advertised by the publisher with his other works, and never in the column devoted to quackery.
>
> "4th. The frequency of the advertisement should be strictly limited to such publicity as a medical publisher would afford a medical work which was his *own* property for the purposes of *bona-fide* sale."

Now, no one can for a moment pretend that these rules have been observed in the weekly advertisements of the *Lancet*. Take the *eight* separate ones we have quoted above. The names of three authors are, in violation of the rule, placed before the titles of their works ; but then this is for the benefit of the next phrase, "see the *Lancet*," or are we to presume the authors pay ? or is this advertisement in the *Times* the meal or malt with which the *Lancet* pays its contributors ? Again, the *Lancet's* advertisements constantly break the rule as to the column in which they appear. We do not blame our contemporary for the position in which its announcements are placed, for the *Times* will not be dictated to as to its own business. Indeed, the sole reason of many for giving a large publisher all their advertising is, that thus they do not appear in equivocal company ; but then how few publishers can afford to take a whole column of the *Times* at once, and how few authors can afford or wish to pay for that luxury ! But, after all, an indifferent medical book is perhaps as good company as the *London Journal*, with which our wrathful medical contemporary is so often in juxtaposition. Once more, as to the last rule. Can anyone say that the above *eight* advertisements in one column are the measure of necessity for disposing of the copies of the *Lancet* ? Do they appeal to the profession or the public ? If all this parade is right for the *Lancet*, why attack Dr. Fuller, whose announcements are innocence itself compared to these ? There is no more barefaced effrontery than the constant advertisements of the *Lancet* in the very medium in which it forbids medical authors to advertise.

It is not now and then that these repetitions of "*see Lancet*" appear. Every week the same method is adopted, and has been for years. Here is a confession of faith put forth by the *Lancet* in a former article, and repeated again last Saturday :—

> "The object of advertising is to attract the especial attention of the general public. The means of attraction consist in putting forth statements which lead those who read them to believe that the advertiser [journal advertised ?] is in some way or other superior to his fellows [its contemporaries ?], and therefore a person [journal ?] to be especially patronised. Where trumpeting is in vogue, the loudest trumpeter has the best chance of being heard [eight advertisements are therefore necessary for one number of the *Lancet*]. When everybody is saying something to recommend himself, it is necessary to say very startling things to invite notice [*e.g.*, *see Lancet* over and over again]. An advertisement affords no test of a man's ability, of his truthfulness, or of his honour [or a journal's ?]. It levels rogues, fools, and sages" [to the level of the *Lancet* ?].

Our readers will see that we attempt to place no unfair meaning on the words we have quoted. So palpably do they condemn the practice that has been adopted in spite of the rules, that perhaps our contemporary will now be able to see the force of its own observations, and, in token of penitence, will tell us how many years it has carried on this "unprofessional advertising." That it has gone on after denouncing others we have shown, and may add proof to proof. Here is its own announcements in the *Times* of last Saturday week :—

DR. CLIFFORD ALLBUTT on PARACENTESIS PERICARDII.—See the LANCET of this day (Saturday), June 12th. Price 7d. ; stamped 8d.

PROFESSOR SYME on the REFORM of MEDICAL EDUCATION.—See the LANCET of this day (Saturday), June 12th. Price 7d. ; stamped 8d.

DR. ELAM on MEDICINE, DISEASE, and DEATH.—See the LANCET of this day (Saturday), June 12th. Price 7d. ; stamped 8d.

MR. BICKERSTETH on the ANTISEPTIC TREATMENT of WOUNDS.—See the LANCET of this day (Saturday), June 12th. Price 7d. ; stamped 8d.

DR. ROBINSON on ACUTE RHEUMATISM.—See the LANCET of this day (Saturday), June 12th. Price 7d. ; stamped 8d.

MR. BLANCHARD JERROLD on the SICK POOR of PARIS.—See the LANCET of this day (Saturday), June 12th. Price 7d. ; stamped 8d.

TYPHOID FEVER at the ORPHAN ASYLUM at BEDDINGTON.—See the LANCET of this day (Saturday), June 12th. Price 7d. ; stamped 8d.

THE ELECTION of COUNCILLORS at the COLLEGE of SURGEONS.—See the LANCET of this day (Saturday), June 12th. Price 7d. ; stamped 8d.

THE LANCET of this day (Saturday), June 12th, contains :—A Mirror of the Practice of Medicine and Surgery in the London Hospitals—Reports of the Meetings of the Medical Societies—Reviews—Leading Articles—Annotations—Special Articles and Correspondence on Current Medical Topics. Price 7d. ; stamped 8d. Office, 423, Strand ; and of all booksellers and news agents.

It will be seen from the above that six gentlemen's names are placed before their works in order to puff the paper that is so shocked at an individual doing the same, and no less than nine distinct advertisements in a non-medical paper are the measure of the publicity necessary to get off the copies of a professedly medical journal.

Surely the object of such advertising as this is, in the *Lancet's* own words, "to attract the especial attention of the *general public*," not that of the members of the profession, to whom it pretends to address itself, and who will henceforth know the value of its advocacy of professional conduct. Shall we stop, lest the reader exclaim, More than enough—*usque ad nauseam !* One more sample, then, and we have done. Here is the announcement in last Saturday's *Times*, June 19, the day on which the attack on medical authors was renewed :—

MR. BRODHURST on DISTORTIONS of the NECK.—See the LANCET of this day (Saturday), June 19th. Price 7d. ; stamped 8d.

DR. D. SMITH on the STRUCTURE of the ADULT HUMAN VITREOUS HUMOUR.—See the LANCET of this day (Saturday), June 19th. Price 7d. ; stamped 8d.

DR. SPENDER on SYPHILIS.—See the LANCET of this day (Saturday), June 19th. Price 7d. ; stamped 8d.

DR. GOURLEY on RETENTION.—See the LANCET of this day (Saturday), June 19th. Price 7d. ; stamped 8d.

DR. M. EVANS on POISONING by NICOTINA.—See the LANCET of this day (Saturday), June 19th. Price 7d. ; stamped 8d.

THE ARRIS and GALL LECTURES at the Royal College of Surgeons.—See the LANCET of this day (Saturday), June 19th. Price 7d. ; stamped 8d.

THE MORTALITY of BRIGHTON.—See the LANCET of this day (Saturday), June 19th. Price 7d. ; stamped 8d.

VACCINATION DIRECT from the HEIFER.—See the LANCET of this day (Saturday), June 19th. Price 7d.; stamped 8d.

THE LANCET of this day (Saturday), June 19th, contains:—A Mirror of the Practice of Medicine and Surgery in the London Hospitals—Reports of the Meetings of the Medical Societies—Reviews—Leading Articles—Annotations—Special Articles and Correspondence on Current Medical Topics, &c. Price 7d.; stamped 8d.—Office, 423, Strand; and of all booksellers and news agents.

Observe, five men's names before their works, and nine distinct advertisements of the last number of the *Lancet*, in which honest men are libelled for an alleged impropriety of one-ninth the extent.

◆

Notes on Current Topics.

Embalming.

A NEW process, which is indicated by the grandiloquent title of Nekrosozoic, has been recently made public in America, and since then introduced into London. Its object is the preservation of dead bodies, but for what length of time we are not informed. It consists simply in the washing of the body externally, and the injecting into the stomach and rectum of a fluid of which the composition is kept secret, and which is said to effect the preservation of the body for many months without the necessity of making any incision for the purposes of injection. The invention comes to us from America, accredited with the testimony of men of high scientific note, and their experience of its use places it beyond doubt that it to a certain extent effects all it proposes to do.

Mr. Delafield, Curator (Bellevue Hospital), and Mr. Wood, Professor of Operative Surgery, examined in April, 1868, the body of a woman which had been preserved for 103 days by the Nekrosozoic process.

There was no incision at any point by which any material could have been injected into the veins or arteries. He examined the brain, lungs, heart, abdominal viscera, and the muscles throughout the body. There was nowhere any sign of decomposition.

The skin and the muscles were not dried nor hardened. Even the fingers and toes were still soft and plump. The limbs could be easily flexed, as could also the fingers and toes. A portion of the muscles from the thigh was subjected to microscopical examination. There was no breaking down of the muscular fibres, which looked as if from a body not more than twenty-four hours dead.

Professors Doremus and Austin Flint also testify to the integrity of the structures several months after their embalming.

The body of the woman who died of pulmonary tuberculosis, on the 13th of February, was treated in this way, five days after her decease, and when examined on the 25th of April, more than two months having elapsed, was found in a complete state of preservation. Chemical tests demonstrated the presence of one of the prominent preservative agents in this embalming fluid—viz., carbolic or phenic acid in every portion of the system.

Its permeating power is so remarkable that injection through the circulatory system is not essential for impregnating the tissues to a sufficient degree for their preservation during a few weeks. The rigid scrutiny of the microscope revealed the minute tissues in an almost perfectly unchanged state.

Lastly, Professor Mott thinks that it far surpasses in efficacy any method heretofore adopted for the preservation of bodies.

Sudden Blanching of the Hair.

THIS moot question has been recently discussed by M. Pouchet in the *Avenir National*, and narrates the following anecdote:—

On the 19th of February Colonel Franks was engaged near the village of Chamba with a body of rebels, and many prisoners were taken; one of them, a Bengalee, aged about 54, was conducted before the authorities to undergo interrogations. "I had then," said Surgeon-Major Famy, "an opportunity of observing personally the following facts. The prisoner, for the first time, appeared to realise the danger of his situation when he found himself stripped and surrounded with soldiers. He trembled violently, terror and despair being depicted on his countenance; and, when replying to the questions addressed to him, he appeared absolutely stupified by fear. Then, under our eyes, and in the space of some half an hour, his hair, which we had seen to be of a brilliant black, became grey on every part of his head. The sergeant who had charge of the prisoner cried out, 'He is turning grey,' and called our attention to the singular phenomenon, of which I thus, with many other persons, was enabled to observe the completion through all its phases."

The Hospital Staff Remuneration Question.

REMUNERATION to the medical staff of the hospitals is a subject that still continues to be discussed by the press, and it is to be hoped that the subject may be thoroughly ventilated, and the "radical change" accomplished in it be again permitted to be in abeyance. In a late number of the *Birmingham Gazette* there appeared an article which bears very strongly on the point. Referring to the meeting called to discuss the question of establishing at West Bromwich an hospital, the article boldly slides into the question of Hospital Reform in the following fashion:—

> "It would be a difficult matter to urge substantial reasons why the members of the medical profession shall continue to be an exception to all other classes of men, and do an immense amount of public work for no remuneration whatever. By their own free will has the anomaly existed so long; but once they declared against it, the public have no right to exact the indefinite prolongation of a state of things equally opposed to common sense and to every rule of business. As for the credit derived from the work being a sufficient reward, it is well to bear in mind that every man, whether a banker or lawyer, a manufacturer or an artisan, seeks two kinds of reward for the investment of his capital and labour—reputation and payment. Twenty per cent. would be deemed dear profit if it entailed loss of character, and no amount of credit derived from the conduct of a transaction is held sufficient recompense, by business men, to the exclusion of tangible reward in the shape of money gain. To take the particular case of the West Bromwich Hospital. The architects entrusted with its erection doubtless hope thereby to increase their reputation; but no one supposes they will forego their commission for the honour of doing the work. Of course not; they are business men, and will expect to be paid. Why should

the surgeons be an exception? It is generally believed that hospital appointments in large cities bring indirect reward with consulting practice; but there is not much likelihood of that being the case in the towns of the Black Country, where, moreover, it is the practice for masters to employ field surgeons, and to pay professional men for attendance on the workmen injured in the pits and forges; on what principle is the duty henceforward to be discharged for nothing in the Hospital? As to the threat of introducing medical men from without to officer the new institution, it may be well to recall the case of the Birmingham General Dispensary. When its honorary staff resigned, the managers found that no professional man of repute would accept office without remuneration, and now the whole staff, resident and consultant, is paid. When the club surgeons of the town and district applied for higher rates, the endeavour to replace them by cheap outsiders proved instructive. In all callings men of damaged reputation may be found who will be thankful for a chance to earn a living on almost any terms; but character and proved skill always command a fair price, and it is not to be supposed that surgeons, any more than ironmasters or bankers, will undersell each other, when they conscientiously feel that they have claim to just remuneration."

The Dublin Hospitals.

On Saturday evening, at the Statistical Society, the Right Hon. Judge Longfield in the chair, Dr. Mapother read a paper, entitled "The Dublin Hospitals, their Grants and Governing Bodies." He dwelt at some length on the funds of these institutions, suggesting a more equable distribution of those from public sources, and stated that the increase which probably would be derived from the Church surplus was much needed. He urged the distribution of fever cases amongst all the hospitals, rather than their being treated in a separate institution. The modes of electing medical officers were described, those adopted in Jarvis street, Mercer's, City of Dublin, and Meath, namely the payment of a fixed or changeable sum, being severely censured. Legal opinions as to the validity of some recent appointments were read, and the author concluded by urging that the plan pursued in most London Hospitals should be copied, viz., election by governors on the recommendation of the medical staff.

Several leading members of the profession and members of hospital committees took part in the discussion, of which we shall publish a full report next week.

Health of Dublin.

In the Dublin Registration District the births registered during the week ending June 12th amounted to 183—92 boys and 91 girls. The average number in the corresponding week of the years 1864 to 1868 inclusive, was 185. The deaths registered during the week were 136—70 males and 57 females. The average number in the corresponding week of the previous five years was 145. Six deaths were ascribed to scarlet fever, being four less than the number registered during the week preceding. Four deaths from fever were registered, viz.:—one from typhus, and three from enteric or typhoid fever. The deaths of six children were referred to convulsions. Bronchitis caused twenty deaths, and pneumonia or inflammation of the lungs two. Six deaths resulted from apoplexy, and three from paralysis. Eight deaths were attributed to heart disease. Phthisis or pulmonary consumption proved fatal in twenty instances. Mesenteric disease and hydrocephalus, or water on the brain, each caused three deaths. Three accidental deaths were registered.

Scientific Evidence.

On Thursday an action in the Common Pleas, in which judgment was allowed by default, "Poole v. the Great Eastern Railway," was heard before Mr. Under Sheriff Burchell. Compensation was sought for injuries in a railway collision, and damages were laid at £1500. The noticeable feature of the case was that three medical witnesses on the plaintiff's behalf declared that he had received a concussion of the brain, and two surgeons for the company declared there was no such concussion, but only disease of the heart of long standing. Mr. Under Sheriff Burchell commented upon this extraordinary discrepancy, and advised the jury to consult their own common sense. The damages were assessed at £300.

Medical Excommunication.

The *Union Médicale* remarks in its last number on a Circular of the 7th of May, emanating from the Court of Rome, and sent to all the medical practitioners in the Holy City, and observes that it has given rise to much scandal in Italy.

"It has come to my knowledge," says the Cardinal Vicar who signs the document, "that many sick persons under medical treatment have recently passed *all' altra vitra* without religious consolation. For this reason, by authority and order of St. Peter, I am obliged to remind physicians and surgeons of the canonical laws relative to the administration of the sacraments to patients according to the third Constitution."

"No medical practitioner will be invested with the doctorat without having sworn to visit no patient, who, at the third visit, shall not have caused a confessor to be sent for, otherwise he incurs the *major excommunication*, besides the severest punishment which the Sovereign Pontiff or his local legates may inflict."

"The medical man is required, before any other duty, to persuade his patients to confess their sins, otherwise he is excluded from the Church."

"Every commentary," says the *Union Médicale*," is superfluous in respect of this literal translation. It shows too clearly that the Court of Rome is no longer of our age."

At the last meeting of the International Commission for the Cure of the Wounded on the Field of Battle, the most interesting manœuvres were executed of the Prussian army. The field was exactly counterfeited. Wounded and dead were there in abundance (apparently), and the whole system was in action—surgery, hospital corps, and ambulances. The wounded were brought in, the ambulances were equipped as in time of war, and the surgeons directed their attention to them and the patients so as to put to as effective proof as possible the efficiency of the sanitary arrangements. Each patient was cared for exactly as on the field of battle, and, it is possible, as one of the staff remarked, were noisier and more occupied in this affair than on the field of Koniggratz.

The *Gazette Médicale de Paris*, alluding to these movements, says:—"It is unnecessary to remark upon the value of such manœuvres, which exercise perfectly the medical service of the army, so that all shall be provided and prepared for the day of war. The Prussians, it is evident, attach extreme importance to all that concerns the care of the wounded; they have studied with care, and adopted all the improvements which have been introduced into the ambulance system; and in the last campaign the perfect organisation of the medical service was of enormous benefit to the army."

The Lords of the Admiralty, having had under their consideration the medical appointments in the establishments at home, have come to the conclusion that no advantage results to the public service through the retention during many consecutive years of the same appointments by the same individuals—a practice which prevents the officers in the service from obtaining their fair share of the best appointments at home—have decided that Dr. J. F. Charlton, and Mr. C. D. Steel, staff-surgeon, Portsmouth division, shall relinquish their appointments on the 31st of the present month. But their Lordships have notified that the claims of these officers for employment in future service at sea or on shore will receive the fullest consideration.

The Academy of Sciences of Paris held its annual public sitting on Monday week last, at the Palace of the Institute.

M. Villemin obtained a prize of 2,500f., and MM. Feltz, Flint, and Raciborski, were awarded honourable mention and 1,500f. for their contribution to medicine and surgery.

The Academy recompensed the remarkable researches of M. Villemin on the inoculation of tubercle, and on phthisis. The author had already announced this important fact last year, but the Commissioners had desired that further experiments should be made to ensure that its accuracy should be incontestable.

If a subcutaneous opening be made in the ear of a rabbit and introduce a morsel as large as a pin's head of tuberculous matter taken from man or cow, a local deposit of tubercle is at once developed in the animal. The sympathetic ganglia communicating with the wound are impregnated with nodules of tubercle. The results of this method of inoculation have been examined by MM. Andu, Bouilland, Clognet, Longet, Nélaton, and Langier.

From the fact of the inoculation the virulence of tuberculosis may be concluded. Then, if it be inoculable and virulent, it is necessarily contagious.

Being inoculable from men to animals it will be so without doubt from man to man. It will be for the future to decide in what special conditions cohabitation may render the disease transmissable.

SUCCESSFUL OVARIOTOMY IN A CHILD, TWELVE AND A HALF YEARS OF AGE.

At the meeting of the Société Impériale de Chirurgie, May 26, M. Jouon, of Nantes, related an extraordinary case of ovarian tumour successfully operated on, which is reported in the *Union Médicale*. A little girl, twelve and a half years old, had suffered for eighteen months from a very large abdominal tumour, which had become of such a size as to have reduced the girl to an extreme state of exhaustion. The belly presented the appearance of a twin gestation at the extreme period; it was dense and fluctuating everywhere but at the left hypochondriac region, where the intestines were lodged. The age of the child, the absence of all signs of puberty, and the impossibility of isolating the liver, made the diagnosis of ovarian tumour doubtful. Recamier's method of opening the cyst by caustic was adopted, and a large quantity of very albuminous fluid made its escape; a sound was introduced, and a multilocular sac was found, proving the existence of ovarian cysts.

On the 15th March ovariotomy was performed. There were strong adhesions to the abdominal wall where the caustic had been applied; several punctures with a large trocar were unsuccessfully made into the sac; during the effort of extraction, two large cysts at the back of the tumour gave way; the entire mass was extracted, leaving a long pedicle from the left ligament; a clamp was applied, and the pedicle divided. The epiploon required two ligatures; the closing suture embraced a portion of peritoneum on each side; but coaptation was difficult, owing to the thickness of the membrane. Frequent vomiting occurred during the first thirty-six hours, but complete cure was finally accomplished by second intention in forty-six days. The tumour consisted of three large cysts, and the total weight, solid and liquid, equalled twenty-six pounds (French).

CREOSOTE IN THE TREATMENT OF TYPHOID FEVER.

M. G. Pecholier, of Montpelier, has lately made an extensive trial of this remedy in cases of typhoid fever. He attributes the disease to a ferment in the blood, and that the *origo mali* consists of the "modification produced in the animal economy by the depraved blood, and the reaction of the animal economy against this cause."

"From the recognised influence of creosote in destroying organic ferments, he determined on a fair trial of its power in destroying what he terms *typhoid ferments*. The *Bulletin de Thérapeutique* reports that, experimenting on sixty cases of typhoid at St. Eloi Hospital, he gave daily three drops of creosote by the mouth, and an enema of three to five drops, his object being to keep the blood under the creosotic influence. No inconvenience was caused by the administration, and the result was—that in the cases where the disease was in an advanced condition, as anticipated, little or no effect was produced; but in those where the patients were got into hospital in the earlier stage, the effect was to diminish very considerably the duration and also the intensity of the disease; and he concludes that, without doubt, the early administration of creosote has the most powerful influence on the course of the fever."

It is also suggested that, during fever epidemics, creosote should be used as a prophylactic in hospitals or large institutions. Though we may doubt the power of this remedy and in such doses in our Irish typhoid, we think the subject worth consideration and fair trial.

POISONING BY PETROLEUM.

A case of this accident is reported in the *Journal de Chimie Médicale*. This accident is so far rare that the following instance is remarkable, specially from the nature of the tetanic symptoms. A man drank by mistake some rectified petroleum, and almost immediately he got irritation of the throat, violent colicky pains, and desire to vomit, followed directly afterwards by most severe tetanic spasms. He now suffered dreadfully, and had spastic contractions, accompanied by loud and urgent cries of agony. In ten minutes these symptoms again occurred with still greater urgency.

During the spasms he could not swallow even liquids, and he made most violent attempts at vomiting. In the brief intervals of calm, Dr. Humbert administered an emetico-cathartic mixture, and the patient shortly vomited freely material smelling strongly of petroleum.

Magnesia was then freely administered, and in three hours the chief urgency of the symptoms had passed away. The convulsions had been most severe, and the tetanic contraction so strong as to require the assistance of five or six men to restrain the patient. The only after consequences were, inflammation of the throat and bowels, and an ophthalmia caused by the vapour of the petroleum.

POISONING BY CAMPHOR.

A CASE reported in the *Journal de Chimie* has lately been laid before the Society of Medicine and Pharmacy of Grenoble, of a remarkably small quantity of camphor, used as an enema, causing most urgent symptoms. "A child of three and a half years, suffering from mild fever, had an enema of five grammes of camphor, suspended in yolk of egg, administered to it. This was shortly followed by lividity of the face, vomiting, cold sweat, and convulsions, accompanied directly afterwards by insensibility and retention of urine. The child's life was in imminent danger for ten hours. Coffee was given as an antidote, and recovery gradually took place."

◆

Foreign Medical Literature.

A CASE OF ANEURISM OF THE ARCH OF THE AORTA CURED BY ACETATE OF LEAD.

(Communicated by S. HOEGH, District Physician.)

Translated from the *Norsk Magazin for Lægevidenskaben*, xxii. Bind, 6 Hefte, 1868, p. 348, by WILLIAM DANIEL MOORE, M.D., Dub. et Cantab., M.R.I.A., L.K.Q.C.P.I., Honorary Fellow of the Norwegian Medical Society.

OLDER writers, as Panaroli and Albertini, have, according to Lebert (in Virchow's *Pathologie*), communicated cured cases of aneurism of the arch of the aorta; and, at a later period, Cruveilhier and Rokitansky have, with certainty, anatomically demonstrated the same; and, finally Legroux and Dusol have recorded three cases in which the diagnosis, according to Lebert, was indubitable, and which was cured by acetate of lead.

The case of this nature which I am about to relate is, therefore, not unprecedented; but the prognosis must in general be said to be so unconditionally bad, and the fatal result of such cases to be so predominatingly usual, that recovery is to be looked upon as an extremely rare exception. I believe, therefore, that the following history ought not to be held back, defective as in other respects it may be.

The girl, Martine Lundberg, applied to me first in 1858, chiefly on account of headache, from which she was suffering. She was then eighteen years of age, above the middle height, heavy in her limbs, very plump, rather dull in appearance and slow in her movements. She was of pale and well marked chlorotic aspect. She complained of periodical and violent headache, recurring about every eighth day. It is felt chiefly in the forehead, and is so violent that during the attacks she can do nothing, but must go to bed. It begins always in the forenoon and lasts until late in the evening, when she succeeds in falling asleep; on the following day she is rather confused in the head and dull, but feels no pain. During the attacks she is paler than usual. In other respects she is on the whole well, has a good appetite and good digestion, bowels regular, complains only of being very heavy and sluggish in her limbs, and of being easily put out of breath by exercise, though not to any great degree. She began to menstruate three years ago; the catamenia are copious and fortnightly, lasting two days at a time. She has been subject to headache since she was twelve years of age, and in a steadily increasing degree. On examining her chest, which it was rather difficult to accomplish with accuracy, on account of the great fulness of her breasts, I could not discover any abnormity either in the lungs or in the heart, whose sounds, dulness on percussion, and impulse, appeared to me to be quite regular. In the carotids a feeble murmur was heard on both sides. The pulse was rather slow, full, and soft. Everything else was normal.

I consider that she was suffering from chlorosis, with which the headache was not improbably connected, and I prescribed chalybeates and bitters, without obtaining any other result than that her complexion became less pale. The headache with its weekly attacks continued just as before. Subsequently, I tried many of the remedies recommended for hemicrania, as coffee, quinia, valerian, naphtha, inunction on the forehead of belladonna ointment, and chloroform liniment, cold applications to the head, warm footbaths, &c., without more advantage. The remedy from which at last she found the greatest benefit was five drachms of spirit of nitrous ether with three of laudanum, in doses of 20 drops four times a day during the attacks. By this the attacks were relieved and considerably shortened; indeed it sometimes happened that they were at once arrested.

In the following years down to 1863 she consulted me occasionally at long intervals, partly on account of the headache, which continued to manifest itself, but gradually passed into a fortnightly type, sometimes occurring only every three weeks; partly on account of the profuse, weakening menstruation occurring every fourteenth day. She was, moreover, inclined to difficulty of breathing on bodily exertion, and suffered occasionally from cough with scanty mucous expectoration. A couple of times I examined her chest without finding more than I did on the first occasion. Her pale complexion gradually assumed more and more of a dirty yellowish tint; she was plump, with large breasts and pendent abdomen. I made her again use iron, quinia, and valerian, and advised a change in her mode of living, urging her to discontinue weaving, which she was usually engaged in, and to occupy herself more in easy outdoor work.

In April, 1863, a prominence was discovered in the region around the sternal extremity of the left clavicle, which, she said, she had observed a couple of months before. In the neck to the left, and over the sternal end of the clavicle, under the sterno-cleido-mastoid muscle, a roundish swelling of about three quarters of an inch in diameter was seen, projecting in the neck about two lines above the normal level. The sternal extremity of the clavicle seemed perhaps to be slightly pushed forward, which was also distinctly the case with the space between the clavicle and the first rib in toward the sternum. The projection in the neck pulsated strongly, rising, during the pulsation, by at least a line, and becoming, at the same time, extended in breadth. Beneath the clavicle the pulsation was scarcely perceptible. In the neck the pulsation takes place in two periods, which follow immediately one another, the first which is almost a direct sequel of the heart's systole, or about isochronous therewith, is violent, sudden, always equally visible, always equally prominent; the second, occurring about simultaneously with the cardiac diastole, or immediately after it, is feeble, vibrating, often scarcely visible. On grasping the tumour with the points of the fingers, it is felt to be round or conical, passing with its broader base downwards, backwards and to the left beneath the sternal end of the clavicle, in the first period the pulsation is felt striking strongly against the points of the fingers, and both rising and proceeding in a transverse direction. In the second period it is felt merely as a vibration or fremissement in the tumour. The surface of the tumour is quite smooth to the touch; the tumour is tolerably firm, tense, though in part elastic and half fluctuating. Moderate pressure] (greater force I would not venture to employ) causes the tumour to diminish a little, at all events, so much as to be quite evident. On percussion, a dull sound was elicited over the tumour and over the inner fourth of the clavicle, and immediately under the latter; from the upper edge of the first rib to directly under the inferior edge of the fourth rib, I obtained everywhere a clear, sonorous sound. The cardiac dulness extended in breadth from half an inch in on the left margin of the sternum to about one inch beyond the nipple. The examination was, however, extremely difficult on account of the hypertrophied breasts. Elsewhere over the whole chest the sound on percussion was normally sonorous. The heart's impulse could scarcely be felt on account of the large mammæ; on auscultation both cardiac sounds were pure, normal, although perhaps rather weak. On following the course of the aorta with the stethoscope no accessory sound was heard, until the instrument reached the space between the second and first ribs, where a gradually increasing murmur commenced, which was strongest directly over the tumour. This murmur was here constantly heard, but with greatly increased intensity before each cardiac systole, and then it was mixed with a distinct bellows sound, which was sometimes slightly sibillant. This bellows sound was heard immediately after the systole, lasted a short time, and was then succeeded by the uniform murmur. In the left carotid, and about the middle of the neck, the same sound, gradually diminishing, can be followed with the stethoscope. In the right carotid no murmur was audible. Both radial pulses were the same, full, soft, ranging from 65 to 70. The respiratory murmur in both lungs was normal. There was no increase of hepatic dulness on percussion. The urine was free from any trace of albumen. The complexion and the colour of the skin in general was pale, with a yellowish, half-dirty tint. She complained of a constant, extremely disagreeable and distressing feeling of palpitation in the tumour, which increases greatly when she exerts herself in the slightest degree with work, in which case she has also, in addition to the palpitation, a half suffocating sensation of oppression. Sometimes she complained of some cough, accompanied with a very scanty mucous expectoration. Her appetite is very good; bowels regular; catamania still (though less) copious, occurring every fortnight. Other functions normal.

She had latterly been occupied chiefly in going into the fields to milk cows twice a day — a very laborious occupation. She was not aware of any more likely cause of the occurrence of the swelling.

I forbad all laborious occupations, and ordered four grains of acetate of lead morning and evening, increasing the quantity by two grains every eighth day.

When she had reached ten grains, she was obliged to discontinue the use of the medicine on account of the occurrence of violent colicky pains, occasionally accompanied with fainting, great languor, loss of appetite, and constipation: on all her teeth was seen a leaden grey coating, about half a line in breadth along the gums, which were swollen, of a dirty bluish colour, readily bleeding when touched. She looked, on the whole, scorbutic and very wretched. She had, however, after eight days' use of the acetate of lead, distinctly remarked that the palpitation in the tumour had somewhat diminished. She got, morning and evening, a teaspoonful of a mixture of equal parts of sulphate of magnesia and sublimed sulphur, and she also took of one part of tincture of perchloride of iron, with two of essence of cinchona, forty drops three times a day. In three or four weeks the toxical phenomena had entirely vanished, and her appearance was, in many respects, improved.

I did not now see her again until October, 1863. The tumour had increased in size; the symptoms were, in other respects the same. She once more used the acetate of lead, until the same phenomena occurred, after about the same lapse of time, with such violence that its use had to be discontinued. But again she felt distinctly that the disagreeable palpitation in the tumour diminished under its use; and that, in particular, the half suffocating sensation did not at all occur during its employment. But the symptoms became again aggravated, when some time had elapsed since the use of the lead.

In 1864 and 1865 I neither saw nor heard from her. She was, in fact, in another and distant locality, where she had no medical assistance.

In the autumn of 1866 she consulted me again. The tumour was considerably larger, and now projected in the left side of the neck, like the half of a pigeon's egg set upon end. The physical signs were essentially the same as before, only there were stronger pulsation, a louder murmur, and slightly increased dulness on percussion, on and directly beneath the clavicle. At the same time I thought I found some dulness on percussion over the whole of the upper part of the left lung, with some slight feebleness of respiration. The cardiac sounds were normal. The sallow tint had increased; her condition was, on the whole, not so good. Headache every third week — sometimes every fortnight. Catamenia not very abundant. Appetite tolerable. Bowels regular.

She got, although much against her will, as she had a great dread of the effects of lead poisoning, two grains of acetate of lead morning and evening, one grain being added to the dose every eighth day. After four weeks' use of the remedy she had again toxical symptoms, which obliged her to lay aside the acetate, and to resume the sulphate of magnesia with sulphur. The symptoms of poisoning having disappeared at the end of a month, and the palpitation in the tumour, which, during the use of the acetate, and for some time after had again evidently diminished, having again begun to manifest itself with its former violence, I once more gave her, as she looked extremely reduced and miserable, iron and cinchona, as well as, morning and evening, half a grain of digitalis with four grains of nitre and one-sixth of a grain of opium. Her appearance now improved considerably, but the tumour and its attendant subjective inconvenience steadily, though slowly, increased.

In May, 1867, the tumour projected much like a hen's egg cut across, the sterno-cleido mastoid muscle being tightly stretched over it. The arching forward of the space directly beneath the clavicle was, however, scarcely perceptible. The pulsation was stronger and extremely painful to her. Occasionally she was attacked with short, but complete, attacks of suffocation, during which her face became quite of a bluish red. During such an attack I once bled her, after which some alleviation (less palpitation in the tumour and diminution of the feeling of suffocation) took place during eight days; while, on the other hand, the general sallowness and sensation of languor with the attacks of headache became greater, so that I did not think it advisable to repeat the venesection. The cardiac sounds were again examined, without any irregularities being detected. As the acetate of lead had previously proved capable of restraining the symptoms, and as I had no doubt that I had to deal with an aneurism, and as acetate of lead was the only remedy in which I had, under that supposition, any, though only extremely slight, confidence, I induced her, after much discussion, to recommence its use, on which, for the reason already stated, she entered with great reluctance. I gave her again four grains morning and evening, but did not allow her to increase the dose. She now continued the medicine for eight weeks, during which time a decided diminution in the subjective sensations was observed, while on outward investigation the pulsation also felt much weaker, though the size of the aneurism continued the same. She again suffered from colic, fainting fits, loss of appetite, constipation, and presented a bluish line on the gums. She got a teaspoonful of sublimed sulphur morning and evening, with tincture of digitalis and tincture of perchloride of iron.

I then set out for Paris, and hearing on my return a report that she was cured, I sent her a message requesting her to call on me that I might investigate the state of the case. In November, 1867, she presented herself, and I then found that *all signs of aneurism had disappeared.* No trace of prominence was visible, either in the neck or below it, no pulsation was seen, nor could anything abnormal be felt when the finger was deeply pressed in. The sound on percussion was everywhere normal, and auscultation gave no sign of aneurism or any disease in the chest. She felt fresh and well, the sallow tint had disappeared, and was replaced by a somewhat pale, but not abnormal, complexion. The headache was, when on some occasions it was felt, very slight, and no longer prevented her being up and attending to her business. She had no dyspnœa, so far as she could judge, not having as yet ventured on any bodily exertion. Her functions were otherwise regular. She said that in July she had, of her own accord, gone through another course of lead on the same plan as on the last occasion; it had lasted six weeks without producing symptoms of poisoning. Meanwhile the tumour had become steadily quieter, and had diminished in size, so that, since the beginning of September, she had no longer perceived it. Since that time her general health had constantly improved.

As I write this (in February, 1868), I have just seen her, and found her, with the exception of an occasional headache, quite well, notwithstanding that she has latterly taken part in any work that offered itself.

The questions which, in the first instance, suggest themselves in the foregoing case may be considered under three heads—1, whether the diagnosis was correct; 2, whether the aneurism, supposing the diagnosis to be correct, was permanently cured; and, 3, whether the treatment adopted—that is, the use of the acetate of lead—was in such case the cause of the favourable result.

1. I cannot see why it should be supposed that the diagnosis was incorrect—that is, so far as it referred to an aneurism of one of the great thoracic arteries—because whether the aneurism was, as I am most inclined to believe, on the arch of the aorta, and not on the subclavian or carotid, may perhaps be subject to doubt. But this latter question seems to me to be of less importance;* the principal point must be, was there aneurism or not? The diagnosis of aneurisms in the cavity of the thorax may indeed often be extremely difficult, when,

---

* Brandes, "sp. Path. og Ther." II., 204, says: "The special diagnosis, in what part of the thoracic aorta the aneurism has formed, is indeed treated of by various authors, but seems to me to be without practical value, as it may be attended with the same results."

for example, there is no projection discoverable (indeed, even with a projection, mistakes may occur, as in Crisp's case, where a pulsating mediastinal abscess, which subsequently opened, led him to diagnose an aneurism); but when a pulsating tumour, which presents all the signs of aneurism, exists, and when this tumour, as in the above case, continues and increases steadily for years, without our being able otherwise to explain its nature, the diagnosis must, it appears to me, be comparatively easy and certain. Viewing the whole origin and course of the case, I cannot conceive it possible that the tumour should have been of any other nature, benign or malignant, cancerous, tuberculous, lipomatous, a mediastinal abscess, &c., &c.

2. If I must thus answer the first question absolutely in the affirmative, the importance of the matter depends, I presume, essentially on the second, whether, that is to say, the improvement is real and lasting, whether the cure is complete or only apparent. It is said by authors (conf. Lebert in Virchow's "Pathologie," and Brandes) that aneurisms of the aorta sometimes recede considerably to again occupy their former position, and it might therefore perhaps be feared that in the case described by me, the disease would in a short time again manifest itself. But, so far as I can perceive, the writers do not by the retrocession in question understand a total cessation of all phenomena, both objective and subjective, but only a temporary abatement of some symptoms. When, as in my case, all the physical signs of aneurism completely disappear, when, at the same time, the characteristic subjective sensations cease, and a condition supervenes which must be looked upon as perfectly normal, and when, moreover, this normal condition is constant during many months, in which the patient improves in general health, I believe we cannot with any reason suppose this improvement to be only temporary and deceptive. It is true that her headache continues, though in a slight degree and with long intervals; but from this alone to infer the latent continuance of the aneurism is to beg too much.*

3. The third question I must also answer in the affirmative, partly because, according to writers on the subject, the acetate of lead is almost the only specific remedy which has any credit; partly because I have always found it capable, at all events for a time, of moderating the symptoms of the disease; partly, finally, because it was, I may say, the only medicine I employed for the cure of the aneurism. Moreover, experience showed me that it was by no means so harmless as Laennec and others have found it to be. The symptoms of poisoning were not only distinct, but highly dangerous to the patient, so that on this account its use had repeatedly to be given up. Such large doses (as much as fourteen grains twice a day for a long time) as Laennec employed I never attained to.

In other points I will let the history of the case speak for itself, and shall abstain from many remarks. I shall add only, that I have not had the opportunity of seeing other cases of aneurism of the aorta, and that possible errors in judgment may perhaps for this reason be excused.

It probably deserves to be remarked that, as will be seen, my case lasted more than four and a half years, while of the thirty which Lebert has collated in reference to this point, only three attained to a duration of four years; but they all, so far as can be seen, terminated fatally.

A DANIEL COME TO JUDGMENT! YEA, A DANIEL!

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—From the tenor of Dr. Drysdale's paper on Emigration published in your journal of the 9th inst., I conclude that he does not mean to vouchsafe any other reply to the questions which I put in my last communication. The learned doctor appears to be at least an adept in the *naso suspendere adunco* line of argument; if gentlemen presume to differ from him and the false prophets who are the objects of his fanatical veneration, they are no thinkers, they are too idle to read the works of these great men, or they are the slaves of vulgar religious prejudices, and their *superficial criticisms* are quite unworthy of the notice of the sublime intellects whose brilliancy illumines and gives piquancy to the *delicate* discussions of the Dialectical Society.

There is no use prolonging this discussion with gentlemen who will only advance assertion instead of argument; but before taking final leave of the subject, there are some points in the doctor's paper which I feel bound to notice.

First, be it known to him that his great prophets, from Malthus to Senior, are all men who have written and taught a system of Political Economy with the view of bolstering up the system of Land and Capital Monopoly; that this primary object has warped all their views with regard to population; and not having the courage to face the difficulties of dealing with the questions of Land and Capital, they endeavour frantically to trample down the masses that seethe upwards continually in defiance of all their repressive schemes.

Again, we take it as conceded that the Malthusians of to-day disregard *in toto* the appeal to the authority of revelation if they even admit an overruling Providence. Knowing this, we only contend with them on the ground of reason and philosophical truth. On this ground we have a right to complain of Dr. Drysdale's sneer at Doubleday's *so-called law of nature as miraculous.* Doubleday never pretended to advance it as other than a simple law, by which the increase or decrease of any species was connected with the supply of food. The results of the causes unfolded by Doubleday's line of reasoning had previously presented themselves as conclusive to all unprejudiced thinkers; but to him the merit belongs of having discovered and unfolded the recondite principles which govern the laws of the increase and decrease of populations.

Dr. Drysdale's groundless assertion that the aristocracy have usually large families is sufficiently answered by the fact that every year three or four peerages become extinct.

In conclusion, I repeat that no answer has been given to the question—How are early marriages to be rendered unfruitful? The debate of the Dialectical Society and the frequent allusion to the skill of the French peasants point to the suspicion that the practice hinted at is so vile that it cannot be stated openly or in print, but is intended to be whispered into practice. That the Malthusians will fail in their disgusting enterprise I have not the slightest doubt; and that the masses of the people will repel their advances with the same scorn with which the medical profession received them when laid before us so offensively by Lord Amberley. At the last election, the Westminster men showed their appreciation of such views by relegating to his study *the greatest thinker of the age.* Honour to them for their public spirit.

Yours, &c.,
Ewing Whittle, M.D., M.R.I.A.,
Lecturer on Medical Jurisprudence to the Liverpool Royal Infirmary School of Medicine.

Liverpool, June 12, 1869.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I paid a visit to the Royal Infirmary to examine the results of the carbolic treatment under Dr. Lister's own management. My visit was short, but Dr. Lister took much trouble in pointing out the mode of treatment, and the many points to be attended to, to ensure perfect results. As I expect he will before long give us a more compact history of his views and practice than we yet have, I will not enter here on the particulars, suffice it to say that any one who enjoyed the favour of an hour's conversation, and, I may say, instruction from him, as I fortunately have had, will be convinced that, when properly carried out, the carbolic plan of treatment is a great triumph of surgery, and in no point more so than in the application of carbolised catgut sutures; that any mishap arising from their use must have been the result of some unforeseen point of mismanagement; for it requires, as in every new mode of treatment, that the mind should be ever active, to observe when imperfection in the mode of treatment may arise, and to discover how to avoid it. Indeed, I feel more thankful to Mr. Lister for the course of thought thus aroused in my mind, than for the actual information given. Two cases of a most important nature showed decisively how carbolised sutures of animal organised material may remain with impunity in a wound, and give rise to no disturbance, being themselves gradually removed by the processes of reaction.

---

* Should, however, contrary to my expectation, the aneurismatic symptoms in my patient again appear, I will consider it my duty to give a short notice of the fact in the Magazine.

Mr. Lister is a man in earnest at his work, and though it may take time and labour to induce the profession to adopt his views, he will ultimately have his reward.

Glasgow. TRAVELLER.

MR. STAPLETON'S METHOD FOR TREATING FRACTURES OF THE FEMUR NOT NOVEL—VIZ., BY WEIGHT AND PULLEY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Under the above heading, in your last impression, I find Dr. David Jacob, of Maryborough, writes :—"Thirteen years ago *I devised this method*, and have continued to make use of it, and modifications of it, in the practice of the Queen's County Infirmary," &c. On reference to my notebooks, when resident pupil in the Meath Hospital *twenty-three* years ago, I find I was entrusted with the care and management of a case of fracture of the femur, treated on this principle, by the late Sir Philip Crampton, my respected master, one of the surgeons of that institution. On several occasions since then, and particularly in one recently, with marked good results, I have adopted *his* principle in my own practice. That Sir Philip was the *originator* of this method on this side of the Atlantic I feel fully convinced, and I wish to record the fact ; but Sir Philip Crampton, it appears, only followed in the wake of M. Daniell, of Georgia, U.S., who recommended the weight and pulley in the year 1829 (vide *American Journal of Medical Science*, vol. iv., p. 330 : 1829) ; and that Dr. Dugas, of Georgia, devised this method with the modification of four splints, alluded to by Dr. Jacob, fifteen years ago, consequently two years antecedent to the adoption of them by Dr. Jacob (vide *Southern Medical Journal*, February, 1854).

Faithfully yours,

HENRY J. SMITH.

Donaghmore, Borris-in-Ossory :
June 12, 1869.

PORTO MAURIZIO AS A HEALTH STATION ON THE RIVIERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The rapid rise and annually increasing number of visitors who winter in the sanitaria of recent creation on the Riviera—Menton and San Remo—prove that the climatic advantages and the *agrémens* possessed by them, as also by the adjacent stations on this part of the Mediterranean coast, are becoming more and more appreciated, so that in full seasons there is sometimes a difficulty in finding suitable accommodation.

While passing a few days at San Remo last winter, my attention was directed to the neighbouring town, Porto Maurizio, as a locality very favourable for the formation of an additional health resort on the coast, by Dr. Panizzi, of San Remo, who, from long knowledge of it, entertains a high opinion of its capabilities to meet the requirements of many seekers of health by the agency of a mild climate. I consequently visited Porto Maurizio in company with Dr. Panizzi, and, from what I saw of the place, was led to share his conviction, and am, therefore, induced to make known its leading characteristics.

Porto Maurizio occupies an elevated position, overlooking the seashore, and stands out as a prominent object in the view from the east and west. It is a two hours' drive from San Remo by the cornice, the road not passing through it, but winding round its base to the adjacent town Oneglia (half-way between Nice and Genoa). It is the chief and most commercial town of the Riviera, as far as Lavona, being the seat of a Prefecture, and numbering upwards of 7,000 inhabitants, including many well-to-do private families. The necessaries of life (fish, meat, poultry, vegetables, water, &c.), are abundant, and of good quality, and living is reasonable. The streets of the modern portion are wide, clean, and flag-paved, containing good houses and shops ; the principal one, Carlo Alberto, extends through the town in a direction from east to west, from it diverge the Maria Christina, and smaller streets, ascending to the old town, the streets of which are for the most part narrow (several of the houses being joined to the opposite ones by buttresses), and not carriageable, though containing a few fine palaces. This upper portion, however, comprises a spacious Place, one side of which is occupied by a handsome church, with marble façade, and rich interior decoration, which, in an architectural point of view, would do credit to any capital. On the opposite side is likewise a handsome edifice, the municipal palace, containing besides smaller apartments for the transaction of official business, a large saloon for the meetings of the municipality, which is occasionally used for exhibitions, concerts, lectures, &c. In this part of the town is also the large convent Chiara, from the elevated colonnade of which a fine view is obtained of the coast and country westward.

The newly erected theatre, also with marble façade, in the strada Carlo Alberto is near its completion. There are besides a *cercle* frequented by the principal inhabitants, and two or three hotels, the principal one, Hôtel de France, being situate at the eastern extremity of the street.

The port is spacious, and capable of admitting vessels of moderate draught. The coasting trade is tolerably extensive, steamers ply two or three times a week between this port, Genoa, and Nice ; the express day boat from Nice touches here, and makes the passage in about four hours, to Genoa in five or six hours.

The surrounding country is pleasing and well wooded, a small extent of verdant plain stretches to the encircling olive-covered hills of moderate height, the acclivities of which are dotted with villages and detached houses, and above which rises a higher range, affording protection to the lower grounds from the north winds, to which the upper part of the town, from its elevation, is, in some degree, exposed, as also to the wind from the west *(ponente)*. That the general temperature is lower than at the other health resorts on this coast, is proved by the circumstances that oranges and lemons are not cultivated at Porto Maurizio. In the lower portion, however, and especially at a little distance under the hills, there are sheltered sites well protected from wind. One of the best on the western side is beneath the hill station, Maria del Monte, on which stands the chapel of the Madonna, and whose summit is crowned by a ruined tower, whence may be enjoyed an extensive land and sea view ; other available sites in this part are beneath the hill on the acclivity of which stands the village Pegli, and among the olive plantations near the sea, a little raised above the shores.

On the western side, a few minutes' walk from the town, is the district of St. Lazarus, enclosed by hills on all sides but the south, and possessing a mild and equable temperature ; a little farther off northwards (about twenty minutes distant), is the village of Arbato, on the acclivity of a hill, to which leads a good road, where, on account of the superior warmth of the climate, natives affected with pulmonary disease are sent.

There is already a certain amount of accommodation at Porto Maurizio, which will speedily be increased by the erection of houses and hotels in favourable positions. A few commodious villas are let to strangers—one of the best in the lower part of the town, the villa Ricci, has the advantage of a large garden ; the villas Littardi and Rambaldi are also suited to the reception of families, the latter is a handsome edifice, with grounds at some distance west of the town overlooking the high road. Oneglia, a town of considerable size, and presenting an animated appearance, is about a twenty minutes' drive from Porto Maurizio. The climate partakes of the general characteristics of that of the Riviera—clear blue skies, sunshine, little rain in winter, snow being rarely seen, except occasionally on the higher hills. The upper part of the town, as already mentioned, is too exposed to winds to be available as a residence for delicate invalids after the winter has set in, the mistral (north-west), which is so inconvenient on the western shore, is but little felt at either San Remo or Porto Maurizio, on account of their position so far to the east. There do not appear to be as yet meteorological data whereon to form a closer estimate of what, in a climatic point of view, may serve to distinguish Porto Maurizio from the existing health-stations of this coast.

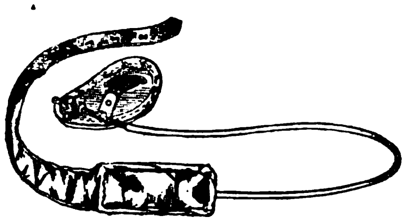
EDWIN LEE, M.D., M.R.C.S.

London : June, 1869.

Inventions.

A NEW TRUSS.

Mr. Miller, of 29, Leicester square, has sent us for inspection a new truss, of which the following is a diagram.



In the ordinary trusses there are two pressures, fore and aft. The fore pressure starts from the hips to the pubis, hence a great deal of the strength is lost at the point where it is most needed. By carrying the band round the opposite side to the rupture, and having the spring in the head of the truss, a great advantage is obtained. The spring effects the closure of the external ring, and by fastening the straps the pad is held firmly along the whole length of the inguinal canal. It is also equally serviceable for inguinal and scrotal hernia.

Prior to the introduction of this truss, there was only one kind suitable for scrotal hernia, and that was an ordinary truss with a perineal strap; but this will entirely supersede that kind of truss, as it does not require an under or perineal strap, which is at all times most objectionable.

◆

A deputation, consisting of the President ot the Royal College of Surgeons, Ireland, Dr. James S. Hughes, Secretary of the Council of the College, and Dr. Edward J. Quinan, Secretary of the Irish Medical Association, waited this day (Monday) by appointment, upon the Chief Secretary for Ireland at his office in London. The deputation was accompanied by Mr. Jonathan Pim, Mr. Lynam, Mr. Peebles, Dr. Brady, and several Irish members, who entered warmly into the discussion of the claims of the Irish Poor-law and dispensary medical officers, to have superannuation extended to them, and appeared to make a good impression upon the Chief Secretary. Dr. Brady's Bill is down for a second reading this day (Wednesday), and if the Irish members who have promised their support will but attend, there is every probability that it will pass this Session.

◆

Medical News.

Royal College of Surgeons of England.—The following Members, having passed the required examination for the Fellowship on May 31st and June 1st, were, at a meeting of the Council held on the 10th inst., duly admitted Fellows of the College :—

Aveling, Chas. T., M.B. Lond., Homerton; diploma of membership dated May, 1865.
Beck, Marcus, M.B. Lond., Isleworth, Middlesex; July, 1865.
Bradley, Samuel M., Manchester; June, 1862.
Bush, John D., Hanover square; May, 1866.
Coates, Matthew, Wellington road, St. John's Wood; January, 1859.
Fuller, Charles C., Albany street; February, 1856.
Jones, George T., Watford, Herts; July, 1849.
Michell, Thomas, M.B. Lond., Redruth, Cornwall; December, 1859.
Robson, Frederick A.H., M.D., Great Marlborough street; June, 1856.
Savage, Thomas, M.D., Bordsley, near Birmingham; November, 1860.
Sims, Francis M. B., L.R.C.P., Down street, Piccadilly; November, 1865.
Tay, Waren, Finsbury square; April, 1866.
Walker, George E., Downshire hill: April, 1863.
Winkfield, Alfred, Radcliffe Infirmary, Oxford; December, 1859.
Woodcock, John R., Holcome, Manchester; July, 1864.
Wright, Robert T., M.D., Royal Victoria Hospital, Netley; April, 1866.

It is stated that all the candidates admitted to examination were successful.

Among the objects that may be seen in the Brighton Sanitary Museum is one which must be regarded with general interest. We refer to a model of an "Elastic Belt for Infants." It is contributed by a lady well known in connexion with measures of sanitary reform, who invented the belt, to supersede the use of the objectionable "roller" and "stays" so injurious to the delicate frame of the infant. The "belt" is manufactured by Messrs. Thomas, of Brighton.

Accident to Professor Bunsen, of Heidelberg.—This eminent chemical philosopher has lately been severely wounded in the face and hands by a laboratory explosion. It will be remembered that Professor Bunsen almost lost an eye some time ago by a similar explosion, but completely recovered. It is to be hoped that the present accident will have as favourable an issue as the former.

Odontological Society of Great Britain.—At the ordinary monthly meeting of this Society, held on Monday, June 7th, 1869, J. H. Barrett, Esq., in the chair, Mr. Alfred Coleman read a paper "On the Treatment of Periodentitis by Replantation," and Mr. Snape, of Chester, read a paper "On Electricity as a local Anæsthetic."

University of Cambridge.— T. Calliphronas, of Caius College, has been elected to a scholarship for Chemistry; and W Simpson son of Sir James Simpson of the same college elected to a scholarship for Anatomy and Physiology. Hicks, Lee, and Adams have all obtained prizes for Natural science in Sidney College. These gentlemen are already Natural Science scholars of the College.

Information relating to non-collegiate students in the University of Cambridge issued June, 1869, by the board appointed to superintend and admit them. Students may be admitted members of the University without being members of any college or hostel. Such students will keep terms by residing in Cambridge with their parents or in lodgings duly licensed, and will be entitled to be matriculated, examined, and admitted to degrees in the same manner and with the same status and privileges as Students who are members of colleges. They will be under the jurisdiction of the vice-chancellor and proctors, and will be required to pay due obedience to all academical regulations. They will be under the supervision of the Censor, to whom they may apply for advice and direction, and by whom their daily residence in the University will be registered. They are to report themselves to him on their arrival in Cambridge, and at the end of each term's residence to obtain leave from him to go down. During residence they are to call on him, and write their names in a book to be kept for the purpose, at times to be indicated by him. Each is to make a written report, when required by the Censor, for the information of the Board, as to the place of religious worship he attends, and as to the studies he is pursuing and the lectures he is attending or the instruction he is receiving. The fees payable will be the following :—

	£	s.	d.
To the Board, per annum	5	5	0
Capitation Tax, per annum	0	17	0
Matriculation Fee	0	15	0
Previous Examination Fee	2	10	0
For B.A. Degree	7	0	0
For M.B. Degree	8	0	0

Non-Collegiate Students will be admitted to the University library and museums and to the professors' lectures under the same regulations as the other students, and it is already known that several college lectures will be open to them. Further information on this subject will be issued as soon as possible after the commencement of the Michaelmas term. They will be able to compete for University scholarships in the same manner as other students. All applications for admission and other communications are to be addressed to the Censor, the Rev. R. B. Somerset, Trumpington road, Cambridge.

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

Correspondents not answered should look to the answers the following week.

Dr. Burn.—Please send Part II. at your convenience.

Dr. Davidson, Chester, will please receive our best thanks.

Dr. Hayes.—The proof was duly sent to you for correction.

Dr. G. Robertson.—On Diseases of the Heart, see previous reply.

Dr. Hadden.—The paper was duly received, and is in the printer's hands.

M. A. B.—We have not seen the Report to which you direct attention. The paragraph is inserted elsewhere.

The Medical Press & Circular.

LUPOID ULCER OF THE LEG, WITH EXTENSIVE WARTY GROWTH.—OPERATION.

By Benjamin F. M'Dowell, M.B., T.C.D.,

Surgeon and Lecturer on Clinical Surgery to Mercer's Hospital; Surgeon to the Lock Hospital, &c.

It is seldom that the surgeon is called upon to adopt so grave a proceeding as the amputation of a limb for an ulcer; but the history of the following case argues that such may be not only justifiable but even necessary to save or prolong the life of an individual.

James Keely, a man over six feet in height, and of powerful frame, but over seventy years of age, was admitted under my care to Mercer's Hospital, from the county Longford, on the 24th August last year, suffering from a large ulcer, with extensive warty growth on the anterior and external surface of the inferior third of the right leg.

He appeared much emaciated, and complained of constant eating pain in the ulcer, chiefly along its margin, which deprived him of his sleep.

He stated that about thirty-five years previously he got a kick from a horse on the site of the sore, which bled profusely at the time, but neither of the bones of his leg were broken. Under treatment he got soon well, but from his description it would appear that the integument was ever after adherent at the seat of the injury, and he was obliged to wear constantly a bandage to prevent his foot and ankle-joint from swelling and becoming painful. Occasionally a sore would form, which yielded from time to time to proper treatment. In December, 1867, the present ulcer first appeared, and was soon after accompanied by a peculiar warty and highly vascular growth, which is faithfully pourtrayed in the annexed lithograph by Mr. Burnside.

Several remedies were tried in vain, and at length he determined to seek admission to Mercer's Hospital, as he was rapidly losing his health, from the irritation of the ulcer on his system, the profuse discharge, and the frequent hæmorrhages by which it was accompanied.

A laboured description of the sore is not called for, on account of the excellent lithograph by which it is illustrated; but I may remark that its edge was considerably everted, irregular in outline, and the surrounding integument dense, livid, and painful. I thought it due to conservative surgery to adopt a judiciously-applied escharotic treatment before resorting to operation. Accordingly, I coated the ulcer with chromic acid (which has been lately so much lauded for its efficiency in such cases), on three different occasions, but without influencing in any way its condition. I also used the chloride of zinc, a caustic in which I have great confidence, but with the same discouraging result. I now had to leave town for some time, and my colleague, Mr. Morgan, kindly took charge of the case. He injected strong solutions of tannin into the more prominent parts, but without permanent benefit. On my return, it was evident no step remained but amputation of the limb to save the life of the patient, as he was still more emaciated than when I left; and upon consultation this proceeding was determined upon. Accordingly on the 14th of October I performed the operation by the double-flap method about a hand's breadth below the knee. The patient was prepared by a gentle aperient the night before, and a brandy-and-egg mixture two hours before he was chloroformed.

It is needless to give the steps of the operation, or the after-treatment: suffice it to say, the patient progressed most favourably, and six weeks after was able to leave the hospital, with a good stump and much improved in health; but a severe sore throat detained him in hospital until the 1st March, when he was discharged quite well. I have since heard from him: there has been no ulceration, he has a useful stump, and he is in excellent health and spirits.

I thought this case worthy of an illustration. It is like the warty ulcer of Marjolin. I have applied the term "cancroid," or "lupoid" to it because I believe from its obstinacy to treatment, its irregularity of outline, its painfulness, its everted edges, and the hæmorrhage by which it was attended, that it may fairly be classed in the category of malignant diseases.

◆

THE LEGALISED ADULTERATION OF SNUFF.

By Chas. A. Cameron, Ph.D., M.D., L.K. & Q.C.P.I.;

Professor of Hygiene, Royal College of Surgeons; Lecturer on Chemistry in Steeven's Hospital and the Ledwich Schools of Medicine; Analyst to the City of Dublin, &c.

At one time, not very remote either, the introduction of powdered tobacco into the human nose was a fashionable habit. In our days the practice is on the decline amongst the upper and middle classes of society, but it prevails rather extensively amongst the lower sections of the community. Snuff is manufactured largely in Ireland, and there are varieties of that article peculiar to this country. The revenue derived from the tax imposed upon snuff is very considerable, and the manufacture of this costly article is under the *surveillance* of the officers of the Board of Inland Revenue. The revenue from snuff is very considerable; the Excise officers keep a close watch upon the movements of the manufacturers of this article, and suspected samples are frequently seized, and forwarded for examination to the Excise Laboratory at Somerset House, London. Notwithstanding these precautions, there is hardly any article in common use more extensively adulterated than snuff. In this communication I do not propose dealing generally with the subject of snuff adulteration, but shall merely make a few observations in reference to a particular species of sophistication for which I think the Excise authorities are more to blame than even the manufacturers.

In the year 1842 an Act of Parliament was passed, prohibiting, under severe penalties, manufacturers of snuff from mixing with that article any substance other than the following :—"water, or water and salt, or alkaline salts only, or lime water in snuff known as Welsh or Irish snuff." Any one convicted under the provisions of this Act was liable to a fine of £300. In addition to the substances above named, the manufacturers were permitted to add essential oils to their snuff for the purpose of imparting an odour to it.

The Irish and Welsh manufacturers of snuff, being allowed to use lime, gradually increased the quantity until in some cases as much as 20 per cent. was employed. This was clearly a violation of the spirit and even of the letter of the law, which permitted the use of lime water, but did not specify lime itself. Snuff, however copiously damped with lime water, could not retain much of the earth, owing to its sparing solubility in water; the lime, therefore, must have been added in the form of powder. The Excise authorities in August, 1867, procured an Act of Parliament (30 and 31 Victoria, cap. 90) which limited the quantity of lime used in the manufacture of snuff to 1 per cent. In the nineteenth section of the Act, the following words refer to Irish and Welsh snuff:—"Be it enacted, that if any person, being a manufacturer of, dealer in, or retailer of tobacco or snuff, shall have in his custody or possession any snuff in which, on examination thereof, there shall be found to be any quantity of the oxides of calcium and magnesium, or of either of such oxides, exceeding by 1 per centum the proportion of the quantity of such oxides contained in the tobacco, or tobacco stalks, or returns of tobacco from which such snuff shall have been manufactured, or shall be in course of manufacture, or if any such person shall have in his custody or possession any snuff in which, on examination thereof, there shall be found any quantity of the said oxides, or of either of them, exceeding the proportion of thirteen pounds weight of such oxides in every hundred pounds weight of such snuff, he shall forfeit £200 and also the said snuff: provided that any sample of snuff, tobacco, or tobacco stalks, or returns of tobacco, which shall be examined for the purpose of ascertaining the quantity of the said oxides contained therein, shall first be dried at a temperature of 212 degrees as denoted by Fahrenheit's thermometer; and for the purposes of this section the term 'snuff' shall include all snuff and all tobacco, tobacco stalks, and returns of tobacco which shall be in course of manufacture into snuff."

It is much to be regretted that the Excise authorities, when dealing with the subject of the excessive additions of lime to snuff, did not take into account the fact that large quantities of alkaline salts might be, and indeed were, used in the preparation of snuff. A small quantity of certain alkaline salts is supposed to be necessary in order to increase the pungency of snuff; but, in permitting the use of these salts, the Legislature never intended that they should be employed in large proportions. As the law stands at present, a snuff manufacturer may be fined £300 for adulterating his snuff with 1 per cent. of ochre or sawdust, but he may legally vend an article composed of equal proportions of powdered tobacco and carbonate of potash! It may be said that no manufacturer would use excessive quantities of alkaline salts, for the quality of his snuff would be seriously injured by such a practice. There are, no doubt, many manufacturers who employ alkaline salts only for a legitimate purpose—namely, to increase the pungency of the odour of their snuff; but I have satisfied myself that in the larger proportion of Irish snuff the amount of alkaline salts is excessive, and is employed for the sole purpose of cheaply increasing the weight of the snuff.

The amount of mineral matter (ash) in tobacco is considerable; the proportion found in a large number of specimens of the dried leaves of Havana tobacco, analysed by Casaseca, varied from 16 to 23 per cent.; in Turkish tobacco, Vogel found from 17 to 23 per cent.; in Russian, 21·9 to 24·9 per cent.; and in Grecian, 19 per cent. of ash.

In twenty-eight specimens of snuff which I obtained from different shops in Dublin, I found the following proportions of mineral matter :—

This snuff had evidently been adulterated with bicarbonate of soda, probably to the extent of 30 per cent. Many of the other samples contained excessive quantities of lime, sal-ammoniac, soda salts, and potash salts.

It is not necessary to occupy space in giving full details of the analyses of Irish snuff which I have made; it will be sufficient for my present purpose to mention that in the majority of the samples which I examined I found enormous proportions of the carbonates of soda, carbonate of potash, and sal-ammoniac. In two or three cases I found lime in excess of the amount tolerated by the Legislature, and in one case chloride of lime was present.

I find that many of the Irish manufacturers of snuff sell it wholesale at 3s. per pound; whilst tobacco stalks, the cheapest part of the tobacco plant, cannot be purchased at less than 3s. 3d. per pound. As considerable diminution of weight occurs in converting tobacco into snuff, and as the leaves as well as the stalks of the plant should be ground, it is evident that good snuff, containing only normal amounts of mineral matter, could not be sold without loss at less than 4s. 6d. per pound. Those manufacturers, therefore, who offer snuff at 3s. per pound must vend an article one-third of which must be added saline matter. If the quantity of lime be above that allowed by the Act of Parliament to which I have above referred, the manufacturer is liable to a heavy fine, but he may legally vend an article containing 90 per cent. of alkaline salts! I am satisfied that every respectable manufacturer would be benefited by a total prohibition of the practice of introducing alkaline salts into snuff. So long as the law permits the addition of comparatively cheap substances to so costly a commodity as snuff is, so long will there exist an unhealthy competition in this trade—a competition, too, which is injurious not only to the public, but to the conscientious manufacturers of snuff. It is quite evident that the manufacturers who fabricate a pure snuff, or one containing only 3 or 4 per cent. of alkaline salts, cannot compete on equal terms with those who mix from 10 to 30 per cent. of earthy and saline matter with their snuff. The obvious remedy for this state of things is to utterly prohibit the admixture of any kind of earthy or saline matter with snuff. There are snuffs possessed of the most admired odour which contain only tobacco and essential oils. In Ireland the manufacture of snuff is in most cases far too expeditiously performed. In some manufactories the tobacco stalks are converted into snuff in less than two days. Of course such hastily-made snuff requires lime, sal-ammoniac, or the alkaline carbonates in order to develop from it a pungent odour.

In France this industry is conducted in a highly scientific manner. The tobacco is subjected to repeated fermentations, and put through elaborate processes, the duration of which is sometimes nearly two years. Snuff made in this way possesses naturally a pungent odour, but one very different from that developed in hastily-prepared snuff by the action of alkaline matter.

I have noticed that in the very light-coloured snuffs on sale in Dublin, there is always a considerable amount of saline and earthy matter. Some specimens of highly-coloured and of light brown snuff which I examined were free from this form of adulteration.

With respect to the physiological action of snuff containing from 20 to 50 per cent. of alkaline substances, nothing is, of course, known, because the question does not appear to have been previously raised. I cannot, however, avoid thinking that snuff of this kind must produce a direct and injurious effect upon the Schneiderian membrane.

◆

PAINFUL SUBCUTANEOUS TUMOUR.

By R. L. Swan, F.R.C.S.I.,

Resident Surgeon, Dr. Steevens' Hospital.

The pain which is so characteristic of those tumours is suggestive of interesting questions as to its cause and true seat. It would appear, from the investigations of Paget, Bennett, and other writers, that the intimate structure of those tumours is not often consistently alike; that the presence of a distinct nerve-fibre leading to the tumour is seldom ascertained; and that the integument is usually adherent to them. These statements would seem to show that it is no inherent peculiarity in the tumour itself which gives it its distressing character of pain, but an alteration in the sensibility of the skin covering it. The following case, in which the tumour consisted of a cyst containing an intra-cystic growth, will, I think, in its details, bear on the question:—

J. S., æt. fifty, a gentleman of healthy appearance and active habits, came from the country for treatment some months ago. Two years before he noticed a tender spot on the outer side of his right thigh, about the centre. The uneasiness was then of a trifling character, accompanied by an itching in the vicinity, which caused him great irritation, especially at night. After a time he became sensible of a hardness under the integument, and afterwards a small tumour made its appearance. The pain has lately increased to such an extent as to amount at times to positive agony. He describes it as intermittent in its nature; sometimes occurring spontaneously, or, as he states, from his attention being directed to the part; at other times excited by an accidental touch or blow; and always aggravated at night.

On examination, a purplish tumour, the size of a large pea, was observed. The integuments surrounding it were red, and the temperature elevated.

On manipulation, which caused him considerable pain, an indurated mass, an inch in diameter, was discovered closely adherent to the integuments, but movable on the fascia of the thigh. The small purplish tumour evidently contained fluid, and could be emptied by pressure. The patient was extremely anxious for its removal, as he was deprived not alone of sleep, but also of exercise, especially on horseback, to which he had been accustomed.

On consultation with Mr. Colles, it was determined to remove the tumour with the knife. This was accordingly done by an oval incision, cutting clear of the subcutaneous indurated mass. The edges of the wound were brought together by a few sutures of silver wire, and it soon became healed. I had an opportunity, some weeks having elapsed since the operation, of seeing the patient. At first some tenderness of the surrounding integuments remained, but he has lately been free from pain.

On examining the tumour, it was found to consist of a firm greyish capsule, adherent to the skin and imbedded in the subcutaneous fat. On opening the capsule, a small quantity of blood-like fluid escaped, which surrounded a dark-coloured mass growing from the inner side of the capsule by a peduncle. The small purple tumour seemed to be a protrusion of this intra-cystic growth through the cyst wall.

The growth within the cyst was composed of a fibrous trabecular structure, containing a small quantity of fluid in its meshes. By the most careful examination no nerve could be discovered having any connection with the tumour, which was enveloped, except where attached to the integument, by apparently healthy fat.

◆

HYDROCEPHALUS ACUTUS.

By J. Waring Curran, L.K. & Q.C.P.I., L.R.C.S.I., &c.,

Bacup, Manchester.

Infantile disease is ever one of interest, and not unfrequently of the greatest uncertainty and difficulty. Few there are whose interest cannot be stirred, whose compassion and sympathy cannot be elicited, as day after day he stands by the cot of ailing innocence, observes that constant attendance and devoted care, so closely allied to holiness itself, of the anxious watchful mother, whose tender and undying solicitude is wrapped up by so many binding ties in the welfare of her child, whilst her countenance, indicative of that painful enduring uncertainty which woman alone in their mental distress know how to bear, turns with its undescribed and indescribable, piercing, scrutinising stare for all that can be told her respecting her child's malady, whether the progress of the disease may be arrested and death warded off, or that temporary relief alone can be afforded. In no disease more frequently than hydrocephalus will this be experienced, and in no disease does the practitioner find himself in greater difficulty at arriving at an accurate prognosis. When so distinguished an authority as Dr. West places on record the fact that every example of hydrocephalus is fatal, and when the eminent Gölis, on the contrary, affirms that cases commencing after birth, when early seen, he has been enabled to save the majority of them, well may the practitioner who has not thoroughly studied the subject be at a loss to decide the probable result without seriously compromising the accuracy of his prognosis.

My object in this paper is to record the treatment I have found, after a number of years, to be most efficacious, whilst I avoid the many reputed remedies alleged to have proven so successful in the practice of others, whilst I dispute the accuracy of Dr. West's decision respecting the mortality, and coincide in the opinion advanced and advocated by the valued author of "The Water Stroke." I believe, and experience has established the opinion, that if hydrocephalus be seen in its first stage, when there is *exalted sensibility, with quick pulse,* irritability, general feverishness, offensive breath, morbid susceptibility to noise, muscular depression, photophobia, constant vomiting, difficult to control at first, greenish fœtid evacuations, perhaps constipation, screaming—the *cri hydrencephalique* of M. Coindet—when awaking from sleep, with grinding of the teeth, and a peculiar rolling movement of the eyeball, with perhaps strabismus or amaurosis, that the disease is remediable, and will yield to treatment. When we meet with a case with "*diminished sensibility and slow pulse,*" becoming rapid, as we are practicably told, when the little patient is raised, when the countenance is pallid and stupid, and the patient listless, the stretched-out arms trembling and catching, the pupils dilated or contracted with unequal action of the iris under the influence of light; then I consider the efforts of our art fruitless, and of as little avail as when treatment is attempted in the stage of coma, with quick pulse, excessive weakness, and paralysis or convulsions, the antecedents of impending dissolution. If my memory serves me correctly, to Dr. Henry Kennedy is due the credit of first calling attention to the important practical fact that the similitude of the symptoms to those of commencing typhus was observed by him; and I must endorse this observation by remarking that, in an older class of hydrocephalic patients, this remark is strikingly appreciable. I have also noted the fact that female children are more frequently affected than males, and in either sex the first born are the most liable; indeed, I have never seen a child under treatment whose mother had previously borne four children, and I account for it in this way: that as congenital hydrocephalus is most frequently dependent on some tubercular diathesis descended from the parent, that it not unfrequently happens the one affected, and that chiefly the mother, dies before a large family is borne. This is a rule which, if carefully observed, there will be found few exceptions to. Of course I write of hydrocephalus having a congenital origin, and not those varieties dependent upon dentition, inattention to the state of the digestive organs, the sudden curing of eczema or other cutaneous affections, measles or scarlatina, producing a deterioration of health and a predisposition to disease, the retrocession of parotiditis, intestinal worms, or perhaps gastritis, but where a history of scrofula or syphilis can be traced to the parents of affected patients, so far as this observation is concerned.

The first step which I invariably take in the treatment is the exhibition of a mercurial, followed in a couple of hours by a mild aperient, if practicable. Not unfrequently the vomiting renders an enema requisite, and a mixture containing the fourth of a drop doses of dilute hydrocyanic acid, one drop of chloric ether, and five grains of the light magnesia in dill water. If there be any suspicion about the mouth, I invariably incise the gums. I am not an advocate for depletion; I believe the application of leeches will increase the tendency to effusion, and that every object they can serve will be more advantageously supplied by purgation.

Once the case is clearly established, I have an oil-silk-cap made, and lined with swan down; this I have run with cases, or sheaths containing tape, so that, by tightening the tapes, it will fit precisely and accurately to the child's head, previously smeared over with mercurial ointment. The mercury is taken up with greater rapidity, and the child's head is in a perpetual vapour bath. I prescribe no mercury by the mouth after this, I rely solely upon diuretics and diaphoretics; and the acetate of potass, tincture of squills, spirits of nitre, and decoction of broom answers every purpose. The moment the most acute symptoms subside I feed, and when I say this I see that the child has some nutriment every hour besides the breast, which, if possible, I dispense with, as I consider a change in diet essential. I arrange that three or four cups be at the side of the fire, in one a little beef-tea carefully prepared, in another cup some egg and milk, in another some Revalenta Arabica food, and direct that the child get a little of each alternately, so that the stomach will not loathe any particular one; but if there be a continuance of gastric disturbance, then I exhibit nutritious enemata. The collection of mucus at the side of the eye is sometimes a disagreeable complication; a carbolic acid collyrium I have found most efficacious. In some instances where the patient made a good recovery, yet the effusion continued persistent, I found the greatest benefit from proportionate doses of Dr. Horace Dobell's pancreatic emulsion, the inunction of cod-liver oil, and the iodide of potassium ointment, with the oil-silk-cap firmly and accurately applied. In cases where the little patient's head fell helplessly backwards, forwards, and laterally, and where he lay on the pillow with a triangular face and precocious appearance, unable to raise the heavy head, I have observed the most salutary and satisfactory results from the continued inunction, wearing the cap with a binder of silk ribbon firmly surrounding the cranial bones, perseverance in diuretics, attention to the bowels, and the occasional administration of a mercurial laxative. Should epileptiform seizures manifest themselves early in the disease, they are, I consider, one of the worst symptoms, and demonstrate extensive mischief; indeed, how often are they one of the first symptoms! The child out of health has been unnoticed, a convulsive seizure first excites alarm, the medical attendant is summoned, and finding that it yields to a warm bath, a mustard application to the nape of neck, incising of the gums, and an aperient, he ascribes it to dentition; but the mischief steadily goes on, and in a few hours the nature of the case is revealed, and all doubt unmasked. On the other hand, should they set in later, although I cannot designate them good, I must not pronounce them untoward symptoms—the brain is recovering itself, and they are the effect of irritability, which readily yield to bromide of potass, tincture of hyoscyamus in camphor julep; but these seizures must not be confounded with the convulsions attending the paralysis, which must terminate in dissolution.

◆

THE REMOVAL OF AN UNUSUAL TUMOUR OF THE SUPERIOR MAXILLA.

By H. R. Hadden, M.D., F.R.C.S.I., Clonakilty.

Mary Kane, the wife of a labourer, aged fifty, was admitted into the Clonakilty Workhouse Hospital, on the 11th February, 1869, for the removal of the left superior maxilla. Three years before a fleshy tumour had begun to grow from the upper gums, and gradually increased in size, without causing any suffering except from its mechanical inconvenience, until it filled the whole cavity of the mouth, projecting between the upper and lower molar teeth on the right side, and being grooved by them. On the left side it had displaced the superior molars, and connected itself with a similar growth, the size of a hen's egg, springing from the outer surface of the alveolar ridge and causing the left cheek to project; the anterior wall of the antrum was bulged prominently forward as high as the infraorbital foramen, while its internal one could be seen forming a rounded protuberance in the left nostril but not passing the median line.

The eye was rendered somewhat prominent, but not otherwise displaced.

The upper surface of the tumour in the mouth was so closely adapted to the vault of the hard palate, that the finger could not be insinuated between, but a bent probe passed carefully from the right, proved that the pedicle from which it grew did not pass the median line; when the left index finger was passed round between the tumour and the cheek at the right side, the growth was found to fill the pharynx, and lie against the bodies of the cervical vertebra by its inferior extremity, where the finger could be passed between its nail resting on the spine and its pulp against the tumour, the velum palate and uvula intervening above.

By its inferior surface, the tumour lay in contact with the epiglottis and tongue, which latter it caused, by its downward pressure, to bulge into the submaxillary regions when the mouth was closed.

The right index finger, when oiled, and passed between the left cheek and the tuber maxillare, above the smaller growth, reached a hard body imbedded in the back of the tumour; which, with great difficulty, could be recognized as the displaced masticating surface of the wisdom tooth; this could also be reached when the left finger was forcibly pressed round from the right side. Just above this point a gum-elastic catheter could be passed round the thick pedicle (six and a half inches in circumference) from which both tumours sprang, a notch about three quarters of an inch deep separating them where the molar teeth had been.

It was thus evident that a considerable portion of the degenerated maxilla was included in this common pedicle. The left hamular process could not be detected, probably due to the backward displacement of the pterygoid plates of the sphenoid and the very little room there was for the finger to move.

No enlarged glands existed. From the examination above described I hoped the disease was limited to the left superior maxilla, and perhaps the palate bone, and determined on removing the inner or both, if necessary.

When she fell asleep for a moment the most distressing breathing ensued, and she awoke in a few minutes suffocating, indeed the mystery to every one was how she breathed or swallowed; yet her general health was good, and her spirits cheerful.

Chloroform was plainly inadmissable, though, were it not from the mouth tumour, I would certainly have administered it from what I have seen of its use in removal of the maxilla in the practice of my old friend and teacher, Dr. H. H. Boxwell, of the County Wexford Infirmary.

Two difficulties existed in the performance of the operation in this case. First, the usual incisions through the soft palate could not be made. Second, when the bone would be isolated it would be impossible to apply the usual downward pressure to dislodge it, and allow of the division of the remaining soft parts behind. To meet those (having first secured my patient in a stout arm chair in the usual way) I passed the chain of an écraseur round the pedicle of the mouth tumour, and also a chain-saw in a gum-elastic catheter, lest it should be required, intending to remove the tumour from the mouth before wrenching the maxilla from its bed.

An assistant now commenced to screw up the écraseur, and the moment the chain tightened on the pedicle I began my incision through the median line of the upper lip, and continued it round the ala of the nose to within half an inch of the inner canthus, then dissected the cheek freely off the tumour, cut through the root of the nasal process of the maxilla into the antrum by one stroke of a powerful bone-forceps, then through its anterior wall just beneath the orbital plate, when I turned the forceps backward and somewhat upward, and severed the bone through its tuberosity.

I now extracted the incisor tooth, pushed the lower blade of the forceps between the tumour and hard palate, the upper one lying on the floor of the nose, and with one stroke divided the hard and soft palates. By this time I hoped that the écraseur would have been through the pedicle, but finding it was not, and under the impression that my patient was suffocating, I seized the bone in a lion forceps, thrust my left index finger behind the tumour, and with one steady pull, the whole mass came away without leaving a shred to be divided. A huge, but healthy cavity remained, the floor of the orbit looking quite normal, and not a trace of diseased tissue to be found anywhere.

The velum pendulum palate was intact. One or two small vessels sprang, but no ligature or cautery was required. All oozing having ceased, and the cavity having been filled with pledgets of lint soaked in perchloride of iron, and having numbered ligatures attached, the lips of the incision were brought together by wire sutures and two hare-lip pins, a single fold of lint over all.

To compensate as far as possible for the absence of chloroform the operation was planned so as to economise to the utmost time and suffering in the execution of it, consistently with the complete removal of the disease; and thus to reduce the danger from shock to the minimum.

For this purpose the knife and écraseur were used simultaneously, the bone-forceps exclusively employed, and the cautery dispensed with; this latter was done with great reluctance, on account of the weight which some eminent surgeons attach to its use, but on the closest examination, both by sight and touch, on the part of my kind assistants, Drs. David Hadden, Garde, Bennett, Heas, and myself, it was concluded that the parts were so perfectly free from disease that its use would be a needless infliction of pain on one who had borne her sufferings with astonishing fortitude.

The removal of the disease occupied five minutes, and so little shock was there, that she walked from the chair to her bed, and with a smile expressed her satisfaction at the removal of "the baby she had nursed for three years" (her own words).

After being settled comfortably in bed, she got some brandy and water, with thirty minims of Battley's sedative; she fell asleep in about an hour.

The operation was performed at noon, on Tuesday, February 16th. At 11 p.m. per pulse was 92; temperature, 101 3-5ths; the flap warm, and but little swollen, the uvula tumid, and lying on the dorsum of the tongue. She was ordered beef tea, and milk and water, reaction having been fully established.

Wednesday, 17th.—Pulse, 88; temperature, 99 1-5ths had a good night; spoke cheerfully and distinctly; no pain; the wound looked well, and the uvula was less swollen.

It would be tedious to follow the case further; not an unpleasant symptom arose, the wound healed completely by the first intention; the pledgets were removed on the third, the needles on the fourth, and the sutures on the fifth day; under the daily use of carbolic acid lotion, the internal parts granulated and healed up kindly; and on the 11th of March, she was discharged, through the guidance and blessing of God in the treatment, as far as I could judge, free from disease.

There are some points of interest about the tumour. Those parts of it which projected into the mouth and underneath the left cheek springing from the inner and outer surfaces of the alveolar process seem to be huge epulitic growths, that occupying the antrum is peculiar in being roofed over where it lay against the floor of the orbit by a delicate shell of bone, which appears to be rather a product of the morbid process than part of the maxilla. The spongy bones being quite healthy, one is led to hope that there may not be a return of the disease.

May 19th.—I have seen this patient to-day (three months after operation), and am thankful to be able to say that there is not the *slightest* evidence of a return of the disease.

◆

A PLEA FOR THE CONTROL OF PROSTITUTION.

By T. C. S.

No. 1.

As it is more than probable that the Contagious Diseases Act, at present only in force at our principal military and naval stations, will be much extended both in character and action, we think it may not be without some interest to republish an article which was originally printed in the *Cork Constitution*, in the year 1855, and in which we laid before the then authorities how such things were managed in continental cities.

Our remarks are based on a review published in the *Medico-Chirurgical Review* of January, 1854, vol. 13, by Dr. T. S. Holland, of Cork, who had great opportunities of investigating the working of this system on the continent; and who, like ourselves, very justly makes no excuse for bringing it before the public: but says, at p. 113, that few subjects (as the one he is about to consider) have such moral and physical relations with the wellbeing of man, or demand more carefully and attentively the attention of the physician and statesman.

The investigation of this subject has much to do not only with the moral, but also with the physical welfare of the present, and is even still more intimately connected with the well-being of future generations. There are no persons who haev the slightest particle of honest feeling about them who will not, the moment they begin to calmly and dispassionately think over the subject, perceive that if there was such a control exercised over prostitution in Great Britain and Ireland as is carried out on the Continent, much good might be done, much crime put down, much good be effected, and an immense amount of misery alleviated. It may be asked, Why in any way countenance such foul proceedings? By bringing crime under public notice, we often induce people to commit crime. But, will those parties permit us to ask them the question, Why is it that the Press is permitted to enter into the most minute detail of how the midnight murderer committed his deed of blood? Are prostitutes more culpable than him? At his trial the deepest sympathies of our nature are called into play; we pity, we commiserate, the man who has shed man's blood; but place a prostitute at the bar of justice for the slightest outrage of the laws, and there is none to pity, none to help her. Until convicted by judge and jury, he is not cast out from the pale of society; but the poor outcast woman is often condemned unheard—it is enough that she is unfortunate. With a kind consideration our rulers have appointed ministers of religion to attend the malefactor, and point out to him that, even in the eleventh hour, a Saviour's arms are open and ready to receive him, a Saviour's lips are uttering, "This night shalt thou be with Me in Paradise."

We speak advisedly when we say that even the minister, in many cases, thinks the poor outcast prostitute too bad to be saved. To withhold the means by which there may be a chance of rescuing these women from a greater fall than they have already fallen to, is not worthy behaviour on the part of those who aspire to guide either the actions or opinions of others.

But let us ask the question, Do we not countenance prostitution? Does not the statesman, as he walks or drives from the Senate House of our great land, see this great and crying evil lying on the main pathway of our streets? Does he not behold it, turn where he may, dressed up in all the painted, blazing, harlotry of wretchedness, seducing with its wiles and snares the children of many a happy home, and leading them headlong to ruin and destruction? The statesman, the philanthropist, aye, the clergy themselves, must acknowledge this; yet with a strange inconsistency of feeling they "pass by on the other side;" with a mawkish sentiment of manner, they shake their grave heads and say, "Oh she is a prostitute, nothing can be done for her; were we to plead her cause, society would scout us from its presence; such characters should not be permitted to live."

If one or other of these men turn to p. 114 of the article we are reviewing, he will see that the Utopian notion of endeavouring to sweep prostitution off the earth was attempted in Denmark.

Referring to laws instituted for that purpose, our author says:—"*These and a long list of other enactments are so stringent in character that they must have interfered with the liberty of the subject, not only suspected of prostitution, but also with the community generally.*" Dr. Holland then asks, "*Is Copenhagen a moral city—does prostitution exist in the kingdom of Denmark?*"

Anyone acquainted with the physical constitution of our race will immediately see the total impossibility of putting a stop to this vice, the greatest that ever a British sun shone on; then the next best thing our statesmen, our philanthropists, should do is, to try and invent a plan whereby the civil liberty of the woman may be preserved, and the public at the same time protected. We stand on the same high principle as the author of the reviews, and say, "*that whatever is likely to conduce to the happiness of man deserves to be heard by man.*"

Berlin.—In this city there is a staff of eighteen men employed in the "Control of Prostitution," of whom four form a kind of council, to receive any points that may be referred to them. Ten are physicians, to each of whom a part of the city is assigned, and there are four surgeons to assist these physicians.

"*This commission has divided prostitutes into two kinds—the tolerated or public—the non-tolerated or secret.*" Our space will not permit us to go regularly through the Regulations, given at p. 115, which the keeper of a brothel has to subscribe to before he or she are permitted to open a house. But we cannot pass them entirely by without drawing the attention of our readers to three or four of the rules, which, if carried out in the United Kingdom, would be of incalculable benefit to society; and we are also inclined to think, even in the present state of the laws, our local authorities could very easily insist on being fulfilled.

For instance, we read at p. 116, No. 7 of the Regulations—"*I promise that the street door shall be kept shut day and night, and if it be at any time found open, I will pay a fine of from* 15s. *to* 30s."

Again at same page, No. 10 of the Regulations—"*I promise that none of the women who are in this house shall appear at the door,*—(we would wish to direct particular attention to the last six words of this rule)—*nor in public gardens, or in places of amusement, nor in dancing rooms or in public walks.*"

We always thought,—and it has become more firmly impressed on our minds since reading these articles of Dr. Holland,—that many and many an unfortunate girl would have been now living in peace and contentment with her family, if such rules as these had been in force in Great Britain and Ireland.

Reader,—be you young or old, you will, I am sure, agree with me when I lay down the proposition that example is contagious, and permit me to ask you, Do not the Legislature of our land, by permitting (as she is called) the gay woman to drive in her carriage, attended by her servant, in mock grandeur and dignity, to our theatres and other places of amusement,—do they not, I say, help to seduce more females than all the honied words the male sex are in the habit of using to carry out their designs? Come with me, fair lady, for one moment into you confined and heated room,—shut in, in some dark lane,—far away from the pleasant green fields—far away from the reviving perfume of earth's luxuriant flowers. Scarce one beam of sunlight can penetrate the small and confined windows. There, on a stool, sits the lonely occupant, her pale and meagre cheek telling too plainly that her earthly career will soon come to an end; but still her pale and attenuated hand, marked with clear blue veins, plies the needle, still that bent body stoops over the allotted task—to stop it were to starve. The work is done at last, and from the employers (often scarcely paid themselves) she receives her miserable pittance, out of which she has to provide clothes, food, candlelight, needles, thread, and lodging-house money. As she passes through the crowded city to her comfortless home, she sees the equipage of one of these women; she sees them dressed in splendid costumes, actually glittering from head to foot in their tawdry finery; men smile on them, and they in return smile on their dupes. Ah! what causes the flush to mantle on your brow, young workwoman? why stand so thoughtful in the midst of that crowded thoroughfare?

Reader, that woman is contrasting her own condition with the gay (?) women she has seen pass her, and, from that fatal hour, it is too sad a picture to pourtray.

The clause "shall not appear at the street door," could it be carried out, would indeed be beneficial to society. For, it is most shamefully disgusting to any well-minded person to be obliged to listen to the foul and blasphemous language which we frequently hear in our streets, as these poor unfortunates ply their miserable trade. Do not such sights tend in a great degree to demoralize our people? and yet we remember when Mr. J. F. Maguire was mayor, he tried during his year of office to rid his fellow-citizens of this nuisance, which all allowed to be a great one; he was told he was going too far, he was outstepping the laws. Well would it have been had he not minded what was said, but acted on his own judgment in the matter, and then we would not be compelled to witness the disgraceful scenes enacted night after night in our most public thoroughfares.

"*The regulation respecting the closing of the street door is so strictly acted upon, that it is at all times necessary to ring before you can gain admittance, and on entering it is immediately closed, as it matters not by whom it is left open or even unlatched; if so the owner is fined, and it is one of the duties of the police to enforce this regulation.*"

The rules No. 16 and 17, viz., "*that no one should enter the house from one o clock midnight until morning*;" "*that the inmates should preserve the greatest possible cleanliness, and if any become sick, that the physician should be immediately notified of the fact*," are regulations of such importance that they require no comment.

We cannot but agree with Dr. Holland, when he says, at p. 118, that any system having for its object the reformation of these women "*should enact that it be a high, a very high, offence to give them credit*;" for, when asked why they do not leave the house, and seek some more honourable mode of employment, their reply is, "*I must first pay my debts.*" The only way, in the author's opinion, to avoid this, would be, to declare the woman non-responsible for any debts she may contract whilst residing in such houses.

It is impossible for us to give our readers the interesting statistics given at p. 125. They most undoubtedly prove that the beneficial effects, the direct humane tendency of a control over and examination of prostitutes, is no longer theoretical or problematical, it has been found to protect women from the ill-treatment they almost invariably suffer from the owners of brothels in Great Britain and Ireland, whilst it facilitates their reformation, and at the same time protects the public health.

May we ask our readers to throw the mantle of charity over the sins of these women,—to remember that none are all evil,—to remember that many of them have been sorely tried by poverty,—to remember that, in all probability, their lives have been one long uninterrupted struggle against temptation, which, when assisted by poverty, it is hard, very hard, to resist,—to remember that, from many an erring sister, before she has fallen, "Hope had withering fled and mercy sighed farewell,"—to remember that the frown of the world and the unrelenting scowl of society have done more to confirm them in their wretched sin than many are aware of? We would solicit their own sex in their behalf; we would ask the high-born dames of our land to step forward to save a fallen sister from *total* destruction; we say, "Ye who are without sin cast the first stone at her."

CASE OF EXTRA-UTERINE FŒTATION EXISTING FOR AN UNKNOWN PERIOD, BUT UNDER OBSERVATION FOR TWO YEARS AND TWO MONTHS.

By Thomas Davis, M.D., M.R.C.S.I.,
Medical Officer, Manorhamilton Workhouse.

Bridget Devanny, æt. thirty years, admitted to the Manorhamilton Workhouse Infirmary on the 30th January, 1867. She was sent here from one of the Scotch Poorhouses.

The history she gave on her admission was, that she had been married at eighteen years of age, had borne a premature child about a year after her marriage. That her husband deserted her before her child was born, and she had not seen him since. For a length of time she had suffered from obstructed menstruation, attended with epileptic fits, for which she had been under medical treatment in Glasgow Infirmary, and subsequently in a Union Hospital. Her countenance was pale, inclined to a yellow colour, the lips showing the characteristics of epilepsy; the pulse weak, quick, and fluttering, but the heart sounds were distinct and normal, and the lungs apparently all right. On examining the abdomen when she lay on her back, I discovered a tumour in the region of the left ovary, over which she had been deeply cupped. The treatment she received was giving iron freely, with cod-liver oil and nourishing food. After a month or so, the fits became less frequent, but otherwise the medicine seemed to have no beneficial effect. Some weeks there would be obstinate constipation of the bowels. At other times profuse perspirations would be troublesome.

About the month of July, 1867, when she had been six months under treatment, retention of urine set in. I was then inclined to look upon it as hysterical, but, hysterical or otherwise, most troublesome it proved, as for several months she never passed a drop of water, except what was removed by the catheter.

In the month of September, 1867, whilst I was absent from home, my friend Dr. Shaw, who was acting for me, removed from the vagina what he supposed was a large polypus in a putrid state. After this there was no more trouble from retention of urine. Even at this period nothing unusual could be observed on examining with the speculum. The os uteri was close, presenting the appearance of a very small slit, and not congested looking; but, as far as I could judge, the uterus was pushed by the tumour towards the right. Singular as the admission may seem, I admit that it was only at this stage of the disease, and after the diseased or decayed mass was removed by Dr. Shaw, that the true character of the disease I had to contend against dawned on me. Very shortly after the removal of the fleshy mass from the vagina a new phase of the disease showed itself—namely, discharges of thin black blood from the umbilicus, which returned at intervals of three or four weeks, and thus continued from December, 1867, until the end of the year 1868, the quantity discharged being on some occasions marvellous, and during these periods some of my medical brethren who saw the case were inclined to look upon the discharges as vicarious. From time to time, during the early part of the year 1868, whilst these discharges were recurring, I removed masses of decayed flesh from the vagina, smelling most intolerably, and she constantly used lotions with chlorine iod.

On the 1st of July, 1868, she complained that something sharp was cutting her inside, and on examination of her vagina I found imbedded in the posterior wall of the vagina and extracted what proved to be the rib of a fœtus, which measured three inches in length, and half an inch in breadth. On carefully examining after its removal, the os uteri was still small and contracted, the bone seemed to have come from the left of the uterus, and the vagina looked injured in the posterior wall.

On the 24th of the same month, I removed in the same way, with very little difficulty, a portion of a fœtal femur, divested of cartilages, which measured two inches and a half. About four weeks afterwards she seemed to be suffering excruciating pain from some obstruction in the lower bowel, and on this occasion I removed from the rectum with my curved fore-finger a piece of flat bone, evidently one of the bones of a fœtal head, and in a few weeks more I removed in the same way a lumbar vertebra. From this date (the 20th September, 1868) until the early part of the month of January, 1869, I removed from time to time, sometimes with the aid of the speculum, and sometimes without it, various masses of decayed flesh and pieces of bones.

Whilst I write several of these are before me, with the dates of their removal marked: namely, a femur nearly perfect, a second less so, two ossa innominata, two ribs, several vertebra, and bones of the head, with some unrecognizable spiculæ.

From the date of the first removal of bone, the bloody discharge from the umbilicus diminished, and the patient's sufferings were mitigated, except when a spicula of bone became imbedded in the wall of the vagina, or was grasped by the sphincter ani, then her sufferings were painful to witness.

Early in January, 1869, it seemed as if her constitution had triumphed over all her ailments, the discharges ceased, the digestive functions became more regular, the appetite and strength improved, and she sat up daily in bed; but about the 1st of April, she was attacked with diarrhœa; the tongue assumed an aphthous appearance; her strength rapidly gave way; the character of the alvine discharges became more fœtid and unhealthy looking, and on the 19th of May she died.

A *post-mortem* examination thirty-six hours after death showed on opening the peritoneum a considerable quantity of straw-coloured serum, smelling abominably, with white particles of lymph or pus floating in it. The intestines all presented a dark red appearance, in some places approaching a purple colour. The uterus was of an average size, neither congested or displaced, as I expected to find it; but matted at the posterior part to the rectum, which was livid and black. I could discover no separate cavity where the fœtus had lain, it seemed to have been loose in the common peritoneal sac, and to have been of that form termed abdominal extra-uterine fœtation, although no trace of the fœtus now remained, except the marks of inflammation and ulceration which it had caused in the rectum and vagina.

The cause of death was registered as extra-uterine fœtation with ulceration of rectum.

◆

TO DISGUISE THE TASTE OF COD-LIVER-OIL.

The flavour of cod-liver oil may be to a great extent obviated in the following manner:—If we take the fish oil, spread it on toast, and grate over it a little smoked salmon, herring, or even ham, it may be eaten with no more effort than the salt mackerel which forms the standard dish of thousands of families.—*Pacific Med. and Surg. Journal.*

Demonstrator of Anatomy in the Royal College of Surgeons in Ireland.

ADELAIDE HOSPITAL.

Ulceration of stomach and induration of pylorus, with fatal result.

(Under the care of Dr. Barton.)

[From the Notes of Mr. Knaggs, Resident Pupil.]

A. B., a male, æt. fifty years, belonging to the better class of society, was admitted into a pay-ward in the Adelaide Hospital, April 20, 1869. He had been of intemperate habits, drinking whiskey freely,—he had suffered during the past six months from indigestion and from constant vomiting, the tendency to vomit being greatest after meals, and the ejected matter, which was usually fluid, having an intensely sour taste, being dark in colour and in excess of the quantity of fluid swallowed; he could always tell when he was about to have an attack of vomiting, by a peculiar sense of weight and fulness in the stomach, which gradually increased in intensity until it felt "as if a knife were cutting his entrails away." This pain could be relieved for a time by the use of a little carbonate of soda, but entire ease was never obtained until the stomach evacuated itself. The pain, from which at times he had complete relief, was generally referred to a point between the umbilicus and epigastrium, but was not localised there, wandering about the umbilicus, sometimes occurring in the small of the back, or shooting through the thorax up to the left shoulder. Exacerbations of pain generally took place about half an hour after the ingestion of food, and seemed to be relieved by the copious draughts of warm water which he swallowed in order to produce emesis, but which, even before causing vomiting, gave him much ease. Hot poultices to the epigastrium, and warm jars applied to his feet and back, also served to mitigate the pain. The presence of altered blood-cells and of the sarcina ventriculi in the vomited matter was readily detected by the microscope.

April 21st.—He was seen by Dr. Barton, who placed him upon a meat diet, given frequently, and in very small quantities. A linament composed of equal parts of the linaments of chloroform and belladonna was ordered to be rubbed occasionally over the region of the stomach; he was allowed small quantities of bicarbonate of soda, and one of the following pills twice a day:—

℞ Nitratis argenti, gr. iij.
Muriatis morphiæ, gr. i.
Ext. taraxaci,
Ext. rhei, āā. gr. xij.

Make six pills.

22nd.—During the night the patient threw up about two quarts of dark coffee-ground matter, the vomiting being preceded by the usual pain.

24th.—Early in the morning he suffered so much that, in compliance with his request for an emetic, the resident student gave him twenty grains of ipecacuanha, and about two pints of warm water, after taking which he vomited three quarts of dark fluid, and professed himself much relieved.

The pills were repeated, and a blister, two inches square, was applied to the epigastrium, and kept open by Albespeyre's paper; his bowels acted tolerably well. The vomiting not having abated, his food was changed, and he was placed upon milk diet, which evidently agreed with him much better, for from this time, the vomiting, although it did not cease, became less persistent. He continued much in the same state until May 1st, suffering from occasional severe pain and vomiting, which, showing no signs of greater alleviation, Dr. Barton ordered him to get no food by the mouth, but to be fed by means of enemata of beef-tea and brandy three times a day, with the view of giving the stomach complete relief.

He was ordered the following mixture :—

℞ Acidi nitro-muriat., fl. drs. ij.
Inf. calumbæ, fl. oz. xij. ♏

An ounce three times a day.

Ice was used to relieve thirst.

May 5th.—The vomiting has been less distressing until to-day, when he threw up three quarts of the dark fluid. He was seen by Drs. Head and Barton in consultation, and after a careful examination they agreed that there were no signs of malignant disease, and that the disease was either catarrh or chronic ulcer of the stomach. Ordered—

℞ Creasoti, gtt. x.
Muriat. morph., gr. ij.
Nit. argenti, gr. v.
Ext. conii, gr. xx.

Make ten pills, one three times a day.

With two ounces of the following mixture :—

℞ Acidi sulphurosi, fl. dr. iij.
Aquæ ad., fl. oz. xij. ♏

8th.—No vomiting since; patient comparatively free from pain, but getting weaker; pulse 95, moderately full. Nutrient injections increased to four times daily; mixture repeated. He was ordered chicken jelly.

9th.—Feeling the pain severe, and getting no benefit from hot jars and poultices, he swallowed two pints of warm water, which failed to cause vomiting, but gave much relief. The pain returned towards evening, and lasted until vomiting produced its usual good effect.

10th.—Much inclined to sleep.

℞ Creasoti, ♏vj.
Nit. argenti, gr. vj.
Muriat morph., gr. i.
Micæ panis qs., ut fiat massa.

Make six pills, one three times a day.

He had very little vomiting after this date, and no pain, but got gradually weaker, and was evidently sinking.

May 24th and 25th.—Suffered from an attack of diarrhœa; passed a quantity of dark brown matter by the bowel. This was readily checked, and from this date until his death, which occurred on the 29th of May, he suffered comparatively little, and took considerable quantities of nutriment.

A *post-mortem* examination was made the day after he died. The stomach was enormously distended; its walls were of a healthy colour and consistence, save at the immediate seat of disease. An ulcer about two inches in diameter, with thick irregular edges, existed at the lower part of the posterior surface of the viscus, near its pyloric end, where it is related to the pancreas; it had eaten completely through the coats of the stomach, and its edges were firmly adherent to the pancreas, which in this situation was somewhat indurated, and so cleanly dissected on the surface open to the stomach that its structure could be distinctly seen. The coats were much thickened at the pyloric end, and the valve itself so small and indurated that the point of the forefinger could with difficulty be passed through it.

MR. STAPLETON'S METHOD OF EXTENSION IN FRACTURES OF THE FEMUR.

In a letter which appeared in our issue of June 9th, Dr. Jacob, of Maryborough, takes occasion to say, that the method of extension in cases of fracture of the femur proposed by Mr. Stapleton, the account of which will be found in the Hospital Reports for the preceding week, is not new or original, and that he has been in the habit of using it in the Queen's County Infirmary for the last thirteen years. If Dr. Jacob had read the description of Mr. Stapleton's plan carefully, he would have saved himself some trouble, for he would at once have seen that the method proposed by Mr. Stapleton differs considerably from that which he claims as his own. Dr. Jacob attaches the extending weight *directly to the leg* by adhesive plaister, a plan which, of course, we were aware had been long in use, particularly in America, where Dr. Dugas claims to have originated it, although Dr. Jacob asserts that he is its inventor. Mr. Stapleton, on the other hand, hangs the weight *from the splint*, and attaches the leg to the fork of the splint by the loop of plaister. What advantages may belong to the respective plans of Dr. Jacob or Dr. Dugas, and Mr. Stapleton, we must leave others to decide; but Mr. Stapleton claims for his idea both novelty and excellence; and on the former point, at least, Dr. Jacob has failed to show that he is wrong, for we assert that in the work of Dr. Wales, to which reference has been made, there is no plan mentioned such as Mr. Stapleton has devised.

MERCER'S HOSPITAL.

Spina Bifida, and Analysis of the Fluid.

By Mr. Morgan, F.R.C.S.I.,

Professor of Anatomy, R.C.S.I.; Surgeon to the Hospital, &c.

On May the 11th a healthy countrywoman brought her child to me suffering from a very well-marked spina bifida. The boy was four months old; the tumour, which had been observed a fortnight after birth as about the size of a walnut, now had attained a great bulk, equalling a very large orange, with a slight attempt on a division across the middle; it was transparent and tense, and slightly abraded in parts. The child was remarkably well nourished and plump; no hydrocephalus whatever, and the fontanelles were normal. There was slight talipes of the equinus form in one foot, and on careful handling the outline of the deficiency in the spine could be ascertained. Carefully applied pressure by means of strapping was used, and after some days the size of the tumour had manifestly reduced, no inconvenience whatever being caused by the pressure. May 26. The child unfortunately got an abscess of the nates from an accidental cause, which obliged the treatment to be discontinued for some days, during which time the tumour enlarged considerably, and the skin began to thin and ulcerate; the child's strength also failed. The right hand showed signs of inturning. June 1st. I now tapped the tumour with a fine Pravatz's trocar, and took off two ounces of clear fluid, closed the wound, and applied careful strapping. As the child's strength was nearly exhausted, and as the mother determined to take it home, I was unfortunately not able to have a further examination. I had the fluid carefully analyzed; the result was—sp. gr. 1,000, reaction very faintly alkaline, it contained hardly a trace of albumen, a trace of soda and no potash salts, and was perfectly transparent and colourless.

FIBROUS TUMOURS IN PREGNANCY.

M. **Blot** believes that fibrous tumours increase in size during pregnancy, and diminish after labour.

EPILEPSY INDUCED BY SECTION OF THE SCIATIC NERVE.

Prof. **Brown-Sequard** alluded recently, in the Paris Academy, to the fact that section of the sciatic nerve induces epilepsy when the face is irritated at a certain point.

LUXATION OF THE HIP IN A YOUNG BOY.

Dr. **Tuck** (*Boston Med. and Surg. Journal*) recently related a case of dislocation of the right hip upon the dorsum ilii, occurring in a healthy boy six and a half years of age. He was playing horse, and fell, his companion falling upon him. The usual shortening of the limb and turning in of the toes were present. The head of the femur could be plainly felt upon the dorsum ilii. Ether was given, and reduction was easily effected by manipulation. This accident is noteworthy from the rarity of its occurrence in children.

THE SUPERANNUATION BILL AND MEDICAL EDUCATION.

Two of the questions which we have so often laboured to impress upon the profession and the public have at length found their way into the House of Commons, and made for themselves a lodgment which it will be difficult to disturb. The Medical Superannuation Bill (Ireland) has been read a second time, with the consent of the Government and the approving support of the Irish members of all classes. The Bill was introduced by Dr. Brady, Mr. Pim, and Mr. Hamilton; and it was gratifying to observe that the convincing arguments by which Dr. Brady, who moved the second reading, sustained the claims of the Irish Medical Civil Servants to a retiring allowance, were ably supplemented by Mr. Peel Dawson, who may be said to have represented the landed gentry on the occasion. Some difficulty was felt as to the source from which the superannuation was to be drawn—whether partly from the local rates and partly from the National Exchequer, as proposed in one of the clauses, or altogether from rates; but there was perfect and complete unanimity as to the principle—that a Medical Civil Servant was as well entitled to a retiring pension as any other Civil Servant of the Crown.

The great feature of the debate, however, was the striking and fearless speech in which Sir John Gray, Member for Kilkenny, developed the evils of the present system of examination for degrees, and the necessity for those reforms in the educational standard which the MEDICAL PRESS has so often insisted on, as the first and most essential step towards securing for the medical practitioner that high social status which is due to the skill, to the self-sacrifice, and to the services conferred on the community by the educated medical man. In the course of a long and exhaustive speech,—which we hope to see fully reported and republished, in which the services, the risks, the never-ceasing labours, and the starvation pay of the Medical Civil Servant were forcibly contrasted with the high status, princely emoluments, sinecure offices, and luxurious pensions provided for the Legal Civil Servants of the Crown—the Member for Kilkenny arraigned the Government, charging it with gross abandonment of its duty to the public in seeking to degrade, by beggarly stipends and official neglect, that profession, the members of which are ever sacrificing personal care, family comfort, health, and even life, in the gratuitous service of the poor and the afflicted. But, while thus boldly pointing out the misdeeds of the Government, he did not spare either the licensing bodies or the Medical Council, both of whom have been so impenetrable to public opinion, to the demands of the Medical journals, and of the heads of the profession. Sir Benjamin Brodie in London; and Graves, Carmichael, and Sir Dominic Corrigan in Dublin, have long since demanded that the parrot system of examination be flung aside, and that, instead of grinding and cramming in order to "pass," by committing words to memory, the student should be coerced by a practical examination to become acquainted with *things* as well as *words*—with the features of disease as they appear to the careful observer of nature, not with the mere names of symptoms as crammed into a man's ears by the grinders. Sir William Jenner and the Medical Teachers' Association of London have again and again insisted on the application of this principle, and demanded that the examination as to a man's knowledge of disease should be tested practically in the hospital and in the dispensary, as the knowledge of anatomy and chemistry now is, in the dead room and in the laboratory; or rather by presenting the subject and the chemist in the examination hall for the inspection and manual operation of the candidate. The Report of the society over which Sir William Jenner presides was largely used in the debate, and lost none of its force by the manner in which it was introduced. The necessity for reform in this vital point has now become a question with the Legislature. It has not passed from the halls of the profession, nor from the pages of the medical periodicals of the day; it has but extended to the council-room of the nation; and if it be followed up with the vigour with which it was commenced, we hope ere long to see it become a Cabinet question, as it is now a Parliamentary one. We have often warned the Universities and the Colleges that the time was not far distant when the public must interfere for its own protection, if they would not act for the honour and elevation of the profession. Who can doubt that *that time has now come* who read, as thousands did last week in the columns of the daily journals, that a member of the Legislature asserted in his place in Parliament that a man who was well crammed by a grinder could obtain a licence to practice "who never put his hand on a human pulse, who never bandaged a limb, opened an abscess, or placed a stethoscope on the chest of a diseased patient?"

We can well imagine the sensation produced amongst some of the purse-proud and aristocratic members, who heard the terrible truth for the first time, and who, up to then, fancied that medical reform was a matter of concern to the poor only, and had no interest for them. It was difficult, no doubt, for men who gave the profession a "log" when we asked for "a king," to believe that this state of things could exist after the "Medical Council" had been formed, and met and held conferences during ten successive summers. But there was no refuting the incontrovertible truth so forcibly expressed by Sir John Gray, who cited authorities in abundance, from Sir Benjamin Brodie and Graves—who speak to us from their tombs—to Sir William Jenner, and the "distinguished Dublin Professor," who was listening to the debate, whose opinion Sir John Gray transferred from the quiet pages of the medical journals to the halls of Parliament, whence they will penetrate every home in the empire. That this was not done in vain we gather from the assurance of a Cabinet Minister (Mr. Fortescue), who confessed his alarm at the startling facts and the more startling proofs adduced, and added that it was impossible for Parliament to overlook such a statement. The Medical Council meets in London this week. There are men on that Council ornaments to science, to their profession, to their country, and to their age. We ask them, for the honour of the profession and the good of their kind, not to overlook the fact that the system of examination is now under the consideration of Parliament and of the Government, and that it is their duty to keep pace with the age. The views propounded by the MEDICAL PRESS AND CIRCULAR, and many of our contemporaries —by Jenner and Corrigan, and the President of our two great Surgical Colleges, have found an able and eloquent exponent in Parliament in the person of Sir John Gray, and we confess that we feel not a little, and we hope not an unreasonable pride, in the near prospect of the realization of a sound education, a practical examination, and a full recognition of the status and services of the medical practitioner, for the consummation of which we have so long laboured.

◆

RETIRING PENSIONS FOR IRISH POOR-LAW MEDICAL OFFICERS.

THE Poor-Law Medical Officers' Superannuation Bill, which received its second reading in the House of Commons, has been a subject of such earnest consideration to the profession in Ireland that a history of the progress of the measure from its origin to the step, which we hope we may call its completion, will not be unacceptable to our readers.

The omission of all reference to compensation for medical officers whose dispensaries were abolished by the Medical Charities Act of 1851 compelled many men who were already old or worn out in the public service to retain their offices under the new system. In a few years some of these gentlemen, when unable from increased age and infirmity any longer to discharge their duties with efficiency, were obliged to resign their offices, and the want of a provision to enable the Boards of Guardians to give them superannuation became evident to all. Other officers employed under the Poor-law were in the same predicament, and Boards of Guardians humanely accepted the weak and inefficient services of these gentlemen rather than turn them off without provision for their few remaining years. Agitation upon this subject once commenced, soon became very general through the country, and the Irish Medical Association, as well as the other medical protection societies through the country, at once took up the matter on behalf of the Poor-law and dispensary medical officers. The assistance of the Colleges of Physicians and Surgeons was sought and readily granted. Deputation after deputation was sent to each succeeding representative of Her Majesty in this country. The aid and sanction of the Poor-law Commissioners were procured, and at length our hopes of success were raised to the highest pitch by the introduction of Peel's Bill for the Superannuation of Poor-law Officers. The provisions of this Bill were not exactly as we had expected, and some anxiety was created by the introduction of the well-known words of limitation describing those entitled to the advantages of the Bill as officers whose whole time was devoted to their public duties. Sir Robert Peel, who had the charge of the Bill, was appealed to, and, to the surprise of all, it was ascertained that medical officers of workhouses and dispensaries were excluded by those words. Great indignation was felt by the entire profession at the slight thus thrown on their brethren, and much exertion was made use of to prevent the Bill passing without an amendment. Successful for that Session, its progress was stopped. Next year, however, this Bill was again introduced, and with the fatal words unaltered. The Association now made every exertion, and sent a deputation to the Irish Members of the House of Commons. A division of the House took place upon the clause, and was lost by a majority of 13.

The Association, however, did not despair; but, confident in the truth of their statements that the dispensary medical officers' whole time was justly to be considered as devoted to their public duties, they continued with renewed energy their agitation of the subject by deputations, public meetings, and circulars to members of the House of Commons on the subject. Sir Colman O'Loghlen having soon after introduced a Bill for the superannuation of other civil officers, great exertions were again made by the medical associations to have its provisions extended to the Poor-law and dispensary medical officers. The assistance of the College of Surgeons was procured, and that body sent a deputation to assist the Secretary of the Medical Association in having the medical officers included. This was effected; but the Bill was withdrawn, fatal objections having been raised to its other provisions. The deputation was most useful, however, in having won over several members of the House who had been opposed to the medical officers' superannuation. The agitation was continued; and it having been suggested by one of the Chief Secretaries upon whom a deputation waited to urge the Government to introduce a Bill that we should not wait for Government to do so, but get it done by a private member, the Royal College of Surgeons liberally instructed their law adviser to prepare a Bill, and had the same intrusted to Dr. Brady, Mr. Ion T. Hamilton, and Mr. Pim, for introduction to the House. This has been done; and the interval between the first and second reading of the measure has been made the best use of by the associations and numerous individual members through the country in procuring the support of the Irish members of the House, so that on the second reading taking place not a single member spoke against it. The College of Surgeons have sent their president and secretary to urge forward this measure, and Dr. Darby, of Bray, Vice-President of the Irish Medical Association, with the Secretary of the Association, have likewise been in London securing the second reading of the Bill.

Thus this useful measure has been, after years of constant and persevering agitation on the part of the medical associations of Ireland, pushed forward through its second reading to a committee of the House, whose sole object is to put its provisions in Parliamentary form. Too much praise cannot be given to Dr. Brady, the promoter of the Bill; his clear and able statement of the claims of the dispensary medical officers at once won over the hesitating, and overcame all opposition. The Irish Chief Secretary, who had kindly received the President and Secretary of the College of Surgeons, and the Secretary of the Irish Medical Association, who had gone there as a deputation, gave also an audience the following day to Dr. Darby, Vice-President of the Association, who had liberally come over to assist the deputation.

◆

OVERPOPULATION CONSIDERED AS A PROMINENT CAUSE OF MISERY AND EARLY DEATH.

By Charles R. Drysdale, M.D., M.R.C.P., F.R.C.S.,
Physician to the North London Consumption Hospital, Hampstead, &c.

Several distinguished writers in the Medical Press and Circular have lately done me the honour to question the accuracy of the theory of population, which I have on one or two occasions brought forward, in order to account for the excessive deaths of the poorer classes, and especially the frequency of cases of typhus fever, consumption, and infantile mortality, observed to occur among the ill-fed and ill-homed poor, in comparison with those seen among their more comfortable and richer brethren. "It is but too true," says Levy, in his admirable work on Hygiene, "that the duration of life is by no means equal in the different classes of society. Some there are which attain, on an average, seventy years of age; and others which do not get beyond forty-five years. The extent of the oscillation reaches to one-third of human life." According to Lombard, of Geneva, easy circumstances add 7·5 years, and want of comfort subtracts 7·5 years from the mean of life. Again, M. D'Espine, in his essay on the "Influence of Easy Circumstances and Poverty on Mortality," says that, when we can separate the portion of any population in easy circumstances from the others, so as to consider each separately, the figure of those in the better classes compared with that of the whole population is found to be at least ten years longer. It has also been shown by D'Espine, in the Annales D'Hygiene of 1830, that tubercular disease occasions sixty-eight deaths in 1,000 among the rich; and more than 230 in 1,000 among the poor. Villermé, too, showed that, in the second quarter of Paris, where non-taxed lodgings form 0·07 of the whole number, the mortality was one in sixty-two; whilst in the twelfth quarter, where the poor live, and where 0·38 of the lodgings were untaxed, the mortality was one in forty-three.

My antagonists will, perhaps, admit the truth of these facts, and perhaps, go along with me so far as to grant that poverty, or want of the comforts and necessaries of existence, is, as we should easily presuppose it to be, one of the greatest foes both to human health, longevity, and happiness. But these gentlemen here part company with me; they all say, "Granted all this; but your account of the origin of poverty, as being a consequence of over-rapid multiplication, or large families, is not a true one." Of course I take my adversaries' best case, and am by no means prepared to attack them, as they seem to do me, by interjections and exclamations. It has been well said, that it is impossible to argue with an interjection, such as the "Sin of Malthus," and other rhetorical expressions which, I must say, I wish writers would not introduce into serious arguments in a serious and important profession like ours. Not that I desire to blame anyone for making use of any expression which might help his case: only, I would remark, that the dictum of Cicero seems to me the best, viz, that we should always attack our opponent's strongest, not his weakest points. And the applause of the ignorant, I am sure, cannot satisfy my able brethren.

The strongest point, then, in my case, is the following:—I assert that the existence of almost all the poverty we see around us, the immense infantile mortality among the poor, the excess of death from consumption and fever among the poorer classes, is accountable for deductively, when once we have admitted the law discovered by Malthus in the beginning of this century, and since agreed to by Ricardo, Chalmers, the Mills, Senior, Whately, Darwin, Huxley, and a host of eminent writers, which is—That the human race has a power, when supplied with plenty of food and other necessaries of life of doubling in periods which have been calculated diversely at from fifteen up to thirty years. On this point I referred my readers to the article on Population in the "Encyclopædia Britannica," 1840: but as I daresay they will neither have the time, nor perhaps opportunity, to read that essay, I will endeavour to summarize what I humbly think to be the essence of this most pregnant of all questions in its consequences on human happiness.

Mr. Malthus, resting upon the most recent censuses of America made at the time he wrote (toward the end of last century), thought to put himself out of all dangers of contradiction, when he asserted that, when population is not arrested by any obstacle, it goes on doubling every twenty-five years, and increases in a geometrical ratio. It would have been quite sufficient if the fact of doubling in twenty-five years had been well proved but once, without counting immigration, in order to prove the assertion of Malthus. Now-a-days the number of cases is so great that to deny the law above stated seems to us to deny evidence. Statistics now give us eight official decennial censuses of the United States, including more than a half century, more than twice the Malthusian period of twenty-five years, between 1790 and 1860. In 1790, the United States were free and constituted: they have not since then ceased to live under the same government; no extraordinary event came to them to thwart the ordinary progress of events: and, more than this, the American population, not having as yet attained the limit of its disposable territory, or of its subsistence, has continued to obey the law pointed out by the censuses taken before this century, and which served Malthus with data for his theory. We have here one of the most remarkable facts relative to population, both for its accuracy and for its continuity. According to the different official censuses, the progress of the population of the States has been, in round numbers, in 1782, 2,389,000; in 1790, 3,929,000; in 1800, 5,305,000; in 1810, 7,239,000; in 1820, 9,638,000; in 1830, 12,866,000; in 1840, 17,062,000, in 1850, 22,806,000. If we divide the cypher of 1840 by that of 1790: that is, 17,000,000 by 3·9 millons, we find that the population more than quadrupled in fifty years. If we divide that of 1850, (22·8 millions) by that of 1,800 (5·3 millions) we find that the population has again quadrupled in the two first periods of twenty-five years of this century. If we compare periods of twenty years only, we see that the population almost doubled from 1800 to 1820; from 1810 to 1830; from 1820 to 1840; and from 1830 to 1850. Mr. Place, in a work entitled "Illustrations and Proofs," London, 1822, has shown, that up to 1783, war and different circumstances were obstacles to immigration into the States, and took from them more than Europe furnished. The French Revolution was an occasion of emigration to America; but this movement was soon interrupted by the war of 1793, and since that epoch up to the peace of 1815, Europe furnished but few emigrants, almost exclusively from England.

Adam Seybert, of Philadelphia, in 1818, says, "We believe that the population of the United States have been much augmented by emigrants from Europe. We have no authentic document; and must be content with simple estimates. Immigrants arrive principally from Great Britain, Ireland, and Germany. In 1794, Mr. Cooper estimated the number of immigrants at 10,000. In 1806, Mr. Blodget said that according to the registers and estimates worthy of belief, this sum was not annually above 4,000 for ten years past. In 1794 there was in Great Britain a great tendency to emigrate to the States. Admitting that in 1794 there arrived 10,000 strangers; we cannot grant that an equal number arrived in any year before or after up to 1817." Finally, Dr. Seybert, after having declared that he only looks to facts, without thinking of any theory to be proved, arrives at the conclusion, that the number of 6,000 emigrants established annually in the United States, from 1790 to 1810, is the greatest number that can be supposed. Hence the population evidently more than doubled, not counting emigrants, and by the mere power of fecundity, in the twenty-five years, beginning 1790 and ending 1815.

Now, if we consider this fact, it will be evident to us how important it is in order to account for the phenomena of society going on around us. Say that there are 30,000,000 inhabitants in Great Britain at this time. Well, if these 30 million were in the same favourable circumstances as the population of the States from 1790 to 1815, the population of Great Britain might be in 1895 no less than sixty millions. It is this *tendency* to double in twenty-five years or less, that will be found to account so well for the misery of the less educated, and therefore less thoughtful classes. Did we live in the Western States of America, it would be possible to live entirely without any uneasiness as to the numbers of children to a family; but in Europe, the *classes* which habitually produce large families usually fall down to the bottom of society, and the average of the life-time of these classes is thereby lowered by privations of all kinds, which cause fevers, consumption, and infantile mortality. You blame the provident habits of the French peasantry, because they will not consent to breed down to the level of the Irish cottier. But is it not better to prevent death and misery, by proportioning the size of the family to the means, than to trust to mere chance and exportation as a last remedy for starvation? Whether do you elect to take the side of the illustrious J. S. Mill, and say, "Little improvement can be expected in morality, until the producing of large families is regarded with the same feelings as drunkenness, or any other physical excess; but, while the aristocracy and clergy are foremost to set the example of this species of incontinence, what can be expected from the poor?" Or will you rather take the part of the Roman Catholic priesthood, who are enjoined to represent to their penitents before giving them absolution, that all such care as to the number of children they may have is contrary to the doctrine of the Church, and as "*le plus damnable des péchés mortels?* For my part, caring more for the happiness and health of men, than for the existence of such authority, which is now fast getting into disrepute, I elect to follow the teachings of Mill and others, and to prefer long life and freedom from poverty for European nations to any mere dogma, which is, in my opinion, absolutely false, and destitute of any scientific basis. The rate of increase of the French population is the slowest in Europe. At the census of 1851, the rate of annual increase shown was only 1·08 per cent. in the five years, or 0·21 annually, and at the census of 1856, 0·14 annually: so that, as M. Lavergne says, "Population has almost ceased to increase in France." Even this slow increase is wholly the effect of a diminution of deaths; the number of births not increasing at all, while the proportion of the births to the population is constantly diminishing. This slow growth of the numbers of the people, while capital increases more rapidly, has caused a noticeable improvement in the condition of the French labouring class. And, on the other hand, it appears to me, that in this country our poor were never worse off than at present, and we are all in low spirits about this.

"Unhappily," says Mr. J. S. Mill, "sentimentality, rather than commonsense, usually presides over the discussion of these subjects and while there is a growing sensitiveness to the hardships of the poor, and a ready disposition to admit claims in them upon the good offices of other people, there is an all but universal unwillingness to face the real difficulties of their position, or advert at all to the conditions which nature has made indispensable to the improvement of their physical lot. Discussions on the condition of the labourers, lamentations over its wretchedness, denunciations of all who are supposed to be indifferent to it, projects of one kind or another for improving it [emigration is the cry of to-day], were in no country and no time of the world so rife as in the present generation; but there is a tacit agreement to ignore the law of wages, or to dismiss it in a parenthesis with such terms as 'hard-hearted Malthusianism;' *as if it were not a thousand times more hard-hearted to tell human beings that they may, than that they may not, call into existence swarms of creatures who are sure to be miserable, and most likely to be depraved.*"—("Political Economy," Book ii., Chapter xi.)

Such are the remarks of the greatest political economist and thinker of the age, a gentleman who is enshrined in the hearts of the *élite* of the working classes because of his steady and ardent desire to raise the condition of the workers of *all classes*, by the overthrow of all unjust land laws, primogeniture, or other selfish monopolies. To say that political economists are aristocrats and callous to the sufferings of the poor betrays an utter ignorance of the writings of Mr. J. S. Mill. He is the champion of all human rights, however unrecognized by others.

One word in reply to a respected member of the profession in Brighton. He asks me what are the details of French slow increase of numbers; how this is accomplished? I answer that documents fail me in this respect. Dr. Routh (*Medical Mirror*, June 1, 1869) has shown that in some manufacturing towns of France the number of children to a family is much over the average of the rural districts and small non-manufacturing towns. But, with the exception of these remarks, I cannot refer my querist to any work giving the information he asks me for. Suffice it to say that the French population is stationary, and that poverty is there far less prevalent and distressing than it is in this country, although Malthus and Mill have lived and taught in our midst.

Another querist says, how do I make out that prostitution is the result of large families? Of course he knows that prostitution is in nine-tenths of the cases the effect of poverty of the woman (Duchatelet "Sur la Prostitution"); well, then, if poverty be caused, as I think, by large families in European States, the question is answered. And with respect to Doubleday, the answer that I made, that the families of the aristocracy are very large, was made by McCaulay to Mr. Doubleday in an essay in the *North British Review*, to which I refer all who may be captivated by the idea that poverty is the cause rather than the effect of large families. I have given these views *in extenso* here, because I hold that all questions of State medicines, without the law of population being considered, are *mera palpatio.*

◆

DR. RICHARDSON'S LECTURE AT THE ROYAL POLYTECHNIC,

TUESDAY, JUNE 22, 1869.

BEFORE commencing his discourse, Dr. Richardson apologized for not having answered the many correspondents who had written to him on the subject of these lectures, which appear to have created greater interest than any he has previously delivered; but while thanking them for their suggestions, references, and other information, by which he hoped to profit, he must state that to answer three or four letters per day was a labour absolutely incompatible with the preparation of his discourses.

Entering upon the subject of the lecture, he combated the notion that the brain or the nerves were electrical machines or galvanic batteries from which the forces in the body were derived. If the electrical theory of life were in the main correct (a theory which was in itself questionable), the body must be looked at in its entirety as an electrical machine, no particular part of it being in any way the special centre of force, any more than any particular portion of the machine he was about to experimentalise with was the source of its electrical power. The machine must be taken as a whole, and so must the body. The theory which made the nerves both the generators of electrical force and the conducting mediums of that force was absurd. That they did not act as the conducting agents, in the same way, at least, that a wire acted as a conductor of the electrical current, he had shown by his experiments in a former lecture, when, on freezing particular portions, either of the brain or the spinal cord, sensation was deadened in the immediate neighbourhood of the part acted upon, but the transmission of sensation to parts beyond was in no way impeded. If one part of the body acted as a conductor of electricity rather than another, some experiments he was about to show would point rather to the blood as the conducting medium.

Proceeding to speak of some of the effects produced by lightning on the human frame, he said it seemed to bear out the theory that a certain sensible interval of time was occupied in transmission of sensation to and from the brain. Persons who recovered, after having been struck by lightning, were often entirely without any recollection of the accident. To show that this was not due to any special effect of the lightning, but merely to the suddenness of the shock, he instanced the case of a lad who, climbing along a wall to take a bird's nest, fell on his head, and was taken up insensible. In this state he remained four days, but afterwards quite recovered. Up to the present time, however, he has no recollection of the accident; the last he remembers on the occasion is the grasping of an egg in the nest. The frequent absence of pain in cupping was a further instance; and the lecturer asserted his conviction that surgical operations might be performed with such rapidity as to prevent the feeling of pain. Not only might it be expected that an incision could be made painlessly, but a limb might be removed without any sensation being experienced by the patient.

With regard to metallic marks left on the bodies of persons struck by lightning, it appears that there can be little doubt that such marks are actually produced. A reliable case is narrated in a medical journal of a lady on whom the mark of a gold chain she wore round her neck was left when the chain was fused by a flash of lightning, the mark having a golden metallic lustre. Fine wires of gold, silver, zinc, copper, and brass, passed in front of a sheet of white paper, were then fused by a discharge from a Leyden jar, and in each case a special mark was left on the paper. A white rabbit was also exhibited, down whose back a brown streak had been produced by the fusion of a wire in the same manner. The rabbit in this case was not killed by the shock.

Experiments were next made illustrative of the conductive power of the blood. A current from the battery was passed through blood inclosed in tubes from which the air was carefully excluded. The standard tube contained blood in nearly its normal state, and with it were compared tubes of blood mixed with nicotine, alcohol, ether, and other substances. The result showed that the normal blood was in most cases the better conductor; congealed blood, however, surpassed it in conducting power. Special attention was called to the fact that blood mixed with water was a far worse conductor than the normal blood—a fact adverse to the theory that the serum or watery part of the blood is the conducting medium, rather than its other constituents. Electrical discharges passed through arterial blood produce the purple colour of venous blood; and by means of tubes, in which blood was made to circulate, this discolouration could be made manifest, and its immediate removal by oxydation from peroxyde of hydrogen exemplified.

Lightning, when it does not actually destroy life, appears capable of producing six different forms of disease both in men and animals: 1st, feverish excitement; 2nd, epilepsy; 3rd, apoplexy; 4th, catalepsy; 5th, paralysis; 6th, blindness. Instances were given illustrating all these various classes of disease; the most remarkable were the following:—An instance of apoplexy, where an Englishman having received a shock from an electrical discharge, which struck the ship he was sailing in, killing some of the men, immediately showed all the symptoms of apoplexy, but was relieved by copious letting of blood. A remarkable instance of catalepsy was that of a butcher, who was struck by lightning while driving in his cart, and taken home insensible. On recovering consciousness he was extremely weak, and gave evidence of cataleptic symptoms. He gradually declined, refused food, and was at length in such a state that he was supposed to be dead, and was actually laid out preparatory to being placed in a coffin. During this time he was quite conscious of all that was going on, but it was with the greatest difficulty that he managed by a slight movement of the hand to indicate to those around him that he was not dead. On the discovery being made he was fed, gradually recovered, and was at length perfectly restored. Paralysis, curiously enough, generally affects the lower limbs both of men and animals, even though the upper parts of the body be struck. Lightning may produce blindness in various ways and under several forms. It may be occasioned by the flame discharge, or by the shock, or merely by looking at a flash of lightning. It is sometimes produced without the appearance of the eye being in any way affected outwardly. At other times the cornea, corocoid coat, or other portions of the eye, are distinctly seen to be injured. A peculiar form of injury to the cornea was illustrated by an experiment upon a sheep's eye. The eye of an animal recently killed, and while still in the head, was subjected to a discharge, and showed distinctly a whitening of the cornea, as if the vitreous humour had been fused.

The lecturer concluded by asking those of his audience who cared to hear another lecture to meet him that day three weeks.

SCOTLAND.

ENDOWED HOSPITALS BILL.

In the House of Commons on Thursday last, on the order of the day for the House going into committee on this Bill,

Dr. L. **Playfair** rose to move that the House go into committee on the Bill on that day six months. He contended that Scotland ought to have a scheme as large in principle as that which had been granted to England. These hospitals or schools, more especially those in Edinburgh, were richly endowed; but the education given in them unfitted the scholars for active life. The present Bill was merely permissive, and offered no radical reform for the future. The great defect of it was, while they were concentrating education under one Minister it proposed to create a new educational department. It was quite true that these institutions had shown some disposition to reform themselves, but their scheme of reform was most limited and utterly inadequate. All that he asked of the noble and learned lord was not to pass the Bill through committee that night, but to wait and see whether the House sanctioned the Bill brought into the Lords for establishing a Board of Education for Scotland.

Mr. **Campbell** seconded the amendment, and expressed a hope that effectual means would be taken for developing the latent benefits which these institutions might afford.

Mr. **M'Laren** desired to see the Bill improved, especially as it was doubtful whether a stringent measure could be passed during the present, or even during the next Session.

Sir E. **Colebrooke** considered that the efforts of the Government were not equal to the exigency of the occasion.

Mr. W. E. **Forster** referred to the ample funds existing in Scotland applicable to educational purposes, and the willingness manifested by the managers to apply them efficiently. It had been objected that this measure being passed might prevent the enactment of a more perfect one; but it should be borne in mind that the Bill was only to continue for two years and a half, and if the institutions were not satisfactorily reformed in that time a compulsory measure might then be passed by Parliament.

Mr. **Parker** observed that this Bill did not profess to deal with the whole question of secondary education, but was a measure framed in accordance with the views of the managers of some of the institutions, and would not, if passed, interfere at all with a more effectual and extended one being brought forward by the Government on a future occasion. What was really wanted in reference to educational establishments, both in England and Scotland, was a more perfect organisation, so that the parts might work better together.

The **Lord Advocate** thought that the hon. member for the University of Edinburgh (Dr. Playfair) had misconstrued the object of this Bill. It was not intended to deal with the whole question of education in Scotland. What he looked forward to was a regular scale of education supported by public funds, but it would be premature at present to frame any such a system. The present measure was to enable the managers of the institutions in question to propose schemes of reform themselves—a thing which he knew many of them were anxious to do. He hoped the House would now go into committee on the Bill.

After a few words from Mr. **Kinnaird** in favour of the motion,

Dr. **Playfair** withdrew his amendment, and the Bill passed through committee.

Notes on Current Topics.

The Penitence of the "Lancet."

Last week we discharged a rather unpleasant duty, but one which had become imperative by the perseverance of the *Lancet* in attacking gentlemen for doing as it has done for years. We succeeded in discharging this duty in a manner that has overwhelmed us with manifestations of approval. The article in which our contemporary was exposed has created quite a sensation, and led to an extraordinary sale of that number. Under these circumstances it would, perhaps, be ungenerous towards the offender not to acknowledge the half repentance evinced. The *Lancet* has not, indeed, answered the query contained in our article, but has modified the extent of its advertisements and their sensational character. Instead of the usual eight or nine advertisements, last Saturday's *Times* only contains three. The key of the "trumpeting," as our contemporary calls advertising, has been changed, and the "startling" statements to which we directed attention revised. So far so good; but we did not take up this matter with any other view than to vindicate right. The *Lancet* substantially admits the justice of our rebuke, and will, we hope, refrain in future from its bad practice of attacking individuals. As we exhibited last week the facsimiles of its sensation advertisements, it is but fair to show our readers its modified ones. Here they are:—

> THE LANCET, of Saturday next, July 3, commencement of a new volume. Subscription 17s. 4d. half yearly, stamped, or 7d. weekly, unstamped. To be obtained of all booksellers and newsmen. Office, 423, Strand.

> THE LANCET, of this day (Saturday), June 26th, contains:—An Original Lecture on the Nervous System, by Dr. Brown Sequard—Clinical Notes on Syphilis, by Dr. J. K. Spender—A Case of Amputation of the Lower Limbs, by Dr. Carmichael—Leading Articles on the College of Surgeons' Election, Hospital Apparatus, &c. —Medical Annotations—Special Articles and Correspondence on Current Medical Topics. Price 7d.; stamped 8d. Office, 423, Strand, and of all booksellers and news agents.

> THE LANCET.—No. 1 of a New Volume, Saturday next, July 3. Order at any bookseller's or newsvendor's, or from the office, 423, Strand.

It will be particularly noticed that the author's names before their works, so strongly condemned by our contemporary, but till now regularly used, are dropped, as is the magic formula "*see Lancet.*" Is this the sign of penitence, or have the gentlemen advertised themselves taken fright? If so, another contemporary will probably follow suit.

The 1st of July, 1869.

THE COLLEGE OF SURGEONS—THE MEDICAL COUNCIL.

THIS is to be a red-letter day, if the hopes so freely expressed are realized. The Fellows of the Royal College of Surgeons of England are to inaugurate a new era. Three liberal men are to be elected into the Council of that College, and the Fellows are to maintain their right to question those who seek their suffrages, and debate their own affairs in their own Hall. The time is so near that we can scarcely do other than bid God-speed to those who have resolved thus to do their duty to themselves and their profession.

The same day is to witness the assembling once more of the General Medical Council. Will the coming session of that body eclipse its predecessors? Many hope that the Council will return to a consideration of its own constitution, and that its deliberations will take a more practical form than they have hitherto done. Some Councillors are weary of the talk that has led to nothing, and resolved to see if action cannot be substituted. Still there is a heavy weight of satisfied men who seek no more than to go on in the old useless routine. The profession is awaking to the question—everywhere there are signs of this; and the Council will be called to account by it, whose money it so freely expends. Let the Council enter heartily on the work of reform, and it has a noble career. Let it again refuse, and it will have been proved unworthy of its opportunity, and the sooner it is shelved the better.

The late Railway Case.

SOME time since we commented on the case in which a jury had awarded £4,000 as damages to a gentleman who was injured by an accident on the Lancashire and Yorkshire line, and hinted that further litigation would probably ensue. This has come to pass, and in the Court of Common Pleas, last Thursday, the damages have been reduced to £2,000, by plaintiff consenting to accept the Judges' decision as to amount, should they be of opinion that a new trial must be granted on the ground of excess. Justices Willes and Smith concluded a very careful judgment by saying the case must go for a new trial unless, as proposed by plaintiff's counsel, the sum above-named were accepted. In point of law, no doubt, this is all right enough; but we must admit that, so far as the medical evidence is concerned, it leaves the question raised in as unsatisfactory a state as ever. No opinions could be more opposite than those expressed by medical men on the former trial, and we must regret that there is now no means of further sifting the opposing views of the surgeons engaged. As we have before suggested, it might go hard with any student who stated in his examination what either side swore to in this case.

Synthesis of Acids.

M. WURTZ has laid before the Paris Academy of Sciences a new method which enables him to effect the synthesis of a number of aromatic acids, or rather of their ethers. It consists in heating a bromide or an organic chloride by chloroxycarbonic ether in presence of sodium amalgam. This last metal taking up the chlorine or bromine, the ether of the organic acid is isolated. By the help of this method M. Wurtz has attempted to convert bromized benzoin into benzoic acid, and bromized tolvème into toluic acid.

Effects of Compressed Air.

DR. G. VON LIEBIG has recently completed some experiments on this subject, and has thus summed up his conclusions:—

1. The number of respirations under the effect of a high pressure, and after the subject has become accustomed to this condition of respiration, do not differ much from those produced under ordinary circumstances.
2. The quantity of air respired does not differ much under the various modes of respiration.
3. The quantity of carbonic acid eliminated under the two conditions is nearly identical.

A Statue to Boerhaave.

THE subject of the propriety of raising a statue of Boerhaave at Leyden has been under discussion, and the Royal Academy of Medicine of Belgium have unanimously supported the movement, and decided to take part in the subscription, which, it is expected, will be opened. They have also ordered that a deputation of its members shall assist at the inauguration of the monument.

The Report of the Water Commission.

THIS long-delayed Report has at last appeared, and exactly fulfils our predictions. Some months ago we ventured to prophesy the conclusions which the Commissioners would probably adopt. We were then immediately contradicted in a rather unceremonious manner, and the *Lancet* endeavoured to make capital for itself at our expense in a paragraph no *gentleman* could have penned.

We took no notice at the time, but resolved to wait for the appearance of the Report, as our justification. The Report, as issued, is in every particular such as we predicted, so that our forecast is most conclusively confirmed. After this the *Lancet* will, perhaps, believe that we are quite as capable as itself of forming an opinion on such matters. At any rate, we hope it will not again so forget itself as to give us the lie direct. Its intense prejudices on these questions may blind it to facts, and prevent it seeing what is obvious enough to those whose reason is not so obscured by foregone conclusions and anxious desires. This may be an excuse for the manner in which it has misled its credulous readers, but by no means justifies the rudeness of which it was guilty. Ignorance is one thing—insolence another.

High Rate of Mortality in Glasgow.

The monthly return for the past month shows the entire number of deaths that have occurred within the fifty-four sanitary districts into which the city is divided to be 1,440. This, upon a basis of population presumed to be half a million, shows the death rate in the month of May to be 34·76 per 1,000. That of London generally runs about 25 per 1,000, and a healthy country district about 17. On this showing, the mortality in Glasgow is more than twice that of a good country district, and thirty-nine per cent. more than that of London.

The Scientific Societies of Dublin.

At a meeting of the Council of the Royal Dublin Society, held on Thursday, the Marquis of Kildare, V.P., in the chair, a report from the Committee of Practical Science was read, in which the success of the late series of afternoon scientific lectures was adverted to. The report then proceeded as follows:—"The committee consider that it would greatly tend to advance science in Dublin, were the several societies who are unprovided with suitable accommodation permitted to hold their scientific meetings on the society's premises; and with that view the committee suggest that, in accordance with the recommendation of the commission on scientific institutions, the Council will afford accommodation for such societies to hold their meetings on the premises of this society, subject to such arrangements as may be mutually agreed upon, the independence of the several societies being strictly preserved." With reference to the latter passage in the report it was resolved that the Council approve of that part of the report just read which relates to the proposal for certain societies in Dublin to hold their scientific meetings on the premises of the Royal Dublin Society, and that it be referred to the Committee of Practical Science to make arrangements with such societies as should apply for the privilege relative to the meetings, and to report thereon to the Council. A deputation from the Natural History Society of Dublin attended, who represented to the Council that that society would be glad to avail itself of the opportunity of meeting on the premises of the Royal Dublin Society, and the members of the deputation were requested to confer with the Committee of Practical Science on the subject. At the meeting of the Council of the Royal Dublin Society, held on Thursday, the 24th June, 1869, the Rev. the Provost of Trinity College in the chair, the following report from the Committee of Practical Science was read, viz.:—"The Committee of Practical Science beg to report that the deputation from the Natural History Society of Dublin attended the committee, and stated that the Natural History Society was willing to hand over to the Royal Dublin Society its valuable library, with future additions thereto by donations and exchanges, on condition of the Royal Dublin Society assigning for the exclusive use of the former society a suitable apartment, and granting it permission to hold their eight usual scientific meetings in the premises of the latter."

Bathing.

Last year we gave the following hints, which we think it well to republish, several cases of syncope induced by an injudicious use of the open-air bath having come to our knowledge during the past week:—"Avoid bathing within two hours after a meal; when exhausted from any cause; when the body is cooling after perspiration; prevent chilling the body by standing naked on the banks or in boats after having been in the water; don't remain too long in the water, leave it as soon as there is the slightest feeling of chilliness; and do not bathe altogether in the open air, if after having been a short time in the water there be any chillness or numbness. The vigorous and strong may bathe early in the morning on an empty stomach. The young and those that are weak had better bathe three hours after a meal. The best time for such is from two to three hours after breakfast. Those who are subject to attacks of giddiness and faintness, and those who suffer from palpitation and other sense of discomfort at the heart, should not bathe without first consulting their medical adviser."

The Cholera in Gambia.

Letters received from the Gambia state that epidemic cholera, which first appeared at Bathurst on the 25th of May, continued to increase in intensity up to the 22nd, 23rd, and 24th of that month, when the death rate reached the numbers of 75, 74, and 75 respectively per diem. From that date to the 5th of June the mortality gradually declined, the number returned on the last-named day being 24; but the character of the disease continued unchanged, death supervening within two or three hours of the first attack, frequently within half an hour. 1,084 persons had perished in the town of Bathurst alone, out of a population of 4,000. The natives, to whom cholera had been before unknown, are panic-stricken, and it has fallen to a little band of Englishmen, who have hazarded their own lives to stand between the living and the dead, to minister in the hospital and to inter those who have fallen, and this with a thermometer registering from 80 deg. to 89 deg. in the shade. The Governor's own horse has drawn the cart around the town to gather in the dead. No calculation has been made of the number of deaths on either bank of the river Gambia, where it is reported whole native towns have been depopulated and the dead lie in heaps unburied.

New Researches in Cerebroscopy.

M. Bonchut, we learn from the *Union Médicale*, has just presented to the Academy of Sciences of Paris, through M. Dumas, his researches on Cerebroscopy, which he has offered for competition for the Montyon Prize in Medicine and Surgery. He epitomizes his conclusions as follows:—

"The diseases of the spinal cord, such as acute myelitis, spinal sclerosis, locomotor ataxy, &c., produce usually a congestive lesion, and subsequent atrophy of the optic papilla."

"The lesions of the optic nerve produced by spinal disease are the result of a reflex ascending congestive action and they take place by the intercommunication of the great sympathetic."

"The presence of an hyperæmia of the optic nerve of a vascular diffusion over the papilla, and of a partial or total atrophy of this part coinciding with feebleness or numbness of the legs, indicates the existence of acute or chronic disease of the spinal cord."

The Harveian Oration.

THE annual oration in memory of the discoverer of the circulation was delivered in the Royal College of Physicians of London last Saturday afternoon by Dr. Owen Rees. There was a good assembly of Fellows, members, and visitors, who listened to the learned orator with profound attention. Dr. Rees did not confine himself to a mere eulogy of Harvey, but illustrated by his example the mode in which scientific studies should be pursued, and urged his hearers to follow the great example in whose honour they were assembled. Incidentally he stated some of his views, and the present state of medical education, carrying with him the full approval of his hearers. The Medical Council, about to assemble in the same room where Dr. Rees so eloquently expounded some of their duties, would do well to take up the subject in as practical a manner as that which would secure the approbation of such eminent clinical teachers as the Harveian Orator for 1869.

After the oration the President publicly awarded the Baly Medal for Physiology, which the Council of the College had adjudged to Professor Owen, who, being called upon, came forward and briefly thanked the council for this recognition of his labours.

Royal Society of Medicine.

THE proposed amalgamation of the London Medical Societies does not seem certain to be so easily accomplished. Already the Obstetrical Society has found out where the shoe will pinch, and entered a *caveat*. We foresaw this, as our readers are aware, so that we are not surprised. Nor are we disposed to cry out against the accoucheurs as invariably "quarrelsome," as not a few are doing. They may be rather tenacious of each other, but often keep their quarrels to themselves, and certainly in such a case as this have a right to speak and to act. The Medico-Chi. seeks them. They did not seek it, and assuredly they have a right to fix the terms on which they will merge their individuality in the body that desires to absorb them. A bold and just scheme of amalgamation could easily have been effected had the Medico-Chi. taken a decided action in a truly liberal way. This tissue of compromises for the sake of increasing its income will be, unless greatly modified, worth nothing at all.

THE medical men of Birmingham are sending a memorial to the Council, showing the inefficiency of the Medical Act, and urging reforms. As it is sent to every registered practitioner, it will command respect. About 1,000 will probably have signed it by the time this is in the hands of our readers.

A DISCUSSION which touches on a matter of much interest to the profession, has, a few days since, taken place between Dr. Stevenson of Paddington, and Dr. Lankester the coroner, in consequence of Dr. Stevenson having refused to make a *post-mortem* examination of a body. That gentleman having been informed that he was liable to a penalty, was called on for an explanation. He said that he went to the Paddington deadhouse for the purpose of making the examination, but he found no accommodation whatever for carrying it out. Another corpse was on the slab, and the body witness was to examine was in a coffin. He asked the man in charge of the deadhouse to remove the corpse from the slab, and put the other in the coffin in its place, but the man refused, saying it was no part of his duty. Witness conceived it was not his business to shift the corpses about, and he should emphatically decline doing it. Dr. Lankester said the parish authorities ought to provide sufficient assistance to properly arrange the deadhouse. Dr. Stevenson said it was an outrage to remove the body from the house of deceased, as the friends wished the *post-mortem* to take place there. Dr. Lankester did not sympathize with this opinion. He had been agitating for mortuaries for years, because he considered it perfectly disgusting for *post-mortems* to be made in private houses. A juror remarked that the smallness and bad arrangements of the Paddington deadhouse had been the subject of remark at almost every inquest that had been held. The coroner said that, in directing the removal of bodies to that place, he was but administering the law. The inquiry was adjourned, and the coroner directed that the facilities required by the medical gentleman should be provided, if necessary, at the expense of the court.

Correspondence.

SUGGESTIONS IN MEDICINE.—No. V.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Once more I resume the subject of PHTHISIS PULMONALIS, or CONSUMPTION of the LUNGS; but it is not so much for the purpose of making fresh propositions, as to sum up and reiterate my previous suggestions. I would state how I would treat the disease from the commencement to the end, had I the power to carry out my views.

There cannot be a doubt as to the advisability of preventing even the approach of this insidious *monstor horrendum informe*—were it possible. Prevention is always better than cure. And certainly it is the duty of the family physician to point out and assist in all reasonable methods for that purpose. He can never expect a blessing from above on his labours, unless he conscientiously adhere to this maxim, however contrary apparently to his interest. Most certainly the practitioner of the day is not backward in this department. But the physician is usually called in rather to *cure* than to *prevent* disease; in the same way that the surgeon is desired to *set* a broken limb, and not to descant on the causes and mode of avoiding such accidents. Thus, this branch of the subject is generally appropriated by the medical philanthropist, who works at it solely and unremittingly, often to the manifest advantage of the public. Into the causes, therefore, of the malady in question, or the state of the system leading thereto, I do not think it necessary on this occasion to inquire deeply. It has doubtless much to do with the respiration of a vitiated atmosphere. Yet certainly not alone. Cold, wet, insufficient, improper diet, depressing passions, and other things, play no mean part in the drama. Hereditary taint is not to be overlooked. It seems, moreover, as if, in the present condition of humanity, it were quite out the power of man to prevent his fellow-creatures being subjected to such influences more or less. The mass will not attend to its interests in this respect. The scrofulous diathesis will, I fear, ever prevail to a certain extent among some classes of every community, tubercles will be deposited in the lungs, and consumption will follow to the end of the chapter. Our duty is clearly to try and remedy these almost inevitable evils.

The attack of Consumption may bear a similitude to the invasion of a hostile host upon our shores. As it is the interest of every good patriot to check the progress of the enemy at every stage, so it is the duty of both patient and physician to try and stop the onset of the malady at every evolution. The strength and vigour of the constitution, like the *entente cordiale* of neighbouring states, should always be carefully cultivated; while at the same time, any *casus belli*, in the shape of exposure to wet and cold, &c., must be as studiously avoided. Then, when the armada is collected in the form of the strumous diathesis and has set sail upon the systemic ocean, its efforts may be rendered nugatory, for awhile at least, by careful attention to diet and hygiene. The attempt to land or settle on the chest, may perhaps be frustrated by avoidance of exposure, by keeping the parts well covered, and by the inhalation of a tempered atmosphere. Should all this prove ineffectual, however, as will unfortunately too often occur, and the enemy make good his footing—in other words, should the tubercles be deposited in the lungs—then the battle must be fought, and the most persevering efforts made to dislodge him. It is at this crisis that the medical man has usually the first to do with the matter. Something is apparently wrong with the young person. The parents are anxious. The doctor is consulted, and, by careful examination, finds the advanced posts of the invader settled on the soil, although as yet only at the borders. He must not only prevent further inroads, but drive the unwelcome visitor back into the waves, or effect extermination, unless he can make him yield at discretion.

Without metaphor, the physician should make the most strenuous efforts to dislodge the tuberculous matter immediately after its deposition. In no case, perhaps, is delay more dangerous. The value of the time-honoured maxim, *principiis obsta*, is nowhere better exemplified. For this purpose, tubercle should be sought after periodically very early in life, especially where there is an hereditary tendency. The importance of having the lungs of young people frequently explored by means of the stethoscope, can scarcely be overrated. Both male and female children should from time to time be subjected to this ordeal by the family attendant. The seeds of disease early detected may possibly be eradicated.

To do this effectually, I think that the process described in my last letter may be employed advantageously. The little patient, placed upon a revolving couch, should have the head depressed to an angle of 45°, and then be taught to inhale the steam of hot-water in which a portion of acetic acid has been mingled. He would soon be amused with this rather than otherwise. The slightly acid fumes would not excite coughing. Passing into the small bronchi and the air-cells, it would then come in contact with such part of the strumous matter as was lodged therein. This, I have previously explained, is about equal in quantity to that in the parenchymatous structure of the lungs. The acidulous vapour would probably soon dissolve this, and gravitating outwards would be removed by expectoration. Thus a portion of the enemy's forces would be overcome. The rest would probably disappear by the increased absorption induced by the stimulus. In this way, it is to be hoped, the lungs would be effectually cleared from the morbid deposit, and, with the assistance of medicine, strengthened against further inroads.

Should these timely measures have been neglected—should no efforts have been made, or those ineffectually, to clear out the crypts of respiration from tuberculous matter, and this have gone on to softening and excavation—should consumption, in fact, become established in the lungs, I have shown and can only now reiterate, how I should wish this to be treated. It is the full-blown flower, the enemy in full possession, yet still to be combated and probably expelled. If the disease is entirely confined to one lung while the other is quite free and normal, I have councilled that this, the offending member, should, as a *dernier ressort*, be sacrificed, amputated as it were, and made to shrink back beside the spine; while the functions of respiration are maintained, as they well may be, by the other. The mode of effecting this I have explained at length in paper No. 3.

The grand and novel feature in my suggested treatment of Pulmonary Consumption of both lungs, is the revolving couch above alluded to. The *principle* is, to form a dependant opening for the drainage of the numerous abscesses in the organs; the *practice*, that of employing such an apparatus for the purpose. I can but reiterate my firm persuasion that this temporary inversion of the body, together with the inhalation of aqueous vapours offers a fair and reasonable prospect of curing that which has hitherto been regarded as an incurable disease, and that it should be immediately put to the test of experience. Of course this could be done best at an institution devoted to such cases, where the patients are numerous. Three or four couches would at first be amply sufficient, as each sufferer would not occupy one more than for a few minutes at a time, and then would yield his place to another. In private families one would probably be enough.

It remains for me now only to express a fervid hope that these suggestions will meet the eye of those who will read them in a candid and liberal spirit, and have the power to act upon them practically and energetically. To pursue the same beaten track leading nowhere can never be advisable, and must be repugnant to the feelings of the enlightened philanthropist. For the desire for progress marks the spirit of the age. If, then, these original ideas be good, let them not remain a dead letter. Let them be acted on promptly and steadily. As they do not interfere with other practice justly prized, the two sets might often be employed contemporaneously. The new may be added to the old with probable advantage. It is true they do not originate with a man of mark, on whom the world has set its seal, but merely with one who wishes well to his species and to the honourable profession of which he is a member.

Your obedient servant,
TOOGOOD DOWNING, M.D.

Bath: June, 1869.

CASE OF TRAUMATIC HERPES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The neurotic relation of herpes is at present attracting considerable attention, and much valuable information on the nature of this disease has been derived from the investigations, more especially of Hutchinson, Wilson, Paget, and Woakes. Some agreeing with Bürensprung, that the affection is due to irritation of the spinal ganglia, the posterior roots being implicated, whilst others maintaining with Eulenberg that the sympathetic system is the seat of the disease, and that the neuralgia (indeed, all forms of this complaint) are due to affections of the ganglionic or sympathetic system of nerves. These conflicting opinions have been carefully reviewed quite recently in a small work on "Neurotic Cutaneous Diseases," by Dr. H. S. Purdon. I may, however, mention that it is probable that both systems of nerves are equally affected, the sympathetic causing contraction and spasm, the cerebro-spinal dilatation of the capillaries. The following case contains several points of interest:—

R. Echlin, aged 14 years, on Thursday evening, March 13th, 1869, received a blow from a sharp-pointed stone on the back of the head, exactly over the occipital protuberance. He was for a few minutes stunned, but slowly recovered consciousness, being able to walk home, the distance of about a quarter of a mile. The wound was a small contused one, and bled considerably. He took his supper heartily, but when in bed about five hours after the accident, began to become very feverish, and could not sleep. I saw him the next day, had slept little or none, pulse 120 per minute and strong, had a rigor during the night and vomited, pupils widely dilated, great pain in the head, both at the wound and in the forehead, compared it to a cord twisted tightly round the head, the wound was much swollen, cannot bear to have it handled, skin burning and constant thirst. From these symptoms I was afraid of inflammation of the membranes of the brain, and put him upon calomel and compound kino powder, the room to be kept dark and low diet. The next day his gums were "sore," and consequently the mercury was lowered to a grain at night, so as merely to keep the action up. On Sunday, the 16th inst., on visiting him, *herpes labialis bi-lateralis* was exhibited; the eruption was rather extensive, extending from the corner of the mouth upwards and outwards. On the 17th, the mercury was discontinued, and iodide of potassium in infusion of quassia substituted. Wound suppurating, to be poulticed. The next day, Tuesday, the 18th, the right eyelid exhibited an eruption of herpes and much swollen, so that he can with the greatest difficulty raise the lid, the conjunctiva was bloodshot, pain complained of in the supra-orbital notch, appetite improving, mouth better.

The theory of this herpetic eruption is, I think, as follows: the blow from the stone over the occipital bone evidently irritated, if not ruptured, some of the fibres of the fifth nerve, which, as is well known, arises by two roots—one white, the other grey from the front of the crus cerebelli, the apparent origin, for they can be traced through the pons in separate portions down to the olivary tracts of the medulla, or, according to Alcock, to the floor of the fourth ventricle, where they are connected with the anterior and posterior columns of the cord. The fifth nerve in its course outwards forms the Casserian ganglion, which sends off from its convexity the ophthalmic, superior and inferior maxillary nerves. The first gives off the frontal, lachrymal, and nasal, which are concerned in this case with the conjunctivitis and herpes of the eyelid. To the second or superior maxillary is due the herpes labialis, the vesicular eruption being caused by the equilibrium of the vessels being "upset," due to vaso-motor spasm producing redness owing to congestion, which, giving way, the opposite condition—viz., paralysis takes place, there being now no antagonistic power to keep the dilating cerebro-spinal nerves in abeyance, transudation of liquor sanguinis from the vessels occurs, which usually selects the orifice of gland ducts and other vascular spots, and finally gives rise to the elementary lesions known as vesicles, constituting the disease called herpes.

In a paper on Cutaneous Angioneuroses, by Dr. Eulenberg, translated for the Medical Press and Circular by Dr. W. D. Moore, we are informed that herpes zoster presents in many cases, especially of the face, the form of a purely primary vaso-motor neuroses, "In the cases where disturbance of sensibility attend zoster, either as premonitory or concomitant phenomena, the possibility of a reflex origin cannot be excluded. The centre for reflex action is then the ganglion of the sympathetic. In these cases we have to do either with a reflex irritation with consecutive relaxation by peripherically increased irritation of the sensory nerve, or a reflex paralysis in consequence of peripherically lowered irritability."

I remain, Sir,
A Country Practitioner.

◆

A NEW METHOD OF PROCURING EXTENSION IN FRACTURES OF THE FEMUR, DEVISED BY MR. STAPLETON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I notice in a recent impression under the above heading, some remarks made by Mr. Stapleton to his class upon the treatment of fractured femur. He seems to lay claim to originality in the application of what I have for some time known as "the treatment by *continued extension.*" I have lying before me the notes of a case of extracapsular fracture with impaction of the femur, occurring in an old man aged about 60, successfully treated during the session 1867-68, in the Edinburgh Royal Infirmary, by means of this method.

This patient had a further complication of an ulcer in the inner malleolus.

Two broad strips of adhesive plaister were placed, one down the outside of the limb from the hip to a foot-board of suitable size formed of four pieces of wood nailed together to form a kind of frame, the other on the inside from the middle third of the thigh, and secured in like manner to the foot-board as the first. A roller bandage was applied to the whole length of the leg. The foot-board, movable and not in contact with the patient's foot, had attached to it a weight acting over a pulley at the bottom of the bed. The foot of the bed was slightly raised, causing the patient's head to lie a little lower than his feet, by which means extension and counter-extension were secured. In this case the foot-board was made wider than usual, to allow of the ulcer being dressed. The only claim to originality which Mr. Stapleton can make, I think, lies in his retaining the long splint, the utility of which is open to question, as the fractured portions of bone could be retained in opposition by means of the antro-posterior and lateral scored splints, and its use seems to complicate a treatment simple in itself. This method of treating fractures, though not of recent origin, has yet been made more practically useful by American surgeons during the late war, and possesses two great advantages of being less irksome to the patient, and of easier application by the surgeon. Apologizing for trespassing upon your space.

I am, Sir, your obedient servant,
James W. Martin, M.D, M.Ch. J.V.I.

Wooding, Portlaw:
June 4, 1869.

Medical Gleanings.

ANOMALIES OF THE OPTIC THALAMI.

According to Serres, anomalies in the optic thalami, and, according to Breschet, troubles of the anterior cerebral lobes, do not necessarily produce blindness.

WHEN TO TREPHINE.

M. Chassaignac (*L'Union Médicale*) advocates *trephining* in only two conditions: 1st, When there is a lesion situated in a definite spot, the seat of which lesion is fully ascertained, and the effects of which may be suppressed by trephining; 2d, When there are dilated pupils, with symptoms of general compression, which symptoms are tending infallibly to produce death.

SULPHURET OF POTASH IN WHOOPING-COUGH.

Dr. Mackelcan, Hamilton, Ont., was led, from a notice of it which he saw in a French Medical Journal forty years ago, to try this remedy, and his success with it has since been such that he has used no other. He administers it in a mixture of one part of syrup to three of *distilled or rain water*, "the dose being one grain for each year up to four years of age, and after that half a grain additional for each year; the smaller doses being administered in a teaspoonful of fluid, and the larger more diluted, in proportion of the quantity of the salt in each dose. Its beneficial effects are not perceived for five days, when the intervals between the paroxysms of cough become longer, and after that their violence diminishes from day to day, until at the end of ten or fourteen days it is seldom necessary to pursue the treatment further. As the drug easily spoils by keeping, it is important to have it fresh. If it dissolves perfectly in the syrup and water, and the mixture is of a greenish colour, it may be relied on; but if there is any sediment, it has been decomposed by exposure to air, and becomes a sulphate."—*New York Medical Journal.*

RECOVERY FROM THE PASSAGE OF AN IRON BAR THROUGH THE HEAD.

Most of the older practitioners will recollect the following celebrated case, published by Dr. J. M. Harlow, in the *Boston Medical and Surgical Journal*, in November, 1848, and afterwards by Dr. Henry J. Bigelow, in the *American Journal of Medical Sciences* for July, 1850: A man by the name of Gaze, from the accidental explosion of a charge of blasting powder, had a tamping-iron, three feet seven inches long, one and a quarter inches in greatest diameter, and thirteen and a quarter pounds in weight, driven through his head, which was withdrawn by a fellow-workman. The accident occurred in Cavendish, Vermont, on the 13th of September, 1848. The subject of this accident was residing in California when he died, which was on the 18th of May, 1861; between twelve and thirteen years having thus intervened between the date of the injury and his decease. The cerebral organism was comparatively little disturbed by its abrupt and intrusive visitor. During a short period before his death he had several severe convulsions. Dr. Harlow had the enterprise to obtain the cranium and the iron bar; and having exhibited them at the last annual meeting of the Massachusetts Medical Society, has most generously presented them to the Museum of the Medical department of the Harvard University

THE TREATMENT OF CROUP.

The *Wiener Medizinische Wochenschrift* is publishing an extended series of articles entitled "Croup, Diphtheritis, Pseudo-croup, and allied affections of the Pharynx and Larynx, after the Clinical Lectures of Professor Oppolzer, of Vienna." Croup and diphtheria are treated as two entirely distinct diseases by Professor Oppolzer, and croup is regarded as a local disease. From one of the numbers, viz., of October 3rd, 1868, p. 1289, we make the following extract, embodying his treatment of croup. In the beginning, cold compresses are applied to the throat, which are covered by a dry cloth or oiled silk, and changed only every three hours. A tablespoonful of the solution of three grains of tartar emetic, in two ounces of water, is given every fifteen minutes, until repeated vomiting follows. Generally tough mucus and ring-shaped membrane are expectorated, with relief to the child. After the emetic, one of the following powders is given every hour:

℞. Hyd. chlor. mit.,
Pot. iodidi, a a . . . . . gr. duodecim.
Sach. alb., ... oz. unam.
M. exactissime f. p. div. in dos. æquus duodecim.

After the first powders the children usually continue to throw up pseudo-membrane. Then the vomiting ceases, and the condition improves gradually. When the croupy paroxysms and dyspnœa return, which in most cases occurs, the emetic is repeated. In cases of difficult expectoration of the membrane, the vapour of hot water is caused to be inhaled, with or without the nebulizer, and the powders continued. If this treatment is unsuccessful, and the paroxysms and apnœa are about to return for the third time, tracheotomy is to be performed without further delay. Prophylactically, Professor Oppolzer is against keeping children who have once had croup constantly housed up, and spoiling them by too warm clothing, but advises care in observing the wind, and to protect them from the rain, north or north-east winds. Such children should not be outside of the house after sunset. He also recommends cold washings of the throat and chest, with the precaution to dry the skin carefully thereafter, and to prevent the children from exposure to raw temperatures soon after such washings.

◆

Medical News.

Smithfield was the scene of a shocking tragedy on Monday morning, whereby a man named Duggan poisoned his wife, six children and himself, by the administration of prussic acid. The bodies were quite dead when the police effected an entrance into the house. Ill health and other circumstances are said to have been the motives for this diabolical act.

Suit by a Duke's Physician.—The suit between Dr. Déclat, medical adviser of the late Duke of Gramont-Caderousse, and the family of the deceased, has just come before the Imperial Court, Paris, on an appeal from a judgment of the Civil Tribunal of the Seine. This affair has now been pending for three years. The Duke, who died in 1865, when quite a young man, after a short career of dissipation, and without leaving any direct heirs, disinherited his collateral relations, and constituted by will Dr. Déclat his universal legatee, after the payment of a sum of 60,000f. to be applied to a purpose which remained a secret with the doctor. The succession of the Duke, estimated at 2,400,000f., but burdened with debts exceeding 1,500,000f. was valued after the payment of all charges, at between 700,000f. and 800,000f. The relatives of the deceased obtained before the Civil Tribunal the annulment of the legacy to the doctor as an infraction of Article 909 of the Civil Code, which expressly prohibits bequests to a medical adviser made during the final malady. Dr. Déclat then put forward a claim for 200,000f. as his fees during the six years of his attendance on the Duke. The family resisted this demand as exorbitant, and the Civil Court being appealed to, fixed the remuneration to Dr. Déclat as follows, the visits being calculated at 10f. each :—200 in each of the first three years, one visit per day in the fourth and fifth years, and two daily in the sixth, making a total of 20,600f. That sum the heirs offered to pay, but the doctor considered it insufficient, and appealed, as above stated, to the Imperial Court, which has now confirmed the former decision, condemning the apellant to the payment of costs.

University College Hospital.—The annual dinner in connection with this institution was given at Willis's Rooms last week, Prince Christian presiding. The company present was very numerous, amongst them being his Royal Highness Prince Arthur. The usual toasts having been duly honoured, the chairman proposed "Prosperity to the Hospital," and in doing so referred to its present position, and the claim it had upon public support. He said the number of indoor and outdoor patients was not less than 25,000 per annum; the hospital contained 150 beds, of which fourteen were devoted to children under twelve years of age. The surgical and medical staff numbered fifteen, reinforced by eight resident assistants. The nursing staff was admirably supplied by seven sisters from All Saints' Home, and twenty-six nurses. There were, however, two most important facts which he regretted it was his duty to lay before them. One was that the annual income had fallen short of the expenditure to the amount of £4000; and the other was that the debt at the end of the financial year was about £7,000. It was his earnest hope that they would be able on the present occasion greatly to reduce these formidable figures. He hoped also that the time was not far distant when the deficit of which they now had to complain would be altogether wiped off, and that the hospital would continue to progress and confer still greater blessings on the metropolis and the country at large. The subscriptions amounted to £1,800.

THE GRANTS AND APPOINTMENTS OF MEDICAL OFFICERS TO DUBLIN HOSPITALS.

We are reluctantly compelled to postpone till our next the notice of Dr. Mapother's recent communication to the Dublin Statistical Society, and our comments on this subject. The publication of the debate on the Irish Poor-law Superannuation Bill, and of our half-yearly Index, have restricted the space at our disposal.

◆

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

Correspondents not answered should look to the answers the following week.

To Subscribers.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

Dr. J. R. Willan, Haxey.—Your "Cases in Country Practice," shall appear, if possible, in our next.

Dr. Carpenter is thanked for the information kindly furnished, which will be of great service when we have occasion to recur to the subject.

Professor Wilson, Dr. Cockcroft, Dr. Cornish, and Dr. Wilson, are thanked.

Obstetrician.—One grain would be quite sufficient.

Mr. Whatford, Brighton.—If possible, in our next.

Errata.—In synopsis of Cocoas, Taylor Brothers' Pearl should read 8d. per pound.

In the reply to Mr. Eschwege's letter in our last, the comparative prices of Cadbury's and Van Houten's articles should have been divided, the former being 2s. 8d., the latter 4s., and 3s. 6d.

The following Original Communications and Letters are in type, and will appear as soon as space permits:—

On the Treatment of Buboes and their Sinuses (Illustrated), by I. Lamprey, M.B., Surgeon 67th Regiment, Portsmouth.

Remarks on the Temperature of the Air in Upper Canada, by J. P. H. Boileau, M.B., Surgeon 29th Regiment.

Obstetric Cases, by J. R. Willan, M.D., Haxey, Lincoln.

A Curious Exit for a Pin, which was swallowed fourteen months previously, by Francis McEvoy, L.K.Q.C.P., M.R.C.S.Eng., &c., Balbriggan.

A Worm Discharged through an Abscess, by the same author.

On Epidemic Visitation of Jaundice, by Thos. Hayden, F.R.C.P., &c.

Endoscopic Examination of the Womb, by Dr. D. Commander Pantaleoni, Nice.

Prostitution and its Causes, a Letter by R. J. Kinkead, A.B., L.M., T.C.D., &c.

Communications, Enclosures, &c., have been received from Mr. Samson Gamgee, Birmingham; Dr. Paine, Philadelphia; Dr. Cree, Portsmouth; Dr. Hayden, Dublin; Dr. Gordon; Dr. Toogood Downing, Bath; Dr. Spencer; Dr. Clark; Dr. D. Commander Pantaleoni, Nice; Dr. Charleton, Gloucester; Dr. Gavin, Boston; Mr. J. P. Coldstream, Edinburgh; Mr. Craddock; Dr. Peirson, Scarborough; Dr. Quinan, Dublin; Mr. Cresswell, Steeple Aston; Mr. Baker Brown; Dr. Craister, Bramley; Mr. Tichborne, Dublin; Dr. Crew, Wansford; Dr. Dudfield, London; Mr. Cobbold, Dedham; Dr. Pearson, Kensington; Mr. Savory; Dr. Julius Althaus, London; Dr. Cotterell; Dr. Barr Meadows, London; Dr. Cresswell, Norwood; Dr. Carpenter, Croydon; Dr. J. R. Willan, Haxey: Dr. Thos. Wilson, Leith; Dr. Crothers, Westbourne; Dr. J. Woods Beck, Belfast; Dr. Cornish, Taunton; Dr. Cockcroft, Todmorden; Dr. Clarke, Manchester; Sir John Gray, London; Dr. Thorowgood; Mr. F. B. Courtenay, London.

A Subscriber, Kingstown, is informed that the lists of the successful candidates for the last M.B. examination at the University of Dublin do not appear in our columns, simply because neither that nor any other information respecting the medical arrangements of Trinity College are ever forwarded to us for publication. We do not conceive that the doings of the Dublin University or any other medical school are of such general interest to the profession as to make it necessary for us to solicit a record of its proceedings, which, nevertheless, we should be pleased to publish if they were furnished to us as are the returns from the London colleges.

We have received from Messrs. Macniven and Cameron, of Edinburgh, a sample box of their newly registered pens, styled the Waverley, Owl, and Pickwick Pens. The improvement claimed over the ordinary steel pens is in the peculiar mode of manufacture. In the Waverley and Pickwick pens the points are turned up, to prevent catching in the paper by rapid writing, the former answering to the requirements of the quill. In the Owl pen the point is reversed, and is well adapted for very fine writing. Our readers would probably prefer the Waverley. They are, however, all admirable in their way, and need not the poetic puffing indulged in by some journals to recommend them.

"THE RELATIVE VALUE OF COCOAS."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am sorry I have once more to recur to your observations as to the relative value of Van Houten's cocoa.

In last Wednesday's publication you try to prove that because your analysis makes Cadbury's Cocoa Essence and Van Houten's cocoa almost identical, the former must, according to retail price, be the cheaper one.

Now, I need not tell you that two articles may by their analysis be found, or judged to be, quite identical, and that taste and smell will still detect, where analysis fails, a most marked difference in quality, and, therefore, in value. Such a difference does not seem to have entered into your calculation, and you will allow me to complete the comparison by stating that one ounce of Van Houten's cocoa goes as far as two ounces of Cadbury's Cocoa Essence, and produces still a superior beverage. I leave it to anyone to ascertain the fact for himself, and to judge whether or not it is the cheaper one.
